

- Int-Wr is write of intermediate matrix in aggregation phase and Int-Rd is read of Intermediate matrix in combination phase.
- SP dataflow does not have Global Buffer Intermediate accesses, since the second phase uses the data locally in PE.
- SP dataflow has partial sum accesses because T_F features are processed at once and then phases are switched. Therefore, partial sums are produced
- Aggregation accesses are same across intra-phase dataflows since, there is not much reuse in sparse dataflows. One exception is SP dataflow where the intermediate matrix is stored locally and not written to Global Buffer
