The Greek text string is first processed by stripping off any accent or breathing mark and returning the base letter to lower case. While iterating through all characters in the text, when a space or new line character is reached, the previous word captured is added to a list. A word is not added to the list if it has previously been added to the list or the length of the word is less than a number for which the program allows specification. The result of this method is a list of those unique Greek words which appear in a chosen Greek text.

The Latin text string is first processed by converting all letters to lower case and taking account of the rules of elision and pronunciation. Similar to the Greek processing, the processed Latin text is converted into words. Each Latin word in the list is processed to determine if part of the word should be elided, based on the starting letter of the next word. The final step is to condense all the Latin words together into one text string without spaces, while keeping a list of the starting position of each word in the text string.

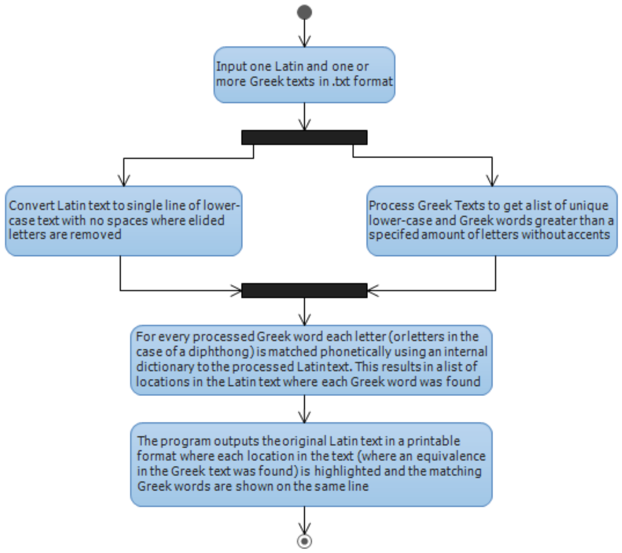
Once the two processing methods reach completion, the model has the list of unique Greek words and a string of Latin words, including the starting position in the original text of each word. The final processing method compares the Greek words to the Latin text string to find matches and returns a list of matches, which include the starting position of the match, ending position of the match, and the Greek word that matched. First, each letter of every Greek word is converted to a list of possible Latin characters or pairs of characters. A dictionary exists that for each base Greek lower case letter there corresponds a list of Latin letters or pairs of letters. Similarly, the existence of a diphthong is determined by referencing the values of a Greek-Latin diphthong dictionary. Both dictionaries were developed by examining those grammars and references noted earlier. By iterating though every Greek letter in a Greek word the possible Latin letters can be looked up in the dictionary, and, if the current letter and next letter in the Greek word are in the diphthong dictionary, this will override the regular dictionary lookup function. Once a list of every possible Latin correspondence for every letter in a Greek word exists, all permutations of letters are returned in a list of strings. This list is the list of every possible Latin series of characters that could match a Greek word. Using a regular expression every match in the Latin text string is found based on the previous list. These results are returned as a list of Greek words, including the starting and ending position in the original Latin text of the match.

The unique list of Latin-to-Greek results is returned to the view and is displayed in a grid, which can be sorted alphabetically, wherein the left column contains the uncompressed Latin character matches and the right column the Greek word equivalent in Greek characters. Also, a flow document is created which contains the original text with the matches highlighted in yellow and the matching Greek words to the right for each line. The Greek words in brackets are words that correspond to the same Latin text location, thus assisting the program user in contextualizing and applying significance to the results.

Results and applications

Through operation of the software, possible candidates for Greek puns within various Latin authors have been identified. By cross-referencing open-source texts of Vergil's *Aeneid* and the *Carmina* of Catullus with the Homeric epics and *Argonautica,* we have discovered hereto unnoticed Greek words, the meanings of which often correspond to the thematic concerns of the passage. Considering the limited extent of the search, both in duration and in those texts analyzed, these results seem to suggest that there are a considerable number of Greek puns remaining to be found within the corpus of Latin literature. While we are currently still in the process of refining the software and in consideration of more comprehensive ways to cross-reference Greek texts, we are still looking to expand the search both towards those texts already analyzed and to other Latin authors. With a view to the future, it is our hope that this software will eventually become available for public use and that it can lead to a more nuanced view of the role which Greek culture and language plays in Latin literature.

Program diagram



Input one Latin and one or more Greek texts in .txt format
Convert Latin text to single line of lower-case text with no spaces where elided letters are removed
Process Greek Texts to get a list of unique lower-case and Greek words greater than a specifed amount of letters without accents
For every processed Greek word each letter (or letters in the case of a diphthong) is matched phonetically using an internal dictionary to the processed Latin text. This results in a list of locations in the Latin text where each Greek word was found
The program outputs the original Latin text in a printable format where each location in the text (where an equivalence in the Greek text was found) is highlighted and the matching Greek words are shown on the same line

The study of newspaper layout evolution through historical corpora has been addressed by diverse qualitative and quantitative methods in the past few years (Antonacopoulos et al, 2013; Gonzalez et al, 2001; Liu et al, 2001; Mitchell and Hong, 2004; Singh and Bhupendra, 2014). The recent availability of large corpora of newspapers is now making the quantitative analysis of layout evolution ever more popular. This research investigates a method for the automatic detection of layout evolution on scanned images with a factorial analysis approach. The notion of eigenpages is defined by analogy with eigenfaces used in face recognition processes. The corpus of scanned newspapers that was used contains 4 million press articles, covering about 200 years of archives. This method can automatically detect layout changes of a given newspaper over time, rebuilding a part of its past publishing strategy and retracing major changes in its history in terms of layout. Besides these advantages, it also makes it possible to compare several newspapers at the same time and therefore to compare the layout changes of multiple newspapers based only on scans of their issues.

Introduction to the Corpus

The corpus consists of digitized facsimiles of two Swiss newspapers, "Journal de Genève" (JDG) from years 1826 to 1997 and "Gazette de Lausanne" (GDL) from years 1804 to 1997. Scanned daily issues of each journal were transcribed using an optical character recognition (OCR) system (Rochat et al, 2016). The entire scanned data weighs more than 20TB, which makes most usual analysis techniques out of reach for regular desktop computers. This corpus has been the focus of several studies analyzing textual data (such as linguistic changes (Buntix et al, 2016) and named entity recognition (Ehrmann et al, 2016)). An example of different layouts of GDL's first page is given in Figure 1 which shows the evolution of various features, such as title size and position, fonts and number of columns.

Bitmap Factorial Analysis

In order to analyze layout evolution, we propose to build a static layout representation for every year in the corpus. Thus, when studying each newspaper's first page, we define the pixel t of the static representation $\overline{P_{y,m}}$ of month m of year y as

$$\overline{P^t_{y,m}} = \frac{1}{N_{ym}} \sum_{d=1}^{N_{ym}} P^t_{y,m,d}$$

Where N_{ym} is the number of issues in month m of year y and $P_{y,m,d}$ is the first page of day d of month m of year y. The pixel t of the static representation $\overline{\overline{P_y}}$ of year y is then defined as

$$\overline{\overline{P^t_y}} = \frac{1}{N_y} \sum_{m=1}^{N_y} \overline{P^t_{y,m}} = \frac{1}{N_y} \sum_{m=1}^{N_y} \frac{1}{N_{ym}} \sum_{d=1}^{N_{ym}} P^t_{y,m,d}$$

Were N_y is the number of month representations $\overline{P_{y,m}}$ in year y.

A diagram of the process is shown in figure 2.

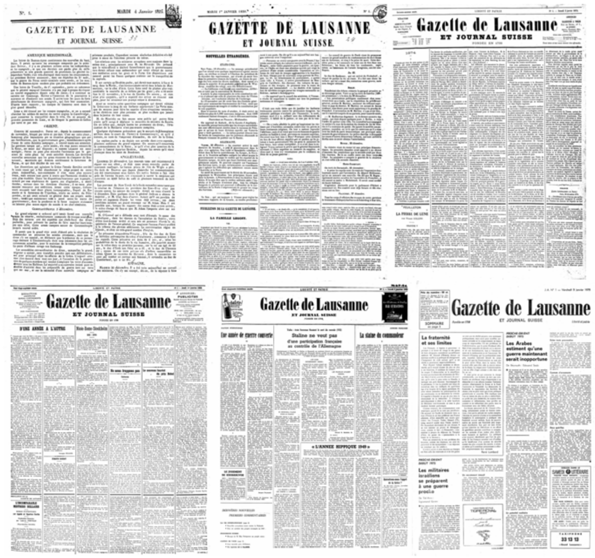

Figure 1. Different layouts of GDL in years 1825, 1850 and 1875 (top, left to right), 1925, 1950 and 1975 (bottom, left to right).

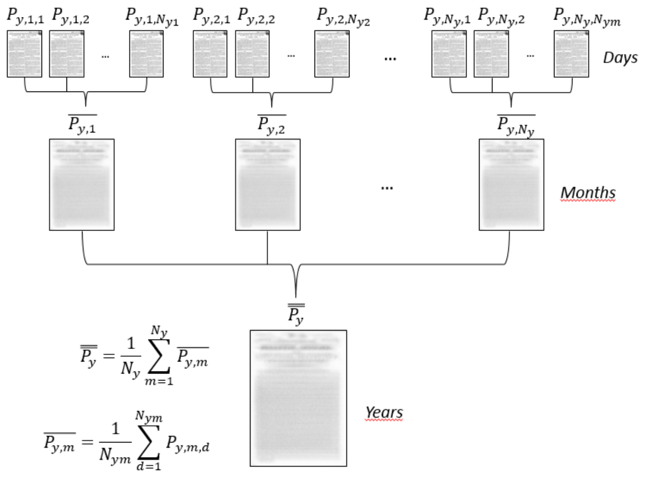

$P_{y,1,1}$ $P_{y,1,2}$ $P_{y,1,N_{y1}}$ $P_{y,2,1}$ $P_{y,2,2}$ $P_{y,2,N_{y2}}$ $P_{y,N_y,1}$ $P_{y,N_y,2}$ $P_{y,N_y,N_{ym}}$
Days
$\overline{P_{y,1}}$ $\overline{P_{y,2}}$ $\overline{P_{y,N_y}}$
Months
$\overline{\overline{P_y}}$
$\overline{\overline{P_y}} = \frac{1}{N_y}\sum_{m=1}^{N_y}\overline{P_{y,m}}$
$\overline{P_{y,m}} = \frac{1}{N_{ym}}\sum_{d=1}^{N_{ym}}P_{y,m,d}$
Years

Figure 2. Process diagram creating a yearly representation of first page layouts.

These representations give a vision of the mean layout over the course of a given year. Each yearly representation can be projected in a two-dimensional space by performing a principal component analysis (PCA) which maximizes the covariance on every pixel. This method is analogous to the eigenfaces method used for face recognition (Turk and Pentland, 1991a, 1991b) We compute the eigenvectors, that we named eigenpages, as well as the eigenvalues of the covariance matrix of the pixels. The yearly representations are then projected in the two-dimensional space of the two eigenvectors which have the highest eigenvalues. The resulting projections of yearly mean images of JDG and GDL from years 1900 to 1998 are portrayed in Figure 3. In these figures, each point is a yearly image and consecutive years are linked in order to highlight the change over time. The further apart the points are, the bigger the layout's changes occurring between two years. Visual inspection reveals several clusters of years with a similar layout. Furthermore, homogeneous sequences of years may be clustered automatically based on the (unprojected) distance between them (e.g. by computing the distance between year *y* and *y*+1 and "cutting" the sequence of years at positions where their distance exceeds an arbitrary threshold.

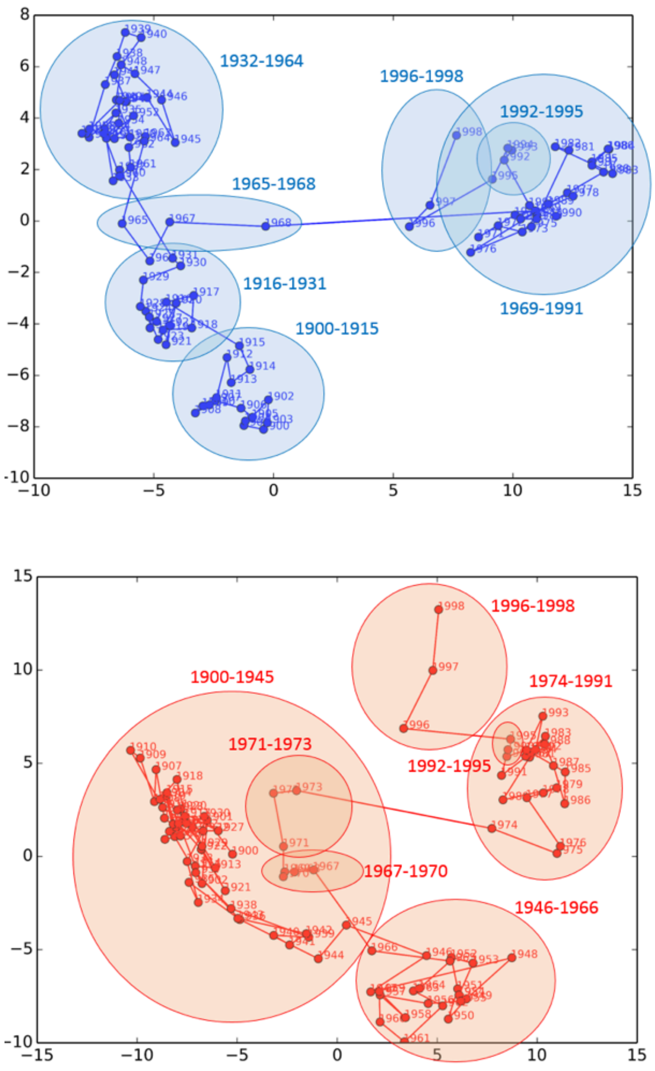

Figure 3: PCA projected results of the yearly representations of first pages of JDG (top, blue) and GDL (bottom, red) from years 1900 to 1998 with clusters obtained by visual inspection.

Discussion

The PCA technique allows us to quantify layout changes by covariance analysis of the pixels of yearly representations. The proportion of covariance information shown by the PCA is 73% for JDG and 76% for GDL. Visual interpretation reveals different chronological clusters which are displayed in Tables 1 and 2 along with their mean positions in the two-dimensional space of eigenpages as well as mean images representing these periods (computed in the same way as yearly images, cf. Figure 2). These mean images reveal the major layout transitions in each journal which may be summarized as follows:

Journal de Genève (JDG):

- 1900-1915: 6 columns, title above columns 2 to 5, little space between columns.
- 1916-1931: 4 columns, title above columns 1 to 4, more space between columns.
- 1932-1964: 4 columns, change of the layout around the title and the first title position.

- 1965-1968: 4 columns, change of the layout around the title, boxes with black borders begin to appear.
- 1969-1991: 4 columns, total change of the title, title above columns 2 to 4, logo appears, more space between columns and boxes, article titles are bigger.
- 1992-1995: 5 columns, fusion of JDG and GDL, big change of layout, boxes inside boxes begin to appear, more stable structure.
- 1996-1998: 6 columns, big change in title font, previous column layout replaced by a more classic one, article titles are placed at the top of the first page.

Gazette de Lausanne (GDL):

- 1900-1945: 6 columns, title above columns 2 to 5, little space between columns.
- 1946-1966: 7 columns, title above columns 2 to 6, more space between columns yielding particularly small column sizes.
- 1967-1970: 5 columns, title above columns 2 to 5, first column begins before the title which is on the right, advertisements placed below the page.
- 1971-1973: 6 columns, more classic layout with article titles at the top.
- 1974-1991: 4 columns, lots of space between columns and articles, bigger article titles.
- 1992-1995: 5 columns, fusion of JDG and GDL, big change of layout, boxes inside boxes begin to appear, more stable structure.
- 1996-1998: 6 columns, big change in title font, column layout replaced by a more classic one, the article titles are placed at the top of the first page.

The automatic clustering method described in previous chapter has been applied on unprojected distances and produce similar clustering results (depending on the threshold parameter). Qualitative analysis confirms that the resulting clusters are all separated by important layout transition phases.

Journal de Genève	1900 – 1915	1916 – 1931	1932 – 1964	1965 – 1968	1969 – 1991	1992 – 1995	1996 – 1998
Eigenpage 1	-1.5858	-4.5761	-6.3541	-4.0387	11.5680	9.6320	6.6127
Eigenpage 2	-6.9613	-3.4511	4.0575	-0.4756	0.9258	2.3969	1.2411

Table 1: Chronological clusters with their mean first page representations and their positions in the axes of PCA eigenpages (JDG). PCAPCgenpag(JDG)obtained by PCA for JDG.

Gazette de Lausanne	1900 – 1945	1946 – 1966	1967 – 1970	1971 – 1973	1974 – 1991	1992 – 1995	1996 – 1998
Eigenpage 1	-6.7016	4.5705	-2.1566	-2.6345	9.8505	9.5849	4.3915
Eigenpage 2	0.4252	-7.1833	-0.8661	2.4913	3.9961	6.3149	10.0302

Table 2: Chronological clusters with their mean first page representations and their positions in the axes of PCA eigenpages (GDL).

This analysis is also useful to compare several newspaper publishing strategies. We projected the two newspapers in the same two-dimensional space representation (presented in Figure 3) using the same method with yearly representations of both journals in order to compare their chronological trajectories. The covariance information shown by the PCA is 67%. Visual inspection reveals three main clusters for each journal. Each of these clusters turns out to correspond to groups of clusters that has been detected in the previous projections. We observe that the layout of both journals has evolved in a similar way but with different timescales. GDL is more dispersed than JDG and has explored different strategies during the period 1900-1966. However, GDL has adopted a style more similar to JDG style between 1967 and 1973 just before it entered a major layout transition in 1974 (5 years later than JDG).

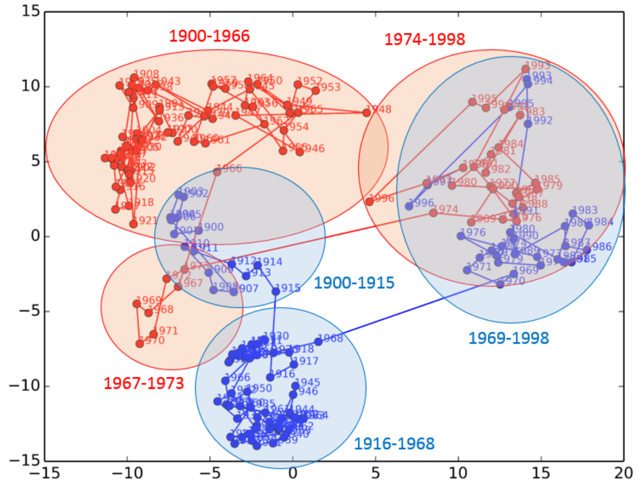

Figure 4. PCA projected results of the yearly representations of first pages of JDG (blue) and GDL (red) from years 1900 to 1998 in the same two-dimensional space representation with clusters obtained by visual inspection.

Conclusion

These first results demonstrate a promising method of detecting layout evolution automatically. The method is applicable to a large variety of longitudinal image corpora without any prerequisites, since it only requires images in bitmap format. It makes it possible to compare several corpora and determine periods of layout transitions in a common two-dimensional space for visual interpretation. In addition, unprojected distances can be used to determine layout changes in an entirely automatic fashion, by analyzing the representation space through clustering algorithms. Future work on this method should include the integration of an alignment method in the bitmap preprocessing step, because alignment errors may impact the pixel covariance analysis and eigenpages creation.

La réception de l'édition critique numérique : accès multiples pour publics divers?

Joana Casenave
joana.casenave@umontreal.ca
Université de Montréal, Canada

Yves Marcoux
yves.marcoux@umontreal.ca
Université de Montréal, Canada

Introduction et cadre conceptuel

L'édition critique numérique, part active des Humanités numériques, bénéficie aujourd'hui d'un temps de recul suffisant pour dresser les premiers bilans des travaux édités sur le web. En effet, les premières éditions numériques ont aujourd'hui près de 20 ans : Peter Robinson a entrepris son projet d'édition des *Canterbury* Tales (*Les Contes de Canterbury*, au nombre de 24, ont été écrits par Geoffrey Chaucer au XIVe siècle. Le texte est écrit en moyen anglais et en vers) en 1993 pour en livrer une première version sur Cd-rom en 1996. De même, c'est en 1993 que Jerome McGann a lancé son projet *The Rossetti Archive*, avec l'objectif d'éditer l'ensemble de l'œuvre de l'écrivain anglais Dante Rossetti (1828-1882, peintre et écrivain britannique).

D'ailleurs, les éditeurs numériques eux-mêmes se plient régulièrement à l'exercice d'analyse de leur méthode (McGann, 2010 ; Robinson, 2004, 2010). Leurs réflexions sont nourries par leurs propres expériences et elles tirent également profit des études menées par les chercheurs spécialisés en Sciences de l'Information et en Humanités numériques qui s'appliquent, depuis quelques années, à théoriser l'édition critique numérique (Apollon *et al.,* 2014, Burdick *et al.*, 2012, Pierazzo, 2015, Sahle, 2013, Vanhoutte, 2010).

Au cours de cette présentation, nous allons précisément nous appuyer sur cette littérature analytique pour nous intéresser à la question de la réception et de la prise en compte de publics divers dans les éditions numériques.

Problématique

De fait, contrairement aux éditions critiques publiées sur papier, les éditions numériques semblent bénéficier d'un avantage certain : il s'agit de la possibilité offerte à l'éditeur de multiplier les voies d'accès au texte qu'il édite.

Dans une édition critique traditionnelle, publiée sur papier, l'éditeur propose une voie d'accès unique, qui prend forme dans son texte final établi, résultat de son interprétation critique des manuscrits témoins étudiés. Il adresse son édition à un public donné et travaille ensuite à rendre son étude conforme aux attentes de ces lecteurs préalablement identifiés. Pour qu'un même texte soit adressé à des publics divers, les éditeurs sont contraints de multiplier les éditions, ciblant un lectorat précis à travers chacune d'elles : les étudiants et leurs professeurs dans le cadre universitaire ; les chercheurs ; un public élargi, intéressé par l'édition savante des grandes œuvres.

Dans l'édition numérique, le format d'encodage XML/TEI permet de multiplier les niveaux d'information dans un même texte. L'éditeur peut ainsi coder des informations analytiques très diverses et choisir ensuite, de les présenter, ou non, aux lecteurs. Ce faisant, il peut décider de cibler plusieurs types de réception en adéquation avec les niveaux d'informations analytiques encodées. Il lui est alors possible de proposer les accès multiples et diversifiés qui répondent le mieux aux attentes des lecteurs ciblés.

Généralement, les projets d'éditions critiques numériques rassemblent, dès leur conception, des philologues pour établir le texte et des informaticiens pour s'occuper de la publication web et de l'élaboration de la plateforme de consultation. Ces équipes interdisciplinaires traitent à la fois les questions de philologie et les aspects liés à l'ergonomie et à l'« utilisabilité » de l'édition critique en cours de préparation. Désormais, dans le monde de l'édition numérique, le travail réalisé sur la réception de l'édition et l'accompagnement du lecteur est tout aussi important que la traditionnelle valorisation des sources philologiques.

La question qui nous occupe est donc celle de la prise en compte réelle de la diversité des publics dans l'édition numérique. Les outils techniques donnent – théoriquement du moins – la possibilité de multiplier les accès aux textes en fonction des lectorats. Qu'en est-il exactement ? Les éditeurs parviennent-ils réellement à multiplier les voies d'accès aux œuvres proposées ? Comment prennent-ils en compte, dans la préparation de la réception, la diversité des lecteurs et de leurs attentes ?

Méthodologie

L'édition numérique se situe pleinement dans le champ des Humanités numériques et, pour étudier cette question de la réception, nous allons adopter une méthodologie propre à ce champ disciplinaire, qui allie recherche et expérimentation.

Notre présentation se déroulera donc en deux temps. Nous allons tout d'abord mener une étude analytique sur un corpus d'éditions numériques sélectionnées à cet effet. L'objectif est de caractériser le positionnement des éditeurs numériques et d'observer les moyens qu'ils mettent en œuvre pour parvenir à cibler des publics différents sur une même plateforme de consultation des contenus, en proposant pour chacun d'eux des informations propres.

Ensuite, dans un deuxième temps nous présenterons les propositions concrètes que nous avons pu développer sur un petit corpus d'expérimentation. Au cours de la réflexion que nous avons menée sur une édition numérique d'un corpus de textes médiévaux, nous avons en effet cherché à multiplier les niveaux de réception et les modes de présentation des informations analytiques, en fonction de nos publics-cibles.

Résultats attendus

Partie I – analyses d'éditions numériques existantes

Pour étudier cette question, nous allons tout d'abord analyser un corpus d'éditions numériques sélectionnées par choix raisonné. Nous avons constitué un corpus de quatre éditions numériques qui se démarquent, dans le paysage éditorial contemporain, par l'attention portée, par les éditeurs, aux publics multiples. Les éditions critiques numériques retenues pour notre corpus d'observation sont diverses puisqu'elles portent sur des documents d'archives comme sur des œuvres littéraires.

Pour mener notre étude, nous avons élaboré une grille d'observation. Cette dernière est concentrée sur trois pôles : le texte édité, les outils de navigation et recherche, les outils de communication et de travail participatif proposés aux lecteurs. Les éditeurs y manifestent les particularités propres à chacun des publics cibles et y présentent des informations adaptées à chacun d'eux.

Les observations que nous ferons nous permettront alors de dégager des tendances et caractéristiques des éditions numériques afin de comprendre comment les éditeurs organisent, dans les plateformes de consultation de leurs éditions, les réceptions multiples.

Partie II – expérimentation sur un corpus littéraire médiéval

Dans un deuxième temps, nous allons confronter notre réflexion à notre propre travail d'expérimentation. La question des publics a été au centre de nos préoccupations lors de l'élaboration de notre édition numérique, et nous avons développé un schéma d'encodage permettant, précisément, de faire coexister des niveaux de réception multiples. Nous avons encodé et préparé la réception d'un ensemble divers d'informations analytiques : variantes philologiques, informations de critique littéraire, informations contextuelles. Ces informations sont alors présentées de manière coexistante mais distincte : certaines sont préparées en direction du public philologue spécialiste, d'autres en direction d'un public littéraire averti, d'autres en direction du grand public. Nous allons présenter notre édition actuellement en cours de réalisation, et expliciter la mise en place des niveaux de réception tels que nous les avons élaborés dans notre travail.

L'objectif de cette communication est ainsi de participer à une réflexion sur l'accès multiples aux textes ainsi que sur la prise en compte des niveaux de réception dans la préparation des éditions numériques.

Introduction

The Transforming Musicology project began in 2013, with funding from the UK's Arts and Humanities Research Council. It had three primary aims: to explore how technology could enhance, and perhaps 'transform', the practice and dissemination of conventional musicological research; to explore how large, new online sources of information, such as social media, might be exploited by digital musicology; and to look, in a modest way, at how digital approaches might be adopted in a sustainable way by the musicological community and beyond.

In this paper, we give an overview of the project and how it developed, discuss our strategy for approaching these goals, and reflect on how an inclusive strategy for both research and teaching can be effective, despite its organisational and financial costs.

The Transforming Musicology research project

Conventional musicology is represented in the project by two research strands, one drawing on music from the early modern period and with an emphasis on corpus-based research, and the other considering both the psychological perception and the historical reception of Wagner's use of leitmotifs, centred on his Ring cycle. The project also funded four mini-projects, selected from an open call, to extend the range of research that Transforming Musicology could cover. These, like our research on musicology of online communities, could then be treated as case studies for an analysis of technology needs and overlaps, points of connection, workflows and the areas where connective technologies such as Linked Data might be most effective.

The **early modern** strand of our project builds on two corpora: Early Music Online (EMO), scanned images and metadata for 300 sixteenth-century printed music books owned by the British Library; and the Electronic Corpus of Lute Music (ECOLM), a collection of full-text encodings and metadata for lute music. These contain closely interrelated music, and Optical Music Recognition tools were used to support the extraction of musical information from the facsimile images. Additional funding supported the creation of an open Linked Data union catalogue connecting the resources to one another and to relevant external resources, and the creation of a prototype application that supports both the linking process, and the publishing of web pages based on the now-linked resources. In collaboration with the BBC (the UK's national broadcaster) this resulted in demonstration pages for a BBC radio programme, the Early Music Show, allowing navigation of broadcast programme information, enriched with images and information from EMO, ECOLM, DBPedia and other sources of Linked Data (Weigl et al., 2016). Meanwhile, the musical content can be analysed to explore the creative process of arranging the vocal music of EMO for the lute, as seen in ECOLM (Lewis, Crawford & Müllensiefen, 2016)

The **Wagner** research strand has two elements. Firstly, we are exploring the early development of guidebooks and other media aimed at helping listeners recognise and follow the so-called leitmotifs in Wagner's four-opera cycle, Der Ring des Nibelungen. These diverge from the composer's own description of the use of motifs in his works, and tease out different aspects of the musical and dramatic themes of the works. In addition to the musicological question here, we also investigate whether a semantic web ontology can usefully represent the diversity of motifs, their different expressions and their relationships (Rindfleisch, 2016).

The second Wagner element is psychological, with biometric readings taken from audience members during performances of all four operas of the cycle. Along with memory tests, these provide us with a huge amount of data to interpret, and challenges for how to publish that data in ways that are useful to others. Further to this real-time physiological data, we also have expert annotations of a score, recording performance aspects that might be significant in the subject responses but not recorded in the notation, along with a complex set of information for aligning the time-based responses with each other and with a musical score (Baker & Müllensiefen, 2016).

A vast quantity of music of all kinds has become available on the web during recent decades and has engendered a correspondingly large amount of commentary, whether simply in the form of 'likes', or through intense online discussion on specialist websites to sophisticated scholarly articles. We carried out a pilot investigation of **user communities** on a lyric-annotation website, genius.com, formerly Rap Genius. With over 3,000,000 annotations, this can be regarded as a paradigmatic and valuable musicological resource which needs to be approached with the techniques of Big Data; our work has been centred on the overlaps between the networks of annotators and the songs and artists they annotate (Fields & Rhodes, 2016).

The four **mini-projects** have contributed: audio analysis of historical electronic music; ornamentation style in traditional Irish flute playing (Jančovič, Köküer, and Baptiste, 2015); a big data approach to finding the sources of the poetry used in medieval sacred songs; and an exploration of 18-20th-century London musical life based on digitised concert information from programmes and newspapers (Dix et al., 2014).

For these investigations, we have evaluated how **semantic web technologies** may offer solutions for bridging between disparate data and tool sets, and help document the research and its data, making it more reproducible as a result. (Nurmikko-Fuller and Page, 2016)

The Transforming Musicology website's Publications section offers a more complete list of research outputs than can be covered here.

We have embedded engagement with technology, musicology and other music-related communities in our work in general, but the most significant step for us in ensuring sustainability for digital musicology has been the creation of a week-long digital musicology workshop as part of the Digital Humanities at Oxford Summer School. The summer school is the largest of its kind in Europe, and is made up of a framework programme, consisting of a morning session each day, after which students attend the more specialist workshop they have selected.

By summer 2017, this will have run in three consecutive years and attracted a diverse set of over fifty students.

Teaching Digital Musicology at the Digital Humanities at Oxford Summer School

Although courses do exist on specialist areas within musicology (such as the Music Encoding Initiative summer school in Paderborn) this is the first dedicated to the whole discipline. In designing the curriculum, the Transforming Musicology team have reflected on how we can best make the methods that we have investigated over the course of the project – along with others that we know are used and work well – readily accessible to the wider musicology community.

Just as we have endeavoured to be inclusive in our approach to the musicological research that we have undertaken and supported within the project, we have also sought to create a space in which musicologists can be introduced to, and given the opportunity to experiment with, a wide variety of tools and approaches. It is important to us that the questions that musicologists investigate are not distorted when technology is brought to bear, and our teaching reflects this by balancing sessions about general-purpose tools with domain-specific use-case descriptions.

Students are eased into the week with an introduction giving an overview of the week ahead, but also some personal reflections about moving into a digital musicology approach from a more traditional background, and each day begins with presentations of case studies to motivate the techniques introduced during that day. Each day broadly considers a single topic, covering audio processing on both a small and large scale, music encoding, Optical Music Recognition and music processing. The final day presents more case studies and closes with a round table discussion which is intended to give the students the opportunity to reflect on the week and their own research practice and consider if and how the skills that they have learned can be useful to them.

The workshop is intended to stimulate ideas rather than to make programmers and audio engineers of our students, although we do still expect students to perform simple programming tasks and introduce them to key audio concepts and tools. Such lofty, long-term goals are difficult to evaluate. We take immediate feedback through a form on the last day, although the longer-term effect of attending can only be seen as the students develop their research in the coming years. Shorter-term impacts, including collaborations with tutors on papers and research proposals, and increasing contributions to conferences and workshops with an explicitly digital aspect can already be seen.

Musicology has always been interdisciplinary in nature, and has been transforming itself based on contributions from computing and web technology for over fifty years. We see our project as contributing to and supporting that transformation, both through our own research and through developing the skills of others.

Acknowledgements

Transforming Musicology is funded by the UK Arts & Humanities Research Council (ref: AH/L006820/1) and has benefitted from many contributors. The Transforming Musicology website lists the core researchers and investigators, the advisory panel, and mini-project

researchers and investigators. Similarly, there is too little space to acknowledge tutors, speakers and organisers for the summer school, but their contributions have informed the above discussion in many ways.

The Extended Language of Religious Reform: Marking Up a Register for Early Modern Sermons

Thomas Winn Dabbs
tdabbs@cl.aoyama.ac.jp
Aoyama Gakuin University, Tokyo, Japan

This talk will report on the formation of an online open source register for early modern English sermons, a collaborative effort that includes scholars and technical experts from North America, the United Kingdom, and Japan. The need for a digital register of early modern sermons is abundantly clear to scholars who specialize in the history of the church and religious practice. Sermons were, for better or worse, central to efforts to broadcast and enforce disquieting religious reforms and to address the unsettling controversies in religious practice during the early modern period. It should be stressed, also, that a well-constructed and user-friendly platform of this nature would reach the many among the general public who are interested in the history of religion in general and in Christian church history in particular.

The term register is used here to denote a comprehensive and searchable list of English sermons, sermon events, and related sermon information from a variety of contemporaneous records and sources during the period 1500 to 1700, including sermons delivered to English audiences in Latin will also be catalogued. This project will not attempt to digitalize full texts of print or manuscript sermons.

Extant sermons were often printed long after they were delivered and many remain separately catalogued in manuscript. Non-extant sermons are known about from disparate sources: chronicles, diaries, private correspondence, and records of church and state. This lack of cohesion creates something of a vacuum amidst a plethora of sources that make reference to preaching in general and also to individual sermons. The goal of this project, therefore, is to bring to a list of sermons the cataloguing and search functionality (on a much smaller scale) that the British Library Short Title Catalogue (ESTC) online currently affords printed works.

There have been efforts recently to explore and document sermons during this period in digital formats but with differing objectives. These efforts include digital platforms in early development such as the announcement to 'Gateway to Early Modern Manuscript Sermons' (GEMMS), as well as digital projects such as The *St Paul's Cathedral Project* (formerly the Virtual Paul's Cross Project) and John Foxe's *The Acts and Monuments Online*. Standard resources for this project are, of course, the *ESTC Online*, *EEBO-TCP*, and for later reprints of early modern sermons Internet Archive has become increasingly useful. A host of fine scholars have been drawn to the study of early modern sermons, but this field has lacked an annotated and comprehensive register of sermons and sermon events.

The developers of this project will use a TEI-compliant XML structure. Much of the platform can be encoded with standardized markups for such elements as date, speaker, and location. However, this project is faced with the task of identifying and defining elements for a register in a space between digital bibliography and online textual archives or corpora.

Metadata will have to be extended to include an abundant number of tags for such areas as theological debate (e.g. purgatory, Eucharist) and church practice (e.g. baptism, burial). An exhaustive list of meta-concepts peculiar to the religious attitudes and movements of the period will have to be constructed. Among the many examples, such meta-tags as "anti-theatre," "Anabaptist," and "recantation," will have to be identified, agreed upon, and listed.

In sum, the greatest challenge for this project is in developing a comprehensive taxonomy for its metadata. In the view of the project team, the best way to approach this challenge is to start small and to learn by doing. Phase 1 of this project, therefore, is to digitalize and annotate Millar Maclure's register of the sermons of Paul's Cross along with the supplement to this edition.

Paul's Cross, the outdoor preaching pulpit located on the northeast side of the St Paul's precinct in early modern London, will be treated as ground zero for the cataloguing of early modern sermons. Located in the commercial and cultural center of London, Paul's Cross was the most influential public site for preaching to large, non-elite audiences in England during tumultuous periods of religious reform. This one locale had an immeasurable impact on Christian practice and public opinion from the Henrican period until the years leading up to the Civil War.

As the project expands toward its goal of being a comprehensive annotated register for all early modern sermons, the TEI XML encoding and extensions will allow scaling to a much larger platform. During Phase 1 the metadata arrangement for developers will be clarified. Should problems or omissions arise, which they invariably do, the fix can be made before the project expands. Finally, given that TEI has become the standard for what will become a partner project, this encoding will be highly adaptable should it eventually be contributed to a digital archive repository or OAIS.

A Stylometric Study of Nicholas of Montiéramey's Authorship in Bernard of Clairvaux's *Sermones de Diversis*

Jeroen De Gussem
jedgusse.degussem@ugent.be
Universiteit Gent, Belgium

Case Study

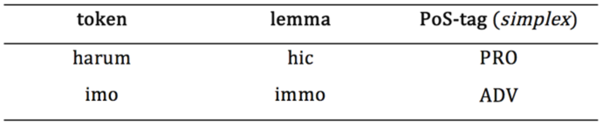
This short paper revisits the authorship of Bernard of Clairvaux's *Sermones de Diversis* (c. 1090 – 1153) through computational stylistics. Bernard's *De diversis* corpus comprises an assembly of unpolished and rudimentary sermons found in various, heterogeneous manuscripts. Bernard never disseminated the *De diversis* sermons himself, they have been first assembled, enumerated and published by Jean Mabillon in the 17th century (Callerot, 2006). Since Bernard of Clairvaux usually collaborated with secretaries, the obscure context of the corpus' composition and constitution has often made its sermons subject to some debate when it comes to Bernard's authorship. By 1145, the abbot's acclaim as the icon and figurehead of the Cistercian movement had brought along such a considerable administrative workload that the assistance of a group of secretaries was indispensable. These secretaries acted as Bernard's stand-ins, and spared him the time and effort it would cost of having to take up the quill himself at every single occasion. The *reportatio*, as it was called, entailed that the contents of Bernard's letters or sermons were engraved on wax tablets in a tachygraphic fashion. The cues, keywords and biblical references which Bernard had spoken aloud provided a framework that captured the gist of his diction. Afterwards, the scribe reconstructed what he had heard to a text on parchment which could pass for Bernard of Clairvaux's in its literary allure (Rassow, 1913; Leclercq, (2)1962; Constable, 1972). Amongst these amanuenses, Nicholas of Montiéramey († 1176 / 78) was as a focal figure, and a highly skilled imitator of his master's writing style. The influence of Nicholas' mediation on several particular text instances within Bernard's *De diversis*, and more generally on his entire oeuvre, has fallen subject to much debate.

Nicholas began serving Bernard as an emissary around 1138-41, carrying letters concerning Abelard's heresy to Rome (Turcan-Verkerk 2015). His literary qualities, likely to have been acquired through his education in the Benedictine abbey of Montiéramey, enabled him to immediately enter the scriptorium and officially become Bernard's closest secretary. Their friendship, however, knew an abrupt and painful ending in the final years of Bernard's life, around 1151-2, when Nicholas must have severely breached his master's trust by sending out letters without his permission. The scandal has for a long time upheld Nicholas' portrayal as a disreputable Judas by Bernard's side, a condemnation which has shimmered through on a scholarly level as well, and has resulted in highly subjective and speculative attributions. For instance, Nicholas has been found sending out Bernard's *De diversis* 6, 7, 21, 62, 83, 100 and 104 in a letter to count Henry the Liberal, claiming that they were "of [his] invention, of [his] style, aside from what was taken from others in a few places" (Leclercq, (1)1962). Also *De diversis* 40, 41 and 42 have been found within Nicholas' oeuvre (Rochais, 1962). Nevertheless, Nicholas' reputation as a fraud and a plagiarist has withheld 20th-century scholars such as Leclercq and Rochais to believe that his claim to authorship is any sense warranted, and has maintained the sermons' authenticity as uncontested, even despite the fact that later scholars have seriously doubted their views on Nicholas of Montiéramey's alleged deceitfulness and falsification (Jaeger, 1980; Constable, 1996). The temptation for historians to draw lines in between imitation and plagiarism in order to categorize writings and collate them in attributed editions, valuable as it is, can also be rather anachronistic or even unbefitting in a medieval context (Nichols, 1990; Cerquiglini, 1999). Perhaps Nicholas felt himself to be a rightful partaker in the composition of these works, a participation which might disclose itself stylistically.

Stylometry

The texts of Bernard of Clairvaux are edited in the *Sancti Bernardi Opera* (SBO), Jean Leclercq's edition published in 8 volumes. Nicholas' letters and sermons, on the other hand, still lack a modern edition, and can only be found in Migne's Patrologia Latina (see table 4). Although experiments and debates as to which textual features best capture stylistic difference are still ongoing, many state-of-the-art studies employ function words, which still prove to be the most robust discriminators for writing styles (Burrows, 2002). Function words are usually short and insignificant words that pass unnoticed, such as pronouns, auxiliary verbs, articles, conjunctions and particles, whose main advantage is their frequent occurrence, less conscious use by authors and content- or genre-independent character. Their benefit and success for stylometry in Latin prose have been convincingly demonstrated before, although the methodology still raises acute questions which keep stylometrists on the lookout for alternatives.

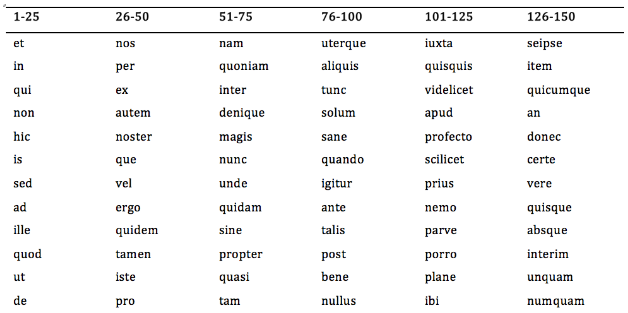
Because medieval Latin is a synthetic language with a high degree of inflection, the texts required some preprocessing (Mantello and Rigg, 1996). For instance, enclitica such as *-que* and *-ve* had to be separated from the token in order to be recognized as a feature. Secondly, texts are more easily mined for information when the lexemes are lemmatized (which means that the instance of the word is referred to its headword) and when its words (tokens) are classified according to grammatical categories (parts of speech). For this purpose we applied the Pandora lemmatizer-tagger on the texts, a piece of software developed by Kestemont and De Gussem that is equipped to achieve specifically this (Kestemont and De Gussem, forthcoming).



token	lemma	PoS-tag (*simplex*)
harum	hic	PRO
imo	immo	ADV

Figure 1. Excerpt from table showing tags applied to the texts

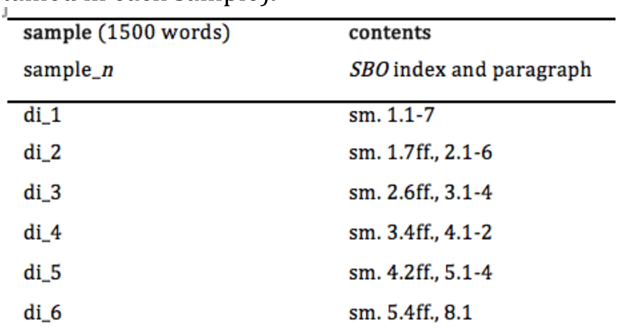
The third column, the part-of-speech-tag (PoS), allowed to immediately restrict the culling of most frequent words to those word categories that make up the collection of function words: conjunctions (CON), prepositions (AP), pronouns (PRO) and adverbs (ADV). This likewise filtered out some noise caused by ambiguities or homonyms like *secundum*. Once procedures of this sort were carried out in full, we arrived at a list of the 150 most frequent function words (MFFW) of the corpus (Figure 2)



1-25	26-50	51-75	76-100	101-125	126-150
et	nos	nam	uterque	iuxta	seipse
in	per	quoniam	aliquis	quisquis	item
qui	ex	inter	tunc	videlicet	quicumque
non	autem	denique	solum	apud	an
hic	noster	magis	sane	profecto	donec
is	que	nunc	quando	scilicet	certe
sed	vel	unde	igitur	prius	vere
ad	ergo	quidam	ante	nemo	quisque
ille	quidem	sine	talis	parve	absque
quod	tamen	propter	post	porro	interim
ut	iste	quasi	bene	plane	unquam
de	pro	tam	nullus	ibi	numquam

Figure 2. Excerpt from contents of a table showing most frequently occurring function words.

Each of the corpora was segmented into samples. This yields the advantage of "effectively [assessing] the internal stylistic coherence of works," (Eder et al., 2016) which answers directly to the primary goal of the present study. The sermons were segmented into 1500 word-samples (Figures 3-4 present aexcerpts from tables describing the texts contained in each sample).



sample (1500 words) sample_*n*	contents *SBO* index and paragraph
di_1	sm. 1.1-7
di_2	sm. 1.7ff., 2.1-6
di_3	sm. 2.6ff., 3.1-4
di_4	sm. 3.4ff., 4.1-2
di_5	sm. 4.2ff., 5.1-4
di_6	sm. 5.4ff., 8.1

Figure 3. Excerpt from a table describing the sample contents (1500 words) for Bernard's Sermones de Diversis as shown in figures 5-7.

sample (1500 words) sample_*n*	contents *PL* (vol: col.)
ep_1	ep. 1 (196: 1593a-1594b)
	ep. 2 (196: 1594b-1596a)
	ep. 3 (196: 1596b-1597b)
ep_2	ep. 4 (196: 1597b-1598c)
	ep. 5 (196: 1598d-1600a)
	ep. 6 (196: 1600b-1601b)

Figure 4. Excerpt from a table describing the sample contents (1500 words) for Nicholas' sermons and letters as shown in figures 5-7.

It should be noted that 1500 word-samples run the risk of increased imprecision, a consideration which should nuance any interpretation of the results (Kestemont et al., 2013). Once the corpus was divided, each of the text samples was vectorized to document vectors. The raw counts were TF-IDF-normalized (*Term frequency inverse document frequency*), a procedure which divides the function word frequencies by the amount of text samples that respective function word appears in (Manning, 2008; Kestemont et al., 2016). As a consequence, less common function words received a higher weight which prevents them from sinking away (and losing statistical significance) in between very common function words. Once the data was preprocessed and regulated, two statistical techniques were applied to visualize its dynamics.

The first is a *k* Nearest Neighbors network in GEPHI (hereafter abbreviated to *k*-NN) (Jockers, 2013; Eder, 2015; Jacomy et al., 2014), the second is principal components analysis (hereafter PCA) (Binongo et al., 1999). Their respective results will prove to be similar in a general sense, yet crucially different in the details. We argue that such an additional statistical validation provides for a more accurate, nuanced interpretation and a better intuition of the data. In the first visualization, the k-NN networks, we first calculated the 5 closest text samples to each text sample by applying k-NN on the frequency vectors. Accordingly for each text the 5 most similar or closest texts were calculated, weighted in rank of smallest pairwise distance (Minkowski metric, a Eucledian metric) and consequently mapped in space through force-directed graph drawing (algorithm Force Atlas 2). The weights were directly calculated from the distances. The intuition is then that the distances should be normalized to a (1,0) range (as a higher distance responds to a lower weight). Secondly, PCA is a technique that allows to reduce a multivariate or multidimensional dataset of many features, such as our function word frequencies, to merely 2 or 3 principal components which disregard inconsequential information or noise in the dataset and reveal its important dynamics. The assumption is that the main principal components, our axes in the plot, point in the direction of the most significant change in our data, so that clustering and outliers become clearly visible. Each word in our feature vector is assigned a weighting or loading, which reflects whether or not a word correlates highly with a PC and therefore gains importance as a discriminator in writing style. In a plot, the loadings or function words which overlap with the clustered texts of a particular author are the preferred function words of that author (see Figure 7 under "Results").

Results

Figure 5 (*k*-NN) and Figure 6 (PCA) feature the results of matching up Bernard's *Sermones de Diversis* benchmarked against the latter's *Sermones Super Cantica Canticorum* (his literary masterpiece) and the sermons and letters of his secretary Nicholas of Montiéramey.

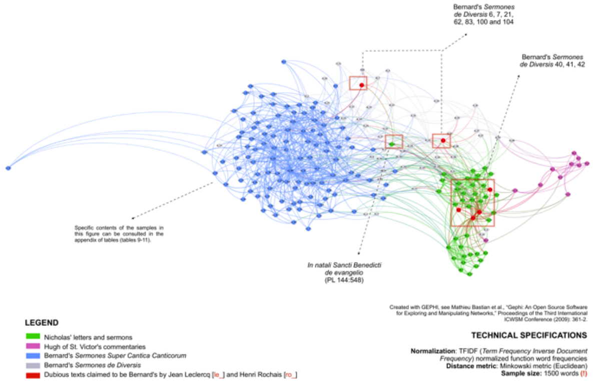


Figure 5: k-NN Networks

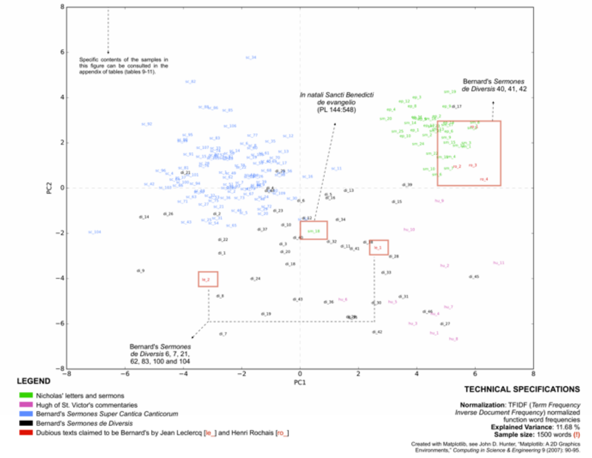

Figure 6. Principal Components Analysis (PCA)

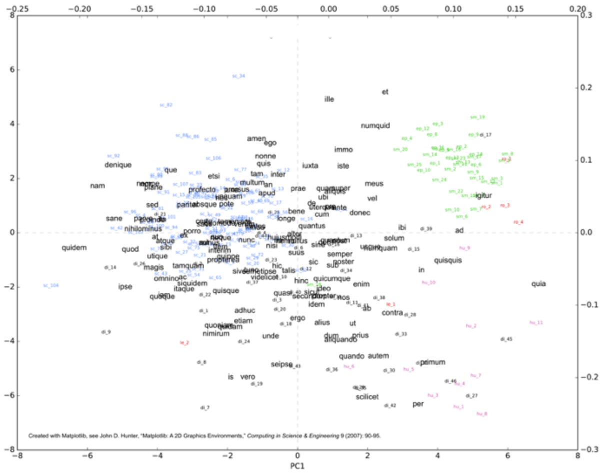

Created with Matplotlib, see John D. Hunter, "Matplotlib: A 2D Graphics Environments," *Computing in Science & Engineering* 9 (2007): 90-95.

Figure 7. PCA Loadings

Firstly, when examining the visualizations, it is striking how – indeed – the diversity of Bernard's *De diversis* is captured. Especially PCA demonstrates the discernible stylistic incoherence as the samples burst open all over the plot (especially along the vertical axis of the second principal component), at times suggesting the interference of other writers than Nicholas or Bernard in their composition. Other samples gravitate in between Nicholas and Bernard, and in some cases Nicholas' influence on the style is undeniable. *De diversis* 6, 7, 21, 62, 83, 100 and 104, which Nicholas included in the letter to count Henry the Liberal (they are split up in two red samples labeled with le_ of Leclercq), do not betray an obvious affinity to Nicholas' style (although le_1 is not far off). Neither are they unambiguously Bernard's. Both samples diverge strongly and seem too hybrid in nature to be restrained. The case rather ostensifies how difficult it is to defend concepts such as "single authorship" or "text theft" in a medieval context: the le_ samples are clearly not of a "singular" style (nor of Nicholas's style, nor of Bernard's), but defy classification. In fact, if we compare both *k*-NN and PCA, Nicholas' influence in sample le_1 seems considerably larger than Bernard's. It has by now become an untenable simplification to argue that Nicholas has stolen these sermons, especially if we review the results of the second case, that of *De diversis* 40, 41 and 42 (four red samples labeled with ro_ of Rochais): although the sermons emanate from bernardian thought, PCA and *k*-NN unambiguously cluster all three sermons together with those written by Nicholas, not Bernard.

Introduction

We present in this paper work consisting in porting to an integrated ontology two central resources for the classification of folktales: The "Motif-index of folk-literature" (Thompson, 1977) and the "Types of International Folktales" (Uther, 2004). The first resource, often called Thompson Motif Index (abbreviated as TMI) is available as an online resource. The second resource is a classification system for folktale types, which was published by Hans-Jörg Uther (2004), extending former work by Antti Aarne (1961) and Stith Thompson (1977). In the following we are using the acronym ATU for referring to this classification system. Recently, a large amount of the ATU data has been made available online, offering also annotation facilities for tales in multilingual versions.

Our work consisted in extracting from those resources, which are stored in different formats, classification relevant information and re-organizing them in two interrelated ontologies, using for this the W3C standards OWL (which stands for "Web Ontology Language" , RDF(s)– see the W3C recommendations for more details– and RDF. The aim is to make those classification resources machine readable, interoperable and to support by this formal representation of the metadata access to folktales annotated by those classification systems in the context of the Linked Open Data framework.

Thompson Motif Index

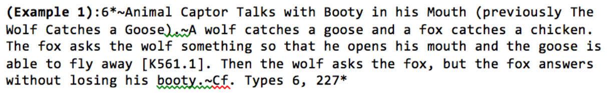
A folktale motif can be defined as a "repeated story element, e.g., a character, an object, an action, or an event that can be found in several stories". In TMI motifs are organized in a tree structure, providing for a parent-child relation between the listed elements. One motif entry consists of a motif-id and a motif name. Optionally, a **motif description** and **references** are provided. Table 1 provides for an example of few motifs illustrating the tree structure and hierarchy of TMI.

Motif-id	Motif name
A	Mythological motifs
A1	Identity of creator
A1.1	Sun-god as creator
A1.2	Grandfather as creator
A1.3	Stone-woman as creator
A1.4	Brahma as creator
A2	Multiple creators

Table 1: A few motifs from Motif-index of folk-literature and their hierarchical organisation

Aarne-Thompson-Uther Folktales Types (ATU)

A folktale type can be described as a main story line that can be found in several cultures. The parts of this story line can refer to specific story elements also known as motifs. A folktale type is therefore a bigger unit than a motif. As can be seen in example 1, an entry in the ATU system consists of a type id ("6*"), a title ("Animal Captor Talks with Booty in his Mouth (previously The Wolf Catches a Goose).") and a text summarizing the typical "storyline" of this type of folktale. Within or at the end of this "script", links to corresponding Thompson Motif-Indices can be provided ("[K561.1]"). Finally (and optionally), similar or related types can be indicated.

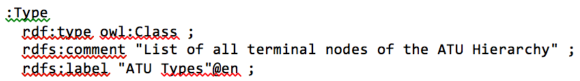


```
(Example 1):6*~Animal Captor Talks with Booty in his Mouth (previously The
Wolf Catches a Goose).~A wolf catches a goose and a fox catches a chicken.
The fox asks the wolf something so that he opens his mouth and the goose is
able to fly away [K561.1]. Then the wolf asks the fox, but the fox answers
without losing his booty.~Cf. Types 6, 227*
```

Generation of the Ontology

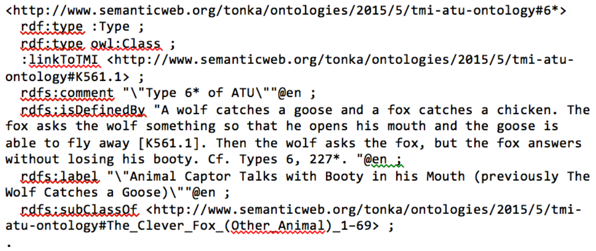
The OWL and RDF(s) representation for the ontology was generated semi-automatically from the html code of both TMI and ATU, responding to few design decisions we had to take. For TMI we went for a double representation: the hierarchy structure of the IDs is represented as an OWL subclass hierarchy, but all terminal nodes (leaves of the tree) are represented as both an instance of a class we call "Motif" and as an instance of the pre-terminal node in the taxonomy. This reflects our intuition that what Thompson called a motif is in most of the cases the content of the terminal nodes of the classification system, while the non-terminal nodes are more to be considered as abstraction helping in the taxonomic structures.

We compared the automatically created ATU part of the ontology to the printed version of Hans-Jörg Uther's "The Types of International Folktales". Using the ontology editor "Protégé", we manually added missing subclasses and individuals, rearranged generated classes and corrected errors such as typos in the electronic version of ATU or splitting errors because of inconsistent punctuation. By this step we obtained 2802 ATU classes organized in seven main subclasses, which have also subclasses, in accordance with the hierarchical structure of types proposed in (Uther, 2004). Below we display examples of the encoding of ATU data in our ontology. We first show a main class (we use the Turtle syntax for serializing the RDF code) of our ATU model ":Type":



```
:Type
  rdf:type owl:Class ;
  rdfs:comment "List of all terminal nodes of the ATU Hierarchy" ;
  rdfs:label "ATU Types"@en ;
```

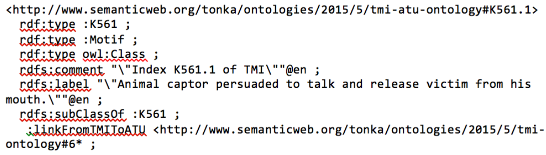
A subclass of "Type", for example the type "6*", has the following syntax:



```
<http://www.semanticweb.org/tonka/ontologies/2015/5/tmi-atu-ontology#6*>
  rdf:type :Type ;
  rdf:type owl:Class ;
  :linkToTMI <http://www.semanticweb.org/tonka/ontologies/2015/5/tmi-atu-
ontology#K561.1> ;
  rdfs:comment "\"Type 6* of ATU\""@en ;
  rdfs:isDefinedBy "A wolf catches a goose and a fox catches a chicken. The
fox asks the wolf something so that he opens his mouth and the goose is
able to fly away [K561.1]. Then the wolf asks the fox, but the fox answers
without losing his booty. Cf. Types 6, 227*. "@en ;
  rdfs:label "\"Animal Captor Talks with Booty in his Mouth (previously The
Wolf Catches a Goose)\""@en ;
  rdfs:subClassOf <http://www.semanticweb.org/tonka/ontologies/2015/5/tmi-
atu-ontology#The_Clever_Fox_(Other_Animal)_1-69> ;
.
```

In this example, the reader can see how the type 6* is linked to a motif occurring typically in its storyline: we introduced for this a property called "linkToTMI". Additionally, the subclass relation is expressed, using the rdfs:subClassOf property. The "rdfs:label" property stores the original short title of the ATU type in English ("@en"). We encode the original description of the type as a value to the property "rdfs:isDefinedBy". A main aspect of the ontologisation of ATU (and TMI) is that each folktale type (or motif) is now represented by a Unique Resource Identifier (URI), and thus accessible in the Linked Data framework, once our data set has been published in its cloud.

An example of a motif ("K561.1") is given just below. We focused for the time being only on motif-ids and names. This current limitation is due to the inconsistent format of the motif descriptions and references used in the html code of the online resource, which made it difficult to be automatically extracted. We will include this information in a next version of the ontology. As pointed out earlier, elements of the TMI are encoded in a dual fashion: as belonging to the class "Motif" but also to its immediate non-terminal node (here "K561"). The rdfs annotation property "rdfs:label" is used for encoding the name of the motif (here in English, marked by "@en"). Multilingual correspondences can also be included as values of this property.



```
<http://www.semanticweb.org/tonka/ontologies/2015/5/tmi-atu-ontology#K561.1>
  rdf:type :K561 ;
  rdf:type :Motif ;
  rdf:type owl:Class ;
  rdfs:comment "\"Index K561.1 of TMI\""@en ;
  rdfs:label "\"Animal captor persuaded to talk and release victim from his
mouth.\""@en ;
  rdfs:subClassOf :K561 ;
   :linkFromTMIToATU <http://www.semanticweb.org/tonka/ontologies/2015/5/tmi-atu-
ontology#6* ;
```

In this example, we also see the property "linkFromTMIToATU", which is the inverse property of the one pointing between ATU elements and motifs. Additionally, we have introduced a third "linking" property, called "linkFromAaThToATU", which ensures that types of former versions of ATU are linked to the new names in the final version of ATU. By this final step of expanding our TMI-ATU ontology we ended up with the number of 14,937 classes and the number of 49,752 individuals that are interconnected by 3 object properties: "linkFromTMIToATU", "linkToTMI" and "linkFromAaThToATU". We managed thus to convert two valuable, handcrafted resources of literary knowledge consisting of more than 4000 pages into a 15.4 MB in size ontology file that can be easily accessed and searched.

Conclusions

We presented our work on the ontology generation for two widely used folktale classification systems. This ontology can be visualised and processed by standard OWL tools such as Protégé. The integrated ontology will be made openly available soon, after last quality controls. Current work is on adding as instances of the ontologies URLs of folktales that are marked with the corresponding numbers and so to allow access to those via Linked Data mechanisms.

Modeling Place in *Ulysses*: Ontologies and Pre-texts

Caleb Derven
caleb.derven@ul.ie
Maynooth University, Ireland

John Keating
john.keating@nuim.ie
Maynooth University, Ireland

Introduction

What role does place, if any, figure in the digital scholarly edition? Gunn and Hart offer a prescriptive view of the role of place in Joyce's *Ulysses*: "The topography of Dublin is "on the page" at least as much as are the meanings of the words "priest," "kidney," and ineluctable modality": it is a part of the book's primary reference system, without which its full sense cannot be apprehended" (Gunn et al. 2004). Such a positivistic view grants a key role to place and suggests that the novel may be modeled, to some extent, along geospatial lines. This paper proposes a model for foregrounding geographical elements, within a digital scholarly edition, for *Ulysses*.

However, rather than supporting the naturalistic view that *Ulysses* constitutes a sort of textual analogue to geographic representations of Dublin, previous work has suggested that *Ulysses* complicates this perspective (Bulson 2011). In this context Pierre Joris' formulation about the US poet Ronald Johnson, "He also knew that to make history you have to disfigure geography" might be applied equally to Joyce and the example of *Ulysses* (Joris 2009).

While significant work has been done to date outlining the extracting of geographical elements from texts and using the resulting toponyms in GIS contexts (Gregory and Hardie 2011, Cooper et al. 2015), this paper considers the question of toponyms in literary texts in both the context of modeling and the role of source texts in the representation of place. The key element of this research is making explicit the connections between source text and novel and how these connections are reflected in external ontologies.

Eide (2014) asserts that maps, texts and landscapes all constitute different ways of modelling and different ways of experiencing place. Texts have the characteristic of being "underspecified": e.g. a text might designate a place as "east" as opposed to exposing coordinates on a map. Maps and texts work to create the condition of intermediality - a combined geocommunication system. Are there source texts, relative to *Ulysses*, that amplify this sense of intermediality? Do these texts, in conjunction with the novel, occupy a sort of liminal category between text and map?

Methodology

This approach extends earlier work using TEI in effectively modelling geographical elements in one episode of the novel and incorporates alternative models such as ontologies and RDF XML documents in augmenting TEI XML (Derven et al. 2012). Such an approach serves to instantiate Gabler's claim for the digital scholarly edition as a "web of discourses" (Gabler 2010). The paper also considers whether this approach can be generalised beyond the specific use case of geographic named entities in the text and considers whether the combination of TEI XML, external ontologies and paratextual data stored in RDF triples may be more widely extended to digital scholarly editions. The approach taken in the paper extracts named entities from the text, identify toponyms and incorporates them as geo-rectified elements in an encoding of the novel. A sample of two episodes encoded in TEI XML is used. However, the approach to modelling taken extends beyond that offered by a strictly TEI-based approach by using a semantic web based approach and links placenames in the text to ontologies (for example, geoNames). The paper weighs marking up place names directly in the encoding itself against linking to external ontologies.

This paper also considers an interface for digital scholarly editions that accommodates multiple versions, displays geographic data extracted from the text and utilises an ontology to model and encode geographical elements within the text. The interface is used to interrogate a single episode from Joyce's *Ulysses*, a text that can be avowedly positioned within a geographic context. The tenth episode of the novel, Wandering Rocks, both foregrounds and privileges geographic elements in such a way that place itself takes on a narrative function. The use of place too alters slightly from manuscript to fair copy through to printed editions. The paper foregrounds the methodologies and tools used in assembling the interface. Toponyms are extracted, modelled in terms of both possible sources used in the construction of the text and existing ontologies, and presented as part of the interface for the digital scholarly edition through a GIS service. The interface includes a map that plots changes in the use of place name in the construction of the text.

Conclusions

In the context of a novel where place and place names function as narrative markers, investigating geographical elements in a computational context becomes another way to both read through the novel and assist in establishing a critical editing function. For example, considering the digital scholarly edition as interface, it becomes interesting to track such changes not only from the perspective of the critical edition but also in terms of GIS. How does the role and use of placenames change in the developing text? Is there evidence for paratextual or secondary sources in the development of place as this role changes? What is the most appropriate way to model and refer to place in the text? The paper, then, models episodes in *Ulysses* along these three dimensions: as a digital scholarly edition, as a mapping network, and through an ontology for modeling geographic elements.

Automatically Analyzing Recordings of Musical Performances

Johanna Devaney
devaney.12@osu.edu
Ohio State University, United States of America

The Automatic Music Performance Analysis and Comparison Toolkit (AMPACT) is a suite of software tools for quantitatively analyzing musical performances for which a corresponding musical score is available. The primary target audience is music scholars who are interested in studying musical performance but who do not have the specialist technical skill or time required to develop their own tools. This toolkit enables music scholars to empirically, and automatically, analyze recorded performances, allowing scholars to study not just contemporary performance practices, but also the performance practices used in historical recordings. Empirical methods for analyzing musical scores have become increasing popular with the development of software such as Humdrum (Huron 1995) and music21 (Cuthbert and Ariza 2010), and the examination of recorded performance is a growing area of interest that shows similar potential (Cook 2014). AMPACT is particularly useful for musicologists and ethnomusicologists who are interested in undertaking longitudinal studies of music performances. Such studies may focus on large-scale differences in performances, such as the inclusion of additional notes, which is easy to detect by ear and annotate by hand. In contrast, they may focus the smaller scale, expressive aspects, of performances, such as variations in timing, dynamics, tuning, and timbre. The latter requires either careful, and extremely time consuming, manual analysis of visual representations of the audio sign or automatic analysis tools. Possible topics for smaller-scale studies include the development of a single performer's practice over time or changes in a particular performance style across time or geographical distance For general audiences in the humanities, the results of this type of longitudinal music performance research can be linked to other historical and/or geographic research in order to contextualize the similarities or differences observed across musical performances.

Researchers have studied recorded performances almost as long as recordable media has been available. Some of the most extensive work was undertaken by the psychologist Carl Seashore (1936, 1938) and colleagues at the University of Iowa also analyzed performances by pianists, violinists, and singers, employing a number of methods to study recorded performances. They studied piano performances from piano rolls and films of the hammers during the performance and violin and singing performances with a stroboscope, for frequency estimation, and an oscillograph, for intensity estimation. Accurate performance

data could be collected with these methods but the extraction of the data required a lot of work on the part of the researchers. As such, Seashore and his colleagues were only able to analyze a limited the number of pieces.

Interest in this type of detailed empirical analysis of recorded performances subsequently waned, likely due to the need for specialized equipment and the amount of time required for accurate analysis. Interest was revived in the late 1970s, as psychologists became intereste din studying musical rhythm, particularly in piano performance (see Palmer (1997) and Gabrielsson (1999, 2003)). The piano was popular because of its percussive nature and the ability to acquire measurements directly from the instrument—although this limited studies to performance made on specialized equipment. In contrast, the ability to extract performance data from recordings facilitates the study of existing recordings on a wider range of instruments.

There currently exist tools for accurately estimating tuning, and dynamics information for monophonic recordings once the locations of each note have been manually (e.g., PRAAT (Boersma 1993; Boersma 2001)) or automatically (e.g., Sonic Visualiser (Cannam et al. 2006) and TONY (Mauch et al. 2015)) annotated. For polyphonic audio (where there is more than one instrument playing), aligning the audio with a musical score can facilitate both the estimation of note locations and guide the subsequent estimation of tuning, dynamics, and timbre information for each note.

AMPACT is a suite of software tools uses score-guided methods estimate timing, tuning, dynamics, and timbre parameters for both monophonic and polyphonic audio. The technology implemented in AMPACT includes a score-audio alignment algorithm that is able to estimate timing asynchronies between notes which are written in simultaneities in the score (Devaney 2014), an important feature not only for studying differences in timing between performers but also for accurately guiding algorithms for estimating other performance parameters. The current version of AMPACT provides frame-level analysis of a number of tuning, dynamics, and timbre-related measurements for monophonic music and for tuning and dynamics for polyphonic music (Devaney and Mandel 2016). From these low-level measurements, high-level, perceptually informed, descriptors are calculated that summarize the low-level measurements over each note. Both the high-level descriptors and the low-level data can be stored in a special performance extension to the MEI encoding formats, so that the data can be released both for validating claims made in published research and for proving the data for other researchers to use.

In addition to describing AMPACT and its capabilities, this paper will also demonstrate the utility of AMPACT for digital musicology with a case study: a longitudinal study of the song "This land is your land" by Woodie Guthrie, a song that is notable for both its political and populist character. The case study explores systematic variations in the performance of the text "This land was made for you and me" within the performances (when the line retutns at the end of most verses) as well as across performers and performance contexts. Looking specifically at whether singers emphasize the words in different ways in live political contexts versus studio recordings. The performances include live and studio recordings by Woodie Guthrie, Pete Seeger, and Peter, Paul, and Mary, as well as more contemporary performers such as Wilco. AMPACT is used to automatically extract performance parameters (timing, dynamics, tuning) and compare the performance data within each recording and within each each performer's set of live and recordings to see how much variation occurs within songs, within singers' performances, and across performance contexts (e.g., studio, concert, and protest recordings).

Leveraging Expert Domain Knowledge to Learn a Representation of Symbolic Music

Johanna Devaney
devaney.12@osu.edu
Ohio State University, United States of America

Music manuscripts offer as much potential as text manuscripts for data mining and, as with resources like Google Books, there is a wealth of data available online. Currently the largest resource, the International Music Score Library Project (IMSLP), has more than 370,000 scores in its database. While many of these scores exist only in image-based formats, ongoing improvements in the area of Optical Music Recognition (OMR) allow for automatic conversion from images to symbolic representations, which include information such as instrumentation, key signature, time signature, and the notes' pitches, metrical positions, and durations. In order to exploit the research potential of these symbolic music databases, a representation that captures temporal relationships within the music is needed that highlights the structurally significant parts of the musical surface, while ignoring ornamentation.

This paper describes a representation that emphasizes the more structurally significant parts of the musical surface and de-emphasizes less significant parts, such as ornamentation, by integrating human domain expertise and data-driven approaches within a temporal machine learning model. The representation contains less information than the musical surface but more than corresponding chord labels, which discard information about musical texture and are too generalized to use for detailed similarity and classification tasks. The weighting for the various components of the musical surface is determined from an initial harmonic analysis. This harmonic analysis will be performed by a hierarchical model of chord labels and phrases, which will function like a "language model" in speech recognition. In music theory, phrase models describe musical phrases in terms of the tonic, predominant, and dominant functions (Laitz 2012). The inclusion of the expert domain knowledge expressed in the phrase function model helps to resolve the ambiguity between the musical surface and appropriate chord labels in the harmonic analysis, namely whether a particular chord is likely to occur in a particular part of a phrase. Taken in combination with OMR, this representation could be used to render searchable all available scanned music. These searches would not be limited to melody, as is the current state-of-the-art, but would also allow for querying by chord progressions and/or formal structures. The representation can also facilitate automatic hierarchical analysis of musical structures and provides a basis from which to undertake classifications and similarity tasks. Classification tasks include harmonic analysis or assessing the likelihood of a particular composer having composed a piece of unknown provenance, while similarity tasks include longitudinal studies over a composer's career or across composers.

Much of the work on analyzing the growing wealth of music data has been heavily influenced by text retrieval methods through their use of N-grams, sequences of N contiguous symbols. N-grams work well in modeling monophonic sequences, such as when directly applied to the musical surface for monophonic melody retrieval (Pickens, 2001) and for chord retrieval when the chords occur as distinct vertical units (Scholz et al., 2009). This has been demonstrated effectively on peachnote.com (Viro, 2011) with an N-gram viewer similar to the one Google makes available for Google Books. One significant area where N-grams have problems, however, is for more complex textures where the notes of chords are not played simultaneously, which is true of a large proportion of western art music since 1750. One way to address this problem is to automatically segment the musical surface into beat-length frames and treat the contents of each frame as a "chord" (Radicioni and Espositio, 2006), which is well suited to chorale textures but is problematic for arpeggiations or other textures where the chords notes don't occur simultaneously. Another approach is to analyze chord labels rather than the musical surface, such as the system of de Haas et. al (2011), although these are often not available.

The representation described in this paper takes a different approach, using a conditional random fields (CRFs) model for developing both a data-driven model, where all of the feature functions and potentials are learned from the data, and a hybrid data-driven/rule- driven approach, where domain knowledge "rules" are used to design feature and potential functions. Data for the purely data-driven approach comes from a domain expert-labeled dataset of Mozart and Beethoven piano works in theme and variation form (Devaney et al. 2015). The rule-driven approach incorporates the rules presented in textbooks used in undergraduate music theory curricula, primarily Laitz (2012). This hybrid data- and rule- driven approach is motivated by previous work that demonstrated that a combination of data- and rule-driven models performed better than either approach alone on music analysis tasks (Devaney and Shanahan 2013).

This paper will also discuss the implications of this use CRFs for analyzing other metrically structured cultural products, such as poetry or song lyrics, as well as how this approach could be generalized to other digital humanities projects, specifically for relatively "data- poor" problems where there is a large amount of domain expertise that can be modeled, such as the study of narrative in natural language. More broadly, this work presents a vision of the digital humanities, where large-scale data-driven approaches are balanced by deep domain knowledge and the types of humanistic questions being asked require the development of more sophisticated technology than is currently available.

L'extraction automatique des motifs dramaturgiques dans les séquences de deux scènes

Marc Douguet
marc.douguet@paris-sorbonne.fr
OBVIL, Université de Paris-Sorbonne, France

La structuration intrinsèque du texte théâtral en une suite de scènes réunissant chacune un nombre défini de personnages offre des potentialités infinies pour l'analyse quantitative. Ce domaine a déjà fait l'objet de nombreuses études, notamment dans la lignée des travaux de S. Marcus, qui montre qu'une pièce de théâtre peut être modélisée sous la forme d'une matrice binaire où chaque personnage est codé comme une suite de 0 et 1 selon qu'il est absent ou présent dans les scènes successives qui divisent le texte (Marcus 1973).

Jusqu'à présent, l'analyse des matrices dramatiques s'est notamment concentrée sur le nombre de scènes où apparaît un personnage, son nombre d'entrées, les différentes relations de coprésence qu'il entretient avec d'autres personnages, etc. (Marcus 1972; Lafon 1990; Ilsemann 1997) Ces paramètres permettent de qualifier de manière globale les personnages et l'intrigue en appliquant à la dramaturgie des outils empruntés à l'analyse statistique ou à l'analyse des réseaux. Cependant, selon cette approche, l'enchaînement des scènes et l'ordre dans lequel elles sont disposées ne sont pas pris en compte. Ils le sont en revanche dans les travaux de M. Dinu sur la stratégie des personnages, qui cherchent à calculer la probabilité de la réalisation d'une configuration de personnages donnée en fonction de celles qui la précèdent (Dinu 1984).

Nous voudrions ici présenter une nouvelle approche qui, comme celle M. Dinu, prend en compte la progression du texte, mais adopte le point de vue surplombant qui est celui du dramaturge au moment où il dresse le plan de sa pièce et s'intéresse avant tout aux techniques d'écriture dramatique. Nous introduisons pour cela la notion de *motif dramaturgique*, défini comme une séquence d'entrées et de sorties de personnages, abstraction faite de l'identité de ces derniers. Deux suite de scènes ne faisant intervenir aucun personnage commun ou appartenant à des pièces différentes peuvent donc instancier le même motif.

Prenons comme exemple la matrice dramatique de *Mélite* de Corneille :

Actes	I					II								III						IV										V					
Scènes	1	2	3	4	5	1	2	3	4	5	6	7	8	1	2	3	4	5	6	1	2	3	4	5	6	7	8	9	10	1	2	3	4	5	6
TIRCIS	1	1	1	0	1	0	0	0	1	0	0	1	1	**0**	**1**	**1**	**1**	**0**	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1
ERASTE	1	1	1	0	0	1	1	1	0	1	1	1	0	**0**	**0**	**0**	**0**	**0**	0	0	0	0	0	1	1	**0**	**1**	**1**	0	1	1	0	0	0	1
MÉLITE	0	1	0	0	0	0	1	0	0	0	0	1	1	**0**	**0**	**0**	**0**	**0**	0	1	1	1	1	0	0	**0**	**0**	**0**	0	0	0	0	1	1	1
CHLORIS	0	0	0	1	1	0	0	0	1	0	0	0	0	**0**	**0**	**0**	**1**	**1**	1	0	1	1	1	0	0	**0**	**0**	**0**	1	0	0	1	0	1	1
PHILANDRE	0	0	0	1	1	0	0	0	0	0	1	0	0	**1**	**1**	**0**	0	0	1	0	0	0	0	0	0	**1**	**1**	**0**	0	0	0	1	0	0	0
CLITON	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0	0	0	0	0	0	0	1	0	1	0	0	0	0	1	0	0	0	0	0
LA NOURRICE	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	1	0	0	0	0	0	0	1	1	0	0	0	1
LISIS	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0	1	0	0	0	0	0	0

Les scènes III, 1-3, III, 3-5 et IV, 7-9 instancient un même motif, représenté en gras, qui peut être exprimé sous la forme d'une sous-matrice

$$\begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \end{pmatrix}$$

ou sous la forme plus lisible d'une séquence codifiée de caractères où A désigne le personnage qui apparaît en premier, et B celui qui apparaît en second, les scènes étant délimitées par "/" et les personnages, à l'intérieur d'une scène, par "-" :

A/A-B/B

La comparaison de ce motif avec un autre motif de trois scènes et deux personnages permet de comprendre l'intérêt de cette méthode. Ce motif, que l'on rencontre dans *Mélite*, II, 1-3, est le suivant :

$$\begin{pmatrix} 1 & 1 & 1 \\ 0 & 1 & 0 \end{pmatrix}$$

soit

A/A-B/A

Notre hypothèse est qu'indépendamment de la longueur de chaque scène composant le motif et de la répartition de la parole entre les personnages, chaque motif présente toujours, dans la diversité de ses réalisations, des enjeux comparables. En l'occurrence, les deux motifs que nous venons de citer illustrent deux techniques de composition bien distinctes. Soit un personnage reste en permanence sur le plateau, soit le dramaturge renouvelle entièrement le personnel dramatique, profitant de la scène centrale pour faire se croiser les personnages qui se relaient sous les yeux des spectateurs. Dans le premier cas, un personnage sert de pivot à l'action, et en rencontre successivement plusieurs autres. Ce faisant, il guide l'attention du public. Dans le second, le point de vue du spectateur dépasse celui de l'ensemble des personnages : il en sait et en voit plus que chacun d'eux individuellement.

L'étude des motifs dramaturgiques devient encore plus intéressante quand on regroupe ensemble les personnages qui, à l'intérieur d'un motif, ont une distance scénique nulle

(Marcus, 1972), c'est-à-dire sont toujours présents et absents en même temps. Ainsi, *Mélite*, I, 1-3 repose sur le motif

$$\begin{pmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 0 & 1 & 0 \end{pmatrix}$$

Or malgré le fait qu'il y a deux personnages présents en permanence, et non un seul, ce motif n'est pas fondamentalement différent de

$$\begin{pmatrix} 1 & 1 & 1 \\ 0 & 1 & 0 \end{pmatrix}$$

Dans les deux cas, une confrontation centrale est entourée par deux scènes présentant un caractère plus "privé", qui permettent de comparer l'attitude d'un personnage ou groupe de personnages avant et après une rencontre avec un autre personnage ou groupe de personnages et de faire entendre le discours qu'ils tiennent en l'absence (et bien souvent au sujet) de ce dernier.

Méthodologiquement, cette approche est comparable à l'étude des motifs syntaxiques développée dans le cadre de la stylistique computationnelle (Boukhaled 2015), si ce n'est que chaque élément du motif se définit non par le choix unique d'une classe de mot, mais par le choix multiple d'un ensemble de personnages. Elle possède donc *a priori* les mêmes applications, notamment la qualification du style d'un auteur (entendu ici comme style de composition, et non comme style d'écriture, et dont l'unité de base n'est pas le mot, mais la scène).

Nous avons constitué une base de données comportant tous les motifs de moins de huit scènes extraits d'un corpus de plus de 200 pièces de théâtre françaises écrites entre 1630 et 1680. Le choix de cette période se justifie par son importance dans l'histoire du théâtre français, et par le renouvellement des techniques dramaturgiques qu'elle permet d'étudier (passage du théâtre "baroque" au théâtre "classique"). Pour interroger cette base, nous avons développé un moteur de recherche qui, pour un motif donné, renvoie sa fréquence d'apparition sur l'ensemble du corpus, son évolution, ainsi que sa répartition par genre et par auteur.

Il ne s'agira pas ici de présenter les détails techniques de ce travail, mais de livrer les premières conclusions auxquelles nous sommes parvenus. Une des pistes possibles pour exploiter cette base de données est d'étudier l'évolution et la répartition de l'ensemble des motifs possibles pour un nombre donné de personnages et un nombre donné de scènes. Pour cette première étude, nous nous intéresserons aux motifs composés de deux scènes. La combinatoire est facile à produire. Si l'on regroupe les personnages qui sont présents et absents en même temps, seuls trois personnages ou groupes de personnages peuvent intervenir (un quatrième personnage aurait nécessairement une distance scénique nulle avec un autre), et quatre motifs sont possibles:

A/A-B
A-B/A
A/B
A-B/A-C

On constate, dans notre corpus, la disparition progressive du motif A/B (aucun personnage commun entre deux scènes contiguës), qui s'explique par l'exigence croissante de continuité dramatique. Un autre phénomène est plus inattendu et n'a pas encore, à notre connaissance, été vraiment étudié : deux scènes sont plus souvent reliées par une entrée (A/A-B) que par une sortie (A-B/A). Autrement dit, les personnages ont tendance à entrer séparément, mais à sortir de manière groupée, ce que nous tenterons d'expliquer en convoquant la notion de "tension dramatique". Enfin, on constate une légère augmentation puis une légère baisse des entrées et des sorties simultanées (A-B/A-C), dont nous essaierons de rendre compte en mettant ce phénomène en corrélation avec l'apparition d'une technique d'enchaînement plus complexe reposant sur un tuilage des entrées et des sorties à l'échelle de trois scènes successives : pour relier deux dialogues différents, les dramaturges préfèrent de plus en plus intercaler une scène de transition à trois personnages (A-B/A-B-C/A-C) plutôt que faire entrer et sortir deux personnages en même temps sans que ceux-ci ne se parlent (A-B/A-C).

Ces considérations générales nous mèneront à étudier le détail de la répartition des quatre motifs par genre et par auteur. Enfin, nous distinguerons les scènes qui appartiennent au même acte et celles qui se situent de part et d'autre d'un entracte. Les entractes sont en effet rarement pris en compte dans l'analyse des matrices dramatiques, alors qu'ils jouent un rôle essentiel. Une des règles de la dramaturgie classique voudrait par exemple qu'un personnage présent à la fin d'un acte ne le soit pas au début du suivant (Aubignac 1657). Une étude statistique vérifie en partie cette règle, mais montre aussi qu'elle est très fréquemment enfreinte.

Toutes ces questions visent à définir une norme d'écriture (pour une époque, un genre, un auteur). Mais les outils numériques ne se limitent pas à l'analyse quantitative : ils enrichissent également l'analyse littéraire en permettant de découvrir à l'intérieur d'un vaste corpus des cas particuliers, qu'il serait quasiment impossible de repérer sans procéder à une extraction automatique. On se penchera ainsi sur les pièces où l'un des quatre motifs est sur- ou sous-représenté, en se demandant quels sont les enjeux de cette anomalie pour la conduite de l'action et l'effet produit sur le spectateur.

"Come Together, Right Now": Discovery and Interoperability for Born-Digital Music Scholarship

Timothy Charles Duguid
tim.duguid@glasgow.ac.uk
University of Glasgow, United Kingdom

Elizabeth Grumbach
egrumbac@tamu.edu
Texas A&M University, United States of America

Summary

Music scholars have unprecedented access to an ever-growing digital corpus of music-related content, as libraries and institutions continue to digitize their holdings at an extraordinary pace. Yet, access to and discovery of these resources is problematic for music scholars. In 2016, the Music Scholarship Online (MuSO) project was awarded a grant from the National Endowment for the Humanities, Office of Digital Humanities to begin forming a community of music scholars to address these issues. This short paper will present the results of the planning meeting and further work done to address the social and technical issues impeding the interoperability, discovery, and access of born-digital music scholarship.

Proposal

Music scholars have unprecedented access to an ever-growing digital corpus of music-related content, as libraries and institutions continue to digitize their holdings at an extraordinary pace. Of course, curators describe digital content in ways that best suit their collection's needs, using a variety of metadata standards such as MARC, Dublin Core, and LIDO (just to name a few). Despite the obvious benefits to such flexibility, interoperability between digital collections has proven difficult, forcing music scholars to navigate between several interfaces and platforms in order to locate research materials. More importantly, access to these resources is limited to scholars already aware of their existence.

Platforms such as the Digital Public Library of America (DPLA), Europeana, and HathiTrust are working to solve these issues by aggregating digital collections into single catalogues, therefore making collection holdings accessible and interoperable. These platforms and others like them are adept at aggregating a variety and breadth of content (including, for instance, audio recordings, encoded content, musical scores, photographs, manuscripts, and printed texts) relevant to a variety of disciplines. The structure of these aggregators are heavily reflective of the library collections that make up the bulk of their data. But, unlike the discrete digital collections themselves, these platforms bring together information about holdings and digitized materials from diverse institutions, borders, and economies in order to make them discoverable in new ways.

However, there is a host of content consistently left out of even the best and most extensive music catalogues and digital aggregators: born-digital scholarship. This new model for of scholarly knowledge production has motivated humanities scholars to consider how digital catalogs and collections should evaluate and make visible new forms of scholarship. When Jerome McGann introduces the DPLA in 2011's "On Creating a Usable Future," he locates our humanities crisis not only in the evaluation of digital scholarship, but also "the sustainability of born digital resources and the work they support" and forging paths to make new forms of scholarly knowledge production "a general institutional practice" (182). To make digital scholarship an institutional practice, we must consider not only our social infrastructures (promotion and tenure), but the technical infrastructures that allow discoverability and interoperability - two concepts that are crucial to making our work visible and accessible across audiences and publics. For digital scholarship in music, no aggregators, platforms, or institutional ventures currently ensure that born-digital scholarship is widely discoverable and therefore accessible.

Music Scholarship Online (MuSO) is a community of scholars dedicated to resolving these issues, thus providing greater access to born digital music scholarship. It began in 2015 as a Digital Humanities Start-up Grant funded by the National Endowment for the Humanities, in which music librarians, music encoders, and musicologists gathered to discuss issues surrounding aggregation and peer review for born-digital music scholarship. Participants in the planning meeting came together to ask and answer "What do music scholars need in a digital curator and search mechanism?" Ultimately the team chose to follow the model of the Networked Infrastructure for Nineteenth Century Electronic Scholarship (NINES) and the other members of Advanced Research Consortium (ARC). In 2016, MuSO officially joined ARC, a federation of virtual research environments that coordinates several thematic and period-specific aggregators, like MuSO, into a catalog "containing resources spanning the bulk of Western civilization, from the medieval period to the early 20th-century" (Grumbach and Mandell, 3).

This short paper describes the present metadata prototyping efforts of the Music Scholarship Online (MuSO) project. Arguing that it is unnecessary for digital project teams to generate preservation-quality metadata, this paper describes how MuSO is working with ARC to generate a metadata schema for discovery that is lightweight and therefore a better option for digital projects facing constrained budgets and limited timescales.

Beginning with a brief introduction to the unique challenges facing born-digital projects in music, the paper then presents the history of MuSO and its initial phase, in which the basic metadata guidelines and peer review processes were developed. Afterwards, the paper reports on current efforts to build a prototype schema for MuSO: a discovery-level metadata standard for digital projects in music. It shows how the MuSO and ARC leadership teams have worked together in examining present aggregators of music resources such as the the Digital Archive of the Beethoven-Haus, the Digital Image Archive for Medieval Music, and the Juilliard Manuscript Collection, as well as well-established catalogues such as *Répertoire Internationale des Sources Musicales* (RISM) and *Répertoire Internationale de Littérature Musicale* (RILM). It reveals the similarities and differences between the metadata standards of these resources, and then it identifies the most significant elements for discovery-level metadata.The paper then concludes by comparing these elements with those present in the musical holdings of multidisciplinary collections such as the DPLA, Europeana, and the HathiTrust to ensure that
MuSO's lightweight metadata schema accurately captures the level of description needed to work within the multidisciplinary ARC catalog.

If born-digital scholarship is to become general institutional practice, the methods of discovery for that scholarship must be familiar to all humanists: all of the multidisciplinary, multilingual and international scholars that our institutions serve. The authors will therefore present findings concluded from an examination of the current MuSO Metadata recommendations as decided by the MuSO community alongside existing multidisciplinary metadata schemas. By investigating the push and pull between discovery-level metadata and preservation-level metadata, this short paper reports our efforts to ensure that Music Scholarship Online effectively describes the born-digital scholarship it intends to aggregate.

How the notion of access guides the organization of a European research infrastructure: the example of DARIAH

Suzanne Dumouchel
suzanne.dumouchel@dariah.eu
DARIAH, France

DARIAH (Digital Research Infrastructure for the Arts and Humanities) is, as the name implies, an infrastructure dedicated to research in digital arts and humanities. Developed under the auspices of the European Commission, it aims to organize communities in those fields, to develop interdisciplinary projects, promoting in particular the digital dimension of humanities and arts research by disseminating good practices, and providing tools and services. In legal terms, it is what is called an ERIC, that is to say a European Research Infrastructure Consortium, which is composed of national members that have come together to promote common objectives and serve common communities. Several ERICs have been created since 2009 in Europe, mostly based on a disciplinary approach, membership by several European countries, and the pooling of services.

DARIAH had already a long existence as an unofficial structure since 2005, but it become fully established as an ERIC in 2014. It brings together 17 countries in Europe which makes it the biggest ERIC in terms of members, but it is also distinct because it serves a very wide community consisting of the whole of Arts and Humanities research. This breadth poses real questions regarding the notion of access. The role of all ERICs is to share tools. services, human resources, projects, software, etc. to enrich research. Doing so for a community as broad as DARIAH's creates particular challenges.

Through this presentation, we wish to give an account of the specificities of this infrastructure by presenting the issues related to the notion of access that contribute to the structuring of DARIAH. Many of our pre-existing understandings of how access impacts upon humanities and arts research date from the days of the library collection, and it is common to limit the notion of access to research data. But within the framework of a research infrastructure consortium, the notion of access is made more complex. We will evidence this different paradigm here with five examples, which we will develop in turn by explaining both the constraints and the solutions that are envisaged to solve the problems encountered.

According to the Cambridge Dictionary, "access" has two kinds of meanings: the first one concerns "the method or possibility of getting near a place or a person” and the second one “the right or opportunity to use or look at something”. Both meanings are interesting in terms of creating an expanded understanding of access in field of Digital Humanities. Even if we mostly think about the second one (open access, open data, and so on), the first one shows the necessity of being near our community and highlights the fact that thanks to digital tools we are nearer and nearer despite the distance and we are able to work together being in different places.

DARIAH positions itself to support an emerging research culture in ways that invoke both of these meanings, as the examples below illustrate.

Managing interdisciplinarity

When one addresses a community as broad as that encompassed by the expression "Arts and Humanities", itself vague regarding the disciplines that it covers, one implicitly raises the question of what access by these Communities to this hyper-infrastructure represented by DARIAH will mean.

This implies first and foremost the need to define, more or less precisely, what is meant by the expression "Arts and Humanities", and in particular the expression "Humanities", which varies across European languages and across places and times. For example, are the social sciences included or not? And on what grounds can you bring together researchers from communities as diverse as literature, history, philosophy, cinema studies and perhaps even geography and linguistics? To be useful, DARIAH needs to develop a common language with common services and tools which can be used by people in those different fields. In this case, access concerns the way DARIAH communicates with its communities and the projects it launches, to encourage interdisciplinarity without seeming intrusive. Indeed, this infrastructure has as one of its objectives to contribute to organizing a gigantic network of specialists in those fields. To do that, it is necessary to think about how to create such a network, to animate it and to make it last. Several initiatives are being developed, both thematic and national, which we will present as responses to this challenge.

Managing tensions between national and international perspectives

Access also has a political dimension. When the same tool is developed in parallel in two different countries, how can we know how to assign credit for the development? Which should be valued by DARIAH? There is thus a problem of selection, and therefore a possibility of bias, in the choice to favor promoting the access to one tool rather than another. To resolve this tension, the DARIAH community is coordinated around National Representatives who are engaged in complementary, rather than competitive, work. This work is based in particular on the dissemination of information about the activities of the national teams and the projects in which they are involved.

On the other hand, some teams may wish to retain the rights or control of their tools and may not wish to make them accessible to other communities without compensation. We will see how this constraint contributes in turn to the structuring of the DARIAH ERIC.

The question of access thus raises political and diplomatic problems that may interfere with more neutral criteria of quality of the tool, its durability, its usefulness.

Speaking to whom?

The role of DARIAH is also very broad insofar as this European consortium has an ancillary mission for the development of new communities. But this mandate is very vague. Do we mean fields of research? Specific countries? Or people inside? In this section, we would like to focus on people. Toward this end, DARIAH has specific functions in terms of teaching digital practices, not only within the current network but also beyond it, with the goal of opening and expanding it to encompass researchers (including under and postgraduate students) who may or may not have any competences in digital tools but who are interested in them. In this way DARIAH acts as a facilitator to help people to use digital tools and services.

One question that we must ask, however, is whether we can or should open our community to, for example, private companies, which would help in the development of tools and / or which would benefit, once again, from inclusion. The wider the access, the less control there is. And what would DARIAH mean and how would it act if the infrastructure became open to all without distinction of disciplines, places, people? Conversely, what would be its meaning, if by privileging shared access to knowledge and tools, it decided to close the door to some? Imperatives toward democratizing the benefits DARIAH can bring come at such junctures into conflict with the possibility that too much access could dilute the infrastructure’s effectiveness, distort its scale or divert its mission. Again, this is an aspect related to the question of access to which the infrastructure must respond and on which we shall give a few quick lines of reflection.

Managing tools

This point is particularly well recognised within the DH community, since it questions the interoperability of tools. For DARIAH, questions regarding managing access to tools arises in terms of languages, content, formats and, of course, sustainability. Within DARIAH, the issue of interoperability is paramount, to leverage our large scale, but also to enable disciplinary practices usage models; given that the research questions posed at the origin of these uses will vary so considerably.

Specific attention is therefore paid to this aspect and in particular to data hosting. One of the first tasks that DARIAH has set itself is to work on long-term data hosting. To do this, it has, for example, relied on national hosts able to also integrate data from multiple countries. These include the CNR in Italy (via the PARTHENOS project) and Huma-Num in France.

This perspective on access reflects as well the importance of the trust that must be established between the partner countries, in particular with regard to intellectual property, as suggested in the next and final point.

Building collaborative tools

DARIAH is an infrastructure that brings together 17 countries and a range of diverse disciplinary communities. In this sense, it involves collaborative work that relies mainly on the use of digital tools. But one problem remains: the too easy access to collaborative tools developed by companies that do not share the same conception of intellectual property and data security. Tools such as Google doc and Google drive, etc. are unavoidable in the context of collaboration between researchers, but the access in this case is so easy that their existence prevents the development of alternative tools that correspond more closely to the specificities of scientific exchanges. It is now important to develop virtual working environments conducive to scientific exchanges and the needs of researchers, particularly in the communities concerned.

To enhance its ability to navigate the many requirements of access, DARIAH has recently launched a far-reaching 3-year program of actions, which will be presented as well as an example of how a holistic approach to access can be manifested in an institutional strategy. By explaining how the document has been formulated and how community support for it has been developed, the presentation will give a worked example of how access can be negotiated across countries and disciplines.

The notion of access lies at the heart of the issues dealt with by infrastructures such as DARIAH, as they seek to structure and facilitate coordination and exchange of tools, and the development of research. Questions of access, which are too often reduced to the management of the data, imply each time a positioning; And that even when the stated objective is to be open to all, it is nonetheless subject to a form of choice.

Augmented dance scholarship: computer-assisted analysis of Javanese dance

Miguel Escobar Varela
m.escobar@nus.edu.sg
National University of Singapore, Singapore

Luis Carlos Hernández Barraza
a0107963@u.nus.edu
National University of Singapore, Singapore

This case study of Javanese dance argues that biomechanical analysis of dance can be used to augment dance scholarship: quantitative biomechanical data can complement rather than supplant other kinds of dance scholarship. In proposing this, we draw a parallel to the vision of computer assisted-literary criticism presented by Sinclair and Rockwell (2016), where interpretive textual analytics enable different readings of a text or corpus, rather than a quest for scientific truth. Similarly, we suggest that the visualization of biomechanical data enables other ways of looking at dance.

Our research project continues a long history of recording dance movements, but also departs from previous projects in important ways. Different notation systems, recording media and technological tools have been developed in order to capture the fleeting quality of dances. A few well-known examples include Eadweard Muybridge's photographic series depicting dance movements in the 19th century, the Labanotation system developed by Rudolf von Laban in the early 20th century and the application of biomechanics to study ballet in the 1970s, as exemplified by the papers in the conference *At the Dance: Verities, Values, Visions: Binational Dance Conference* in Waterloo, Ontario in 1971.

The practical applications of these systems and methods have been justified along several lines: the transmission of choreographies, dance pedagogy, description and classification of dance movements, and injury prevention. Initial enthusiasm for the scientific study of dance waned after the 1970s and has had little impact in mainstream dance scholarship. Recording of choreographies using Labanotation and motion-capture devices are still very common, but the quantitative analysis of the data obtained in this way is not.

In a parallel development, choreographers and dance collectives often use dance-tracking systems and visualizations as part of their work; notable examples of such practitioners include William Forsythe, Siohban Davis, Merce Cunningham, Anne Teresa De Keersmaeker and BADco. Unlike the quantitative studies of dance, these creative uses of dance data within performances are widely celebrated within dance scholarship and practice (Bleeker 2016). These playful uses of data and visualization are mostly constrained to creative dance practice. Even if they are often discussed within dance scholarship they are not often deployed as analytical approaches within dance scholarship. Our present study shows a way in which this could change.

Combining methods from dance ethnography and biomechanical engineering, we recorded differences in the building blocks of a well-known Javanese dance: *Sendratari Ramayana*. The *Sendratari* (often translated as ballet) is a modern Indonesian dance practice that combines movement gestures from royal dance traditions (*beksa* and *srimpi*), and from classical operatic dance-dramas (*wayang wong*) in order to present stories from the Ramayana (the Sanskrit epic that provides narrative background for many performance forms in South and Southeast Asia). We were interested in the "body types", a series of rules that describe how the main five types of characters should move: *luruh* (extremely refined), *lanyap* (vigorous-refined), *gagah* (vigorous), *raksasa* (ogres), *wanara* (simians), and *manuk* (birds). These rules define the rhythm and body angles at which the same movements (standing, walking, fighting, etc.) are performed by each character.

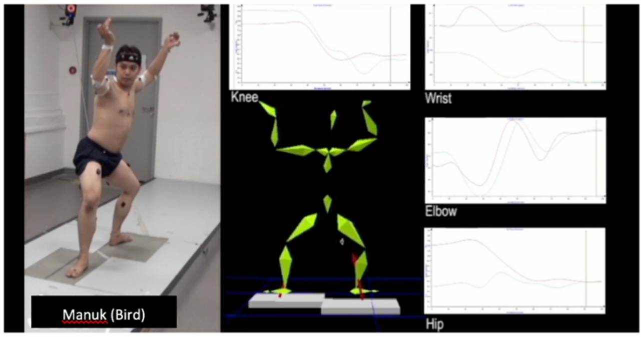

Figure 1. The dancer performs the standing motion corresponding to a bird. The movement can be seen as an animation of all major limbs and as graphs carting the movement of each joint through time.

For our study, we placed markers in all major joints of a professional dancer and we asked him to perform all basic movements as would befit each body type. Using the resulting data, we calculated the range of motion for each joint (difference between the maximum and the lowest angles). By comparing the ranges of motion pertaining to different body types, we discovered that the more subtle, elegant body types have the biggest range of motion. This is surprising even to experienced dance scholars. The demons and monkeys hold their arms in wider gestures and it would be easy to conclude that they have wider ranges of motion. The movement of the refined characters is slower and one can easily lose track of the fact that these movements actually require a greater range of motion. Indeed, similar assertions are absent in the literature. Our goal is to present our results through two interactive web displays:

- As a series of video panels, where a user can see a particular movement performed by a particular body type. Different videos can be displayed together: a recording of the dancer, an animation showing the position of the markers, and animated graphs that show the movement of specific joints (Fig. 1).
- Graphs that show a comparative overview of all movement types. For example, using Principal Component Analysis (a method often used in textual scholarship in the DH), we generated a comparison of the different body types (Fig. 2).

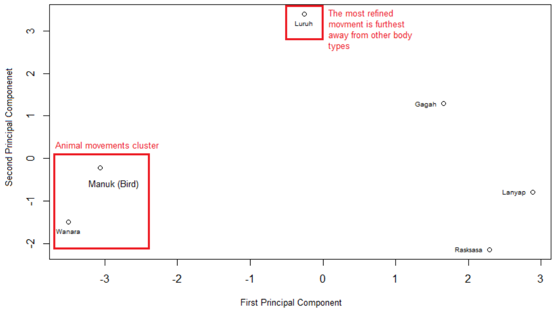

Figure 2. Principal Component Analysis of the ranges of motion of the main body types.

These results are not only aimed at a quantitative validation of scientific premises: their key contribution to dance scholarship is that they can help us look at dance differently. Borrowing a term from Sinclair and Rockwell, we describe our visualizations and graphs as hermeneutica, interpretive toys that can change how a scholar looks at a particular cultural practice (dance in our case, text in theirs). Like them, we see our results "not as microscopes revealing the inner structure, but as augmentations adding to a history of interpretation" (Sinclair and Rockwell 2016: 101). Rich, qualitative descriptions of "body types" across multiple Javanese art-forms (puppetry, dance and dance-dramas) are available in previous dance scholarship and in ethnographies of Java. Dancers and scholars have developed evocative metaphors to describe the qualities of movement.

Our study constitutes the first systematic measurement of the differences among "body types" in Javanese dance but its goal is not to disprove previous scholarship. Our main interest is to explore how visualizations of our research data can be used to help scholars look at dance differently. We suggest a way forward for dance scholarship where interactive displays allow multiple ways of understanding dance, at the crossroads of ethnography, dance criticism and quantitative biomechanical analysis.

Making Manuscripts Searchable: *DEx, a Database of Dramatic Extracts,* Digital Pub-lication, and Boutique Projects

Laura Estill
lestill@tamu.edu
Texas A&M University, United States of America

Too often, people lament that we have no evidence of what Shakespeare's readers thought. In reality, we have quite a bit of evidence, but it has been difficult to access because of the cost of travel and the barrier to access caused by early modern handwriting. This paper describes how *DEx: A Database of Dramatic Extracts* (beta version) contributes to the changing landscape of digital projects that help us better understand the early modern period. Rather than focusing on one person (too often, a canonical male literary figure), *DEx* instead makes a wide range of reader responses to early modern drama searchable, bringing together resources that are held in geographically distant archives, from Oxford's Bodleian Library to the Folger Shakespeare Library in Washington, D.C.

Dramatic extracts (those parts from plays that people copied into their notebooks) are important evidence because they tell what early modern audiences and readers took, literally and figuratively, from plays. Right now, this important evidence of reader response is difficult to access for multiple reasons: firstly, these extracts are often uncatalogued and therefore hard to locate. Secondly, they are dispersed across multiple archives and require travel funding to reach (see Ioppolo 2004). Finally, they are written in early handwriting, and so require paleographical training to read. This paper examines the ways in which *DEx*, a comparatively small project, links to existing resources and draws on community to ultimately provide people access to evidence of what Shakespeare's readers thought. (Spoiler: it turns out they thought about other playwrights more than Shakespeare in his lifetime!) *DEx* complements the Folger *Union First Line Index* and the *Catalogue of English Literary Manuscripts* by making the full text of dramatic extracts searchable and by not being constrained to selections written in verse (like the former) or by canonical authors (like the latter). *DEx* includes materials that are not catalogued in *CELM* or repository catalogues, and invites scholars to contribute relevant citations, transcriptions, or leads they have.

DEx's transcriptions are part of what makes it so valuable. Despite advances in OCR (Optical Character Recognition) technologies, there is no adequate program to automatically recognize handwritten text: particularly when it comes to historical documents written in scripts that we no longer use today, such as chancery hand or secretary hand. While digital paleography is an ongoing area of research, it tends to focus now on transcribing and describing texts by hand or on teaching paleography with digital tools (Stokes, 2014, 2015; Rehbein et al 2009, esp. 110-338; Fischer et al 2010; Hassner et al, 2013). Many digital projects that focus on early modern English texts are hand-transcribed and encoded: consider, for instance, the Folger Shakespeare Library's *Early Modern Manuscripts Online* and *Shakespeare's World*, *The Recipes Project* or *Bess of Hardwick's Letters.* Transcriptions in *DEx* are undertaken by a small community of scholars: this paper explains how our community currently works and the future collaborations we hope to undertake, as well as the possible avenues for extending the project after its forthcoming full launch.

In 2010, Paul Conway argued that "We are at the end of 'boutique' digital scanning projects for which the principal goal is ... extraordinary attention to the unique properties of each artifact" (76). This paper contends that with early modern manuscripts, "boutique" projects are one of the best ways forward. Compared to massive manuscript digitization projects like *British Literary Manuscripts Online*, *DEx* is a "boutique" project actually make texts searchable with transcription, which is always the result of paying attention to each manuscript as a "unique artifact." This paper discusses the challenges that come with curating a boutique project and the ultimate benefits of having a small site that emerges from a specific set of research questions.

Although small digitization or transcription projects can open up a vast field of research, they need to be findable and peer-reviewed in order to do so. I examine the obstacles to having *DEx* published by a traditional publisher, while questioning how to define publication for digital projects and the costs associated with creating and maintaining an open access site. Furthermore, I discuss how digital publishing must address the peer review needs of emerging scholars and provide an imprimatur and guarantee of quality for users. The final section of this paper discuss the role of Iter: Gateway to the Middle Ages and Renaissance and ReKN: Renaissance Knowledge Network in publication and peer review for *DEx: A Database of Dramatic Extracts*. This is an appropriate short paper for DH 2017 because it discusses a project that is in beta and active development, it engages the larger questions of how and why boutique digital projects can flourish and provide value to humanities scholarship, and it engages the theme of "Access/Accès" by focusing on collaboration, public-facing scholarship, and digital humanities publication. The paper focuses on a single case study: *DEx: A Database of Dramatic Extracts* and its community, which addresses a much-needed gap in scholarship by transcribing manuscripts that tell us what Shakespeare's audience and readers actually read.

Résumé

Le but du présent article est de présenter une approche dont l'objectif est de mettre en place une plateforme générique, permettant la conception collaborative et l'exploitation de modèles ontologiques des données particuliers. Ils ont la particularité d'être facilement extensibles et compatibles avec le Web des Données Ouvertes *(Linked Open Data ou LOD),* destinée à être utilisée dans le domaine des humanités numériques *(Digital Humanities ou DH).* La démarche a été appliquée dans un premier temps à un instrument particulier : conception ontologique d'un wiktionnaire sémantique multilingue, multiculturel et multidisciplinaire des sciences humaines et sociales (SHS) afin d'une part de vérifier sur un exemple concret les fonctionnalités de la plateforme, et d'autre part de l'améliorer afin d'en faciliter la déclinaison à d'autres outils particuliers. En somme, le projet veut concevoir une fabrique de données intelligentes pour les humanités numériques *(Smart data factory for digital humanities)*; où la création des données suit un processus « cyclique », en deux étapes qui consistent (a) à créer directement dans la plateforme, par les experts du domaine, des données respectant toutes les normes exigées ; (b) à exploiter les données créées dans (a), en tant que données « expertes » validées, pour produire intelligemment et automatiquement, à partir de l'open data, de nouvelles données compatibles.

Introduction & motivation

L'objectif de ce travail vise la mise en place d'une plateforme centralisée d'aide à la conception collaborative de modèles ontologiques extensibles des données, facilitant la création et l'intégration des données interprétées et non ambiguës, dites données intelligentes *(Smart data)* au service des humanités numériques. Les contenus doivent être crées et générés sous forme de données structurées, sémantiquement annotées et liées, suivant des schémas de description bien adaptés. Dans notre cas, cela consiste à mettre en place un méta-modèle permettant de générer des modèles d'ontologies, des ontologies multilingues, multiculturelles et multidisciplinaires du domaine des SHS et une base de connaissances partagée et reconnue par des communautés de chercheurs.

Notre travail a été motivé par la fait que :

- Il n'existe pas suffisamment de données intelligentes, automatiquement exploitables, en SHS, à l'échelle internationale reflétant l'état de la coopération scientifique et culturelle entre la France et d'autres pays dont les concepts et lexiques pourraient évoluer de manières indépendantes
- Il y a un grand déséquilibre, d'un point de vue de la disponibilité des ressources numériques, entre le Français et les langues d'autres pays notamment celles des pays du sud
- Les dictionnaires multilingues, peu nombreux, sont souvent les résultats d'élaborations unilatérales
- Les traducteurs existants, également peu nombreux, ne prennent pas en compte tous les aspects liés aux contextes des définitions
- Les corpus multilingues pouvant constituer des sources de données sont également rares

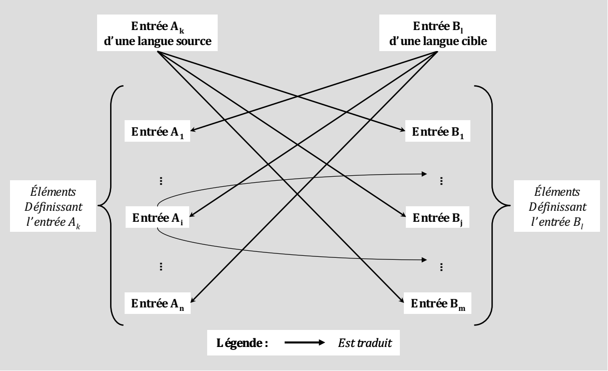
- Les travaux sur les nouvelles technologies et la normalisation des données des langues de certains pays sont encore à leurs débuts

Dans cet article, la présentation de notre approche, se fera à partir de la description d'une contribution à la construction ontologique d'un Wiktionnaire sémantique multilingue, multiculturel et multidisciplinaire des SHS. Cette dernière est basée, entre autres, sur une adaptation et sur une extension de la plateforme collaborative « Mediawiki sémantique » existante afin qu'elle puisse prendre en compte nos modèles ontologiques des données. Sa construction devrait permettre aux chercheurs d'échanger et de partager des connaissances dans le domaine des SHS et cela quelques soient leurs spécialités, leurs langues et leurs lieux géographiques de travail et/ou de résidence. Sa réalisation a intégré en plus, des normes et des protocoles bien spécifiques, en vue de son intégration dans le Web de Données Ouvertes (LOD).

Notre approche

Modèles des données

La conception de la structure de l'ontologie et donc du Wiktionnaire repose sur des correspondances entre les éléments de départ dans leurs contextes pour une langue source et les éléments d'arrivée dans leurs contextes pour une/des langue(s) cible(s) selon un sous-ensemble du schéma de la norme ISO1951. Pour simplifier, on va considérer les langues par paires. Donc, pour définir le modèle, on doit prendre en compte le fait qu'une entrée A_k dans une langue source peut avoir plusieurs sens et donc plusieurs traductions B_1, ..., B_j, ...B_m dans une langue cible. Cette même entrée A_k peut être définie avec plusieurs éléments A_1, ..., A_i, ...A_n du schéma du dictionnaire (cf. FIG. 2) qui peuvent êtres à leurs tour des entrées dans la même langue source et par conséquent, peuvent avoir plusieurs sens dans cette même langue source et plusieurs traductions dans la langue cible (FIG. 1). Notons que selon le sens de la traduction une langue source peut devenir cible et réciproquement.



Entrée A_k d'une langue source
Entrée B_l d'une langue cible
Entrée A_1
Entrée A_i
Entrée A_n
Entrée B_1
Entrée B_j
Entrée B_m
Éléments Définissant l'entrée A_k
Éléments Définissant l'entrée B_l
Légende : Est traduit

Figure 1. Extrait du schéma du dictionnaire des SHS

Ce schéma, récapitulant ce qui a été décrit précédemment, montre la complexité des renvois entre une langue source et une langue cible, ayant des spécificités différentes. Ce qui nécessite la définition d'un schéma spécifique dans chaque langue ainsi que la mise en place d'un système de gestion des correspondances d'une manière automatique. Nous pouvons procéder tout d'abord par une première simplification du problème de départ, qui consiste à associer à une entrée source (mot, locution, etc.) un ou plusieurs sens (définitions) qui renvoient à une ou plusieurs entrées cibles ; puis revenir du terme traduit, pris cette fois-ci comme entrée source. Ce procédé a été pris en charge par la mise en place d'un système de guidage d'aide à la génération et à la définition des correspondances entre les entrées, leurs définitions et leurs traductions dans les différentes langues. L'utilisateur peut modifier ou valider les suggestions du système pour compléter les fiches des entrées suivant les critères suivants (figure 2) :

- La définition d'une entrée se fait par la description d'une fiche suivant un format structuré déterminé par le schéma : contextes, définitions, relations sémantiques, traductions, indications grammaticales, parlers, etc.
- la signification attribuée à une entrée dépend d'un contexte de définition. Ce dernier est décrit par un ensemble fini et connu de paramètres contextuels des aspects: temporels, géographiques, disciplinaires, culturels, linguistiques, etc.
- Les relations entre les termes, se fait par le biais de relations sémantiques telles que : la synonymie, l'antonymie, l'hyperonymie, l'hyponymie, l'isonymie, la conversion, etc.

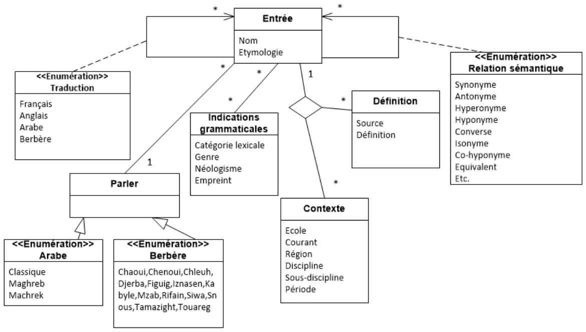


Figure 2.- Modèle du schéma du Wiktionnaire

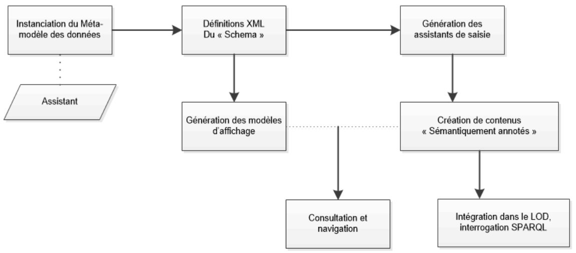
Plateforme

L'architecture mise en place pour la réalisation repose sur une conception générique, capable de prendre en charge plusieurs modèles de données « *schémas de données*» et plusieurs langues ; et reste flexible et facilement extensible à d'autres schémas et généralisable à d'autres langues. L'implémentation a été réalisée, suivant 4 modules fondamentaux, assurant la gestion de la totalité du workflow (figure 3).



Instanciation du Méta-modèle des données
Assistant
Définitions XML Du « Schema »
Génération des modèles d'affichage
Génération des assistants de saisie
Création de contenus « Sémantiquement annotés »
Consultation et navigation
Intégration dans le LOD, interrogation SPARQL

Modules du processus de l'application Wiktionnaire sémantique des SHS

Figure 3. Processus général

Le processus consiste en l'instanciation du méta-modèle des données et la génération des différents schémas d'utilisation. Cela se fait par des définitions XML (qu'on peut générer grâce à des assistants dédiés) permettant la génération des modèles des données, des assistants de saisies et d'annotations ainsi que des modèles d'affichage. Le processus intègre également des modules d'exploitation et d'intégration des données dans le LOD (import/export des triplets RDF), ainsi qu'module de consultation et de navigation (exposition d'un point de terminaison SPARQL).

Exploitation

Après les phases de tests et de validation des modèles implémentés, l'application est actuellement en production. Elle est alimentée par un réseau d'enseignants chercheurs répartis suivant les disciplines et les langues de leurs spécialités. Elle mobilise de plus en plus de chercheurs et comporte actuellement plusieurs entrées dans plusieurs langues et disciplines. Il est également important de noter que certains éléments du wiktionnaire ont été enrichis, grâce à des requêtes SPARQL bien paramétrées sur du LOD (comme DBpedia).

Conclusion

La plateforme permet, d'une part, de créer des contenus « Intelligents » directement dans la plateforme, d'autre part, d'utiliser les données créées pour les confronter avec des sources de données externes de l'Open Data et du Web de données (Linked open Data), pour générer de nouvelles données Intelligentes. La solution développée étant générique, son extension et son adaptation à d'autres domaines et à d'autres langues est une tâche facile. Une des perspectives de ce travail consiste à encourager la dynamique actuelle, afin que la plateforme puisse devenir une référence dans le domaine des ressources ontologiques et dictionnairiques au service des Humanités Numériques.

Introduction and related works

In recent years, the application of network analysis methods to literary texts has evolved into an independent research field of digital literary studies. Methods for the automated extraction of network data (named entity recognition, co-reference resolution) and their evaluation are of particular importance (Elson et al. 2010; Park et al. 2013; Agrarwal et al. 2013; Fischer et al. 2015; Waumans et al. 2015; Jannidis et al. 2016). Based on the data obtained, several types of analyses were developed: an empirical, quantitative and hierarchical description of literary characters (Jannidis et al. 2016), corpus-based analyses exploring options for historical periodisation of literature (Trilcke et al. 2015) and types of aesthetic modelling of social formations in and by literary texts (Stiller et al. 2003; Stiller & Hudson 2005; Trilcke et al. 2016).

What has been neglected so far (although already suggested by Moretti 2011) is the application of network analysis as a tool for quantitative plot analysis. In fact, current approaches in the field of literary network analysis are not suited to gaining insights into the plot development of literary texts (Prado et al. 2016). The sequential dimension of literary texts, as a consequence of their temporality, usually remains in the dark: what is extracted, visualised and analysed are *static* networks. Plot, however, is essentially a concept supposed to theoretically encompass the temporality of narrative (as well as dramatic) texts: "the repeated attempts to redefine parameters of plot reflect both the centrality and the complexity of the temporal dimension of narrative" (Dannenberg 2005: pp. 435). Plot can be understood as a concept for the description of the "progressive structuration" (Kukkonen 2013: §4) of literary texts.

Research objective: plot analysis

Attempts to further develop literary network analysis towards a quantitative plot analysis must consider the temporal dimension in the modelling of their research objects. The structure of a literary text is to be modelled as a changing sequence of network states. It is only through looking into these network dynamics that we can discuss network-analytic approaches for a quantitative plot analysis.

Following Prado et al. 2016, we are currently extending our research on literary networks (Trilcke 2013; Fischer et al. 2015ff.; Fischer et al. 2015; Trilcke et al. 2016) to the analysis of *progressive* structuration. Our goal is to examine whether (and with what kind of limitations) we can flesh out an operationalisation for the plot analysis of literary texts. By doing so, we are, of course, not trying to replace the semantically rich and versatile concept of 'plot' with a quantitative and thus reductionist concept. Rather, we will show that certain aspects of what is commonly discussed within the framework of plot analysis can be retraced by means of a computer-based analysis of network dynamics.

The visualisation of dynamic graphs, as is common in other domains (Pohl et al. 2008; Frederico et al. 2011), has recently been transferred to literary networks (Xanthos et al. 2016). While it may come in useful when close-reading a text and for didactic purposes, it is unsatisfactory when it comes to an actual corpus-based analysis. There are no canonical methods to help us compare network visualisations generated automatically by force-directed graph drawing algorithms. The reception of dynamic visualisations just does not offer practical analytical means. From a dedicated distant-reading kind of perspective, the calculation of dynamic network metrics and their statistical processing is much more promising as it offers options to describe general characteristics of networks from a larger corpus as well as to compare specific formal types of networks within the corpus.

Measuring dynamic literary networks

A number of basic global measures for the analysis of dynamic networks (i.e., size, density, homogeneity in the distribution of ties, rate of changes in nodes, rate of changes in ties) has been discussed by Carley (2003: pp. 135–36). In addition, Prado et al. 2016 recently suggested the application of actor-oriented measures, especially centrality indices, for the reconstruction of plot development. We are currently applying these measures to our own corpus, consisting of 465 German language plays. We also developed a set of other measures with recourse to traditional theoretical concepts for the description of specific phenomena of plot development, especially with regard to types of dramatic expositions (Pfister 1977: pp. 124–36), the "classical" act structure of tragedy and the composition principle of main and secondary plots (Pfister 1977: pp. 286–89). Calculation of these measures was implemented in our own network analysis tool *dramavis* (Kittel/Fischer 2017).

Event-based measures

In general, two types of measures can be distinguished for describing dramatic texts as dynamic networks: event-based and progression-based measures. Event-based measures are used to identify or characterise a particular point in time within a drama. In this context we developed an *all-in index*, a value that identifies the point in time at which all characters have occurred at least once in a drama (see Figure 1).

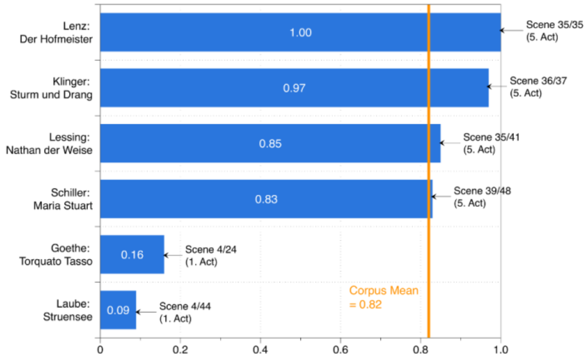

Figure 1: All-in index for 6 selected plays

The *final-scene-size* value characterises a specific point in time, in this case the last scene of a drama. It determines the percentage of all characters of a drama which appear on stage in the last scene. This value shows characteristic differences between dramatic subgenres, especially when comparing tragedies and comedies (see Figure 2).

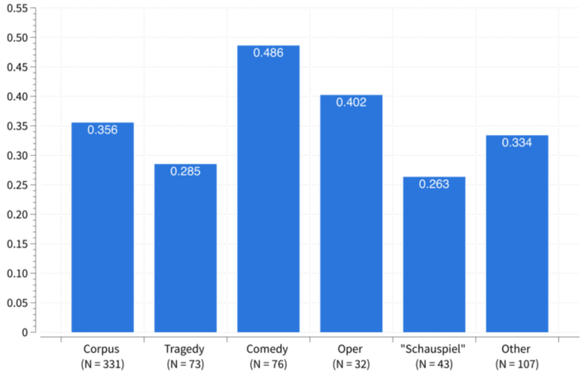

Figure 2: Final-scene-size index (mean values of entire corpus and subgenres)

Progression-based measures

While event-based measures allow assumptions about a particular state/point in time of the dynamic network, progression-based measures allow a general characterisation of the transformation of a dramatic network. In this regard, we introduced a measure we call the *drama-change rate*. The basis of our calculation is a modified Levenshtein distance, which only takes into account insertions ("add character") and deletions ("delete character"). In each case, we compare characters present in two consecutive scenes, eventually resulting in what we call the *segment-change rate* (Figure 3).

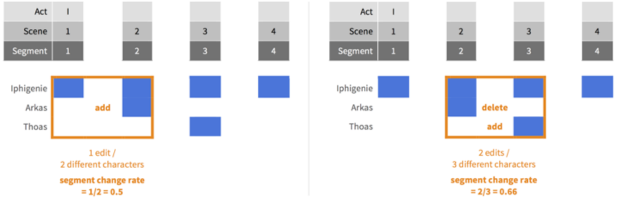

Figure 3: Calculation of the segment-change rate (example)

The sum of all *segment-change rates* of a drama divided by the number of all *segment-change rates* is what we call the *drama-change rate*. The development of this rate can be represented in a chart, which due to its shape we tentatively called the *beat chart* (Figure 4).

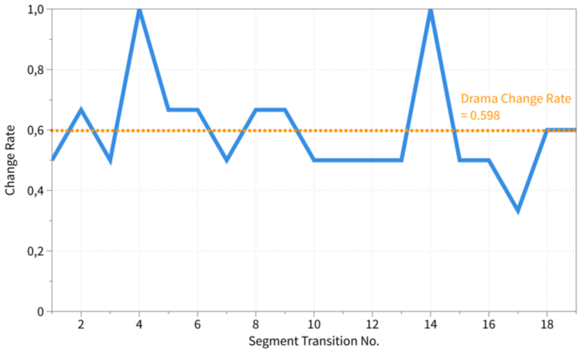

Figure 4: Beat chart for Goethe's play "Iphigenie auf Tauris" (1787)

Having calculated the *drama-change-rate* value for the entire corpus, we can start to compare a larger set of dramas with each other (Figure 5). It becomes evident that our corpus does not exhibit a clear trend along the timeline. Instead, we witness the emergence of characteristic types of dramas, which differ characteristically from the other texts in our corpus.

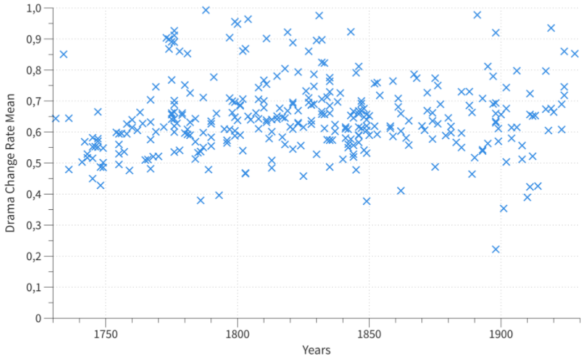

Figure 5: Historical distribution of drama-change rates in the DLINA corpus

On the one hand, we can identify dramas exhibiting a high *drama-change rate*, i.e., highly dynamic dramas with a constant alternation of characters on stage (Figure 6). On the other hand, low-dynamic dramas can be identified, with only small changes taking place between scenes (Figure 7).

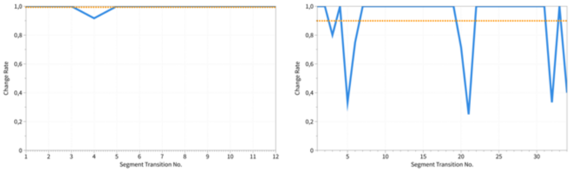

Figure 6: Two examples of highly dynamic dramas – left: Goethe's "Egmont" (1788); right: Lenz's "Der Hofmeister" (1774)

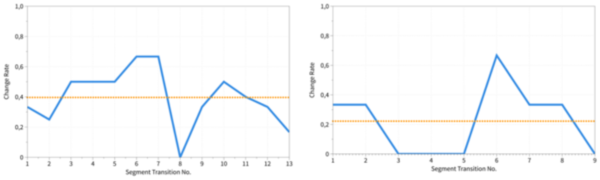

Figure 7: Two Examples for low-dynamic dramas – left: Goethe's "Der Bürgergeneral" (1793), right: Rilke's "Ohne Gegenwart" (1898)

A further option for the comparative analysis of our oscillatory *beat charts* is the analysis of the standard deviation of all *segment-change rates* of a drama. We can again distinguish two particularly striking types: On the one hand, there are dramas with a high standard deviation, indicating that extensive changes of characters alternate with small changes; we can call them high-dynamic dramas (Figure 8). On the other hand, there are dramas showing a low standard deviation, so the change on stage takes place in the same rhythm, we call these texts low-dynamic dramas (Figure 9).

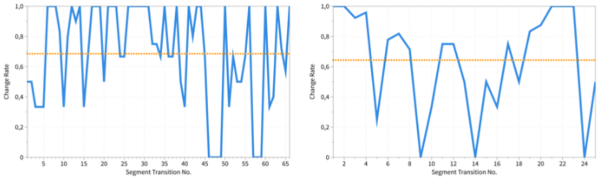

Figure 8: Two Examples for high-dynamic dramas – left: Benkowitz's "Die Jubelfeier der Hölle" (1801), right: Goethe's "Faust I" (1808)

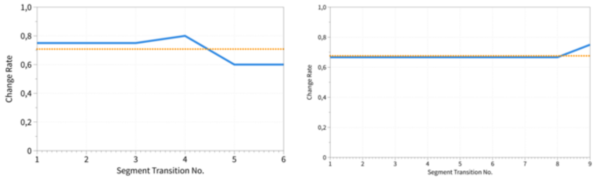

Figure 9: Two Examples for low-dynamic dramas – left: Schnitzler's "Anatol" (1893), right: Schnitzler's "Der Reigen" (1902)

The preceding cases each describe characteristic deviations regarding the *drama-change rate* of groups of texts. In addition, a 'normal type' of drama can be identified, which corresponds to the mean value for the corpus both in terms of arithmetic mean and standard deviation (Figure 10).

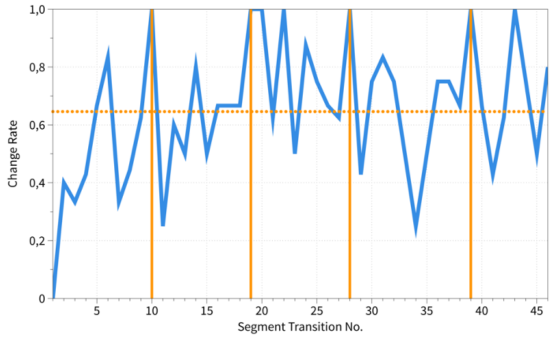

Figure 10: Beat chart for Ganghofer's "Der Herrgottschnitzer von Ammergau" (1880)

It also appears that strong upward shifts, accompanied by a complete exchange of characters on stage, often coincide with act boundaries (vertical orange lines), which is in accordance with historical conventions of dramatic composition.

Summary and further research

Our research on dynamic networks provides basic components for a quantitative analysis of the progressive structuration of dramatic texts. Future research will have to develop and evaluate additional measures and it will be decisive to hold interpretations of these measures against the backdrop of historical drama poetics.

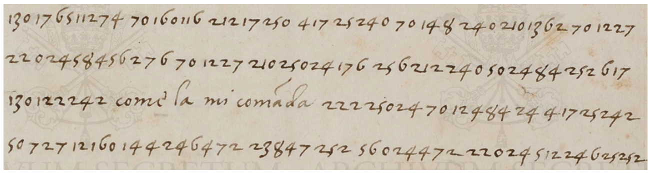
Introduction

Historical hand-written manuscripts are an important source of information for our cultural heritage, and automatic processing of these can help exploring their content faster and easier.

A special type of hand-written manuscripts that are relatively common in archives and libraries are encrypted, secret documents, so called ciphers. Ciphers may contain and hide important information for the history of science, religion or diplomacy and therefore shall be decrypted and made accessible. The automatic decryption of historical hand-written ciphers is the main focus of the project *DECODE: Automatic decoding of historical manuscripts.* In order to reveal the content of these secret messages, we collect and digitize ciphertexts and keys from Early Modern times, build a database, and develop software tools for (semi-)automatic decryption by cross-disciplinary research involving computer science, language technology, linguistics and philology.

Ciphers use a secret method of writing, often by transposition or substitution of characters, special symbols, already existing alphabets, digits, or a mixture of these. The encoded sequences are usually meticulously written and often segmented character by character to avoid any kind of ambiguity for the receiver to be able to decode the content, but continuous writing of some sequences where the symbols are connected also exists. In addition, the cipher sequences might be embedded in cleartext, i.e. texts in a known natural language, as illustrated in the picture below (Archivio Segreto Vaticano, 2016).



13017 6511274 7016 0116 2121 7250 417 25240 70 148 240 2101362 701227

13012 2242 comé la mi comada 22225024 70124 84 24 417 25242
50 727 12160 1442 46472 23847 252 5602447 2 22024 51224 625252

The first step for deciphering and making accessible the secret writing is their digitization and transcription. Transcription can be performed either by hand where a person types in the encrypted text symbol by symbol, or by (semi-)automatic means with a possible post editing by manual validation. Manual transcription is time-consuming and expensive, and prone to errors. Automatic methods applied to ease the transcription process are preferable. However, image processing techniques developed so far for historical text manuscripts, such as the ones from the project *TransScriptorium*, are not fully adequate for dealing with encrypted documents for several reasons. First, the transcribing system cannot benefit from any lexicon or language model because the key is, a priori, unknown. Consequently, the use of an optical model alone is prone to errors, especially when there are ambiguities in the shape of digits/characters. Second, many ciphers contain a mixture of plaintext and encrypted text (ciphertext), which requires specifically adapted handwriting recognition methods. Third, the arcane nature of the symbols used calling for semiotic analysis, which requires the study of techniques closer to hand-drawn symbol recognition rather than handwriting recognition ones.

In this paper, we study the feasibility of the current image processing techniques in order to digitize ciphers by recognizing and transferring the symbols into a computer-readable format. For this purpose, we present a semi-automatic transcription method based on Deep Neural Networks, followed by a manual validation. We compare the results with a complete manual transcription, and analyze the human time effort of the two scenarios.

Image Processing Methodology

The handwriting recognition system has the following steps: First, each document has been binarized, deskewed, and the text lines have been segmented using projection profiles. The images of the text lines are the input of the Multi-Dimensional Long Short-Term Memory Blocks Neural Networks (MD-LSTMs) (Graves and Schmidhuber, 2008; Voigtlaender and Doetsch, 2016). Contrary to previous techniques applied for recognition (e.g. HMMs), MD-LSTMs obtain good results without the need of computing feature vectors from the image.

For each text line, the output of the network is a sequence of digits. The system also detects when a digit has a dot above or below. Whenever the confidence of the system when transcribing a certain digit is low, the symbol "?" is used. This denotes that an expert user must check it.

In this work, the networks were trained using 15 cipher pages from six different ciphers (with six different handwritings) in order to learn the handwriting style variability. For validation set, we used 5 cipher pages from the same ciphers as in the training set but different pages. It must be noted that the amount of training pages is not enough for the transcription of cleartext, so all text words appearing in the document are denoted as "x". The transcription must be performed by an expert.

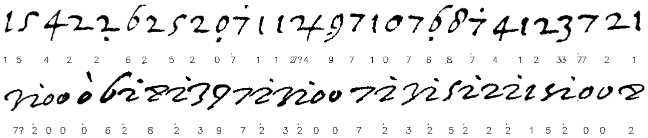
Finally, and with the aim of improving the visualization of the results and facilitating the posterior validation and correction task, we used force alignment between the result of the neural network and the input image.

Manual vs. Automatic Transcription and Correction

For the tests, we chose 14 new unseen cipher pages, of which 12 pages were taken from four ciphers in the training set, and two pages came from two new, previously unseen ciphers, which means that these handwriting styles have not been learned during training. In this way, we can also analyze the generalization and scalability degree of the method for new handwriting styles.

To compare the speed of automatic versus manual transcription in a fair way, each manuscript was manually transcribed by one person, whereas the output from the automatic transcription was corrected and validated by a different person.

In the manual transcription, the transcriber opened the image of the cipher, and transcribed it symbol by symbol in a text file. Contrary, for validation, the transcriber opened the output from the automatic transcription as a picture where the cipher page was segmented line by line and the suggested transcription was reproduced below. As it can be observed in the figures below, the symbol "?" appears when the system is not confident on the transcribed digit. Also, if the system detects a dot above the digit, then the transcription also contains the dot.



The results obtained by manual transcription and validated transcription from automatic output were compared and shown in Table 1. In average, the automatic system transcribes the digits with an average accuracy of 88 %. However, one of the ciphers (Francia_18_3_233r), written by a writer whose handwriting was not represented in the training set, was more difficult to the system to automatically transcribe and accuracy decreased to 61%.

Cipher	No. of lines per page	Manual (mins)	Validation (mins)	Accuracy automatic	Manual mins/line	Validation mins/line
Francia_4_1_221r	3	5	4	92%	1.67	1.33

Spagna_423_9_491v	21	25	20	93%	1.19	0.95
Average	**17.43**	**23.43**	**21.6**	**88%**	**1.39**	**1.17**

Table 1. Summary of results per line and cipher given the time in minutes for manual transcription, as well as the validation and correction of automatic transcription; the accuracy of automatic transcription, and the average rate of manual transcription and validation per line. Rows in red color denote those where the manual transcription is faster.

The results show that in most cases manual transcription is 15% slower on average compared to the automatic transcription with post-editing if the accuracy of the image processing is above 90%. When accuracy is lower, validation time usually increases because the more transcription errors we find, the more effort it takes to localize both the wrong symbol(s) in the picture and in the transcription file. For each error, the user usually starts to read the line from the beginning.

It is also noteworthy that we do not count the time it takes to prepare and train the automatic transcription models, including the preprocessing of the images (cut the margins, clean the bleed through, etc.) and the time for training the models. We also noted that the validators would have benefited from a user-friendly transcription tool where transcription suggested by the model was aligned with the original symbol in the picture. However, the automatic transcription clearly helped to differentiate between two different symbols written similarly, thereby helping the user to identify the symbol set represented in the cipher.

Conclusion

We have shown that image processing can be used as base for transcription followed by a post-processing step with user validation and correction. Even though image processing techniques need to be trained today on individual handwritings to reach high(er) accuracy, they might be of great help to identify the symbol set represented in the manuscript and to make clear distinctions between symbols, hence can be used as a support tool for the transcriber.

In this work, we focused on ciphers without any esoteric or other symbol sets, which might be more difficult for an automatic recognition system. Also, we have identified only cipher sequences; cleartext was only detected without any further transcription.

In the future, we would like to test combining image processing and automatic decryption in one step to skip the time-consuming transcription step and create synergy effects as both image processing and automatic decryption tools rely on language models that could be used simultaneously. Another alternative is image processing for validation of the manual transcription, which might be an interesting alternative to investigate in the future.

Introduction

In the mid-1850s, American educator and editor Elizabeth Peabody (1804-1894) set off from Boston to ride the rails. She traveled as far north as Rochester, NY; as far west as Louisville, KY; and as far south as Richmond, VA, in order to promote the textbook she had recently published, *A Chronological History of the United States* (1856). Along with her suitcase, Peabody traveled with a large fabric roll, which, when unrolled, displayed a grid-like array of colored squares that represented the major events in U.S. history. In the nineteenth-century version of a product demo, Peabody would arrange the “painted centuries,” as she called them, on the floor, and invite potential textbook adopters to sit around the charts and contemplate the colors and patterns that they perceived (9).

Although not described in terms of visualization--the term did not enter common parlance until the early twentieth century--Peabody’s ideas about the uses of her charts anticipate many of the benefits associated with visualization today: the ability to “offload” mental processing “from cognitive to perceptual systems,” to “enhance” pattern recognition through “abstraction and aggregation,” and, crucially, to interact with and potentially “manipulate” the visualization itself (Card et al. 1999, 16). For Peabody did not only imagine that her readers would interpret the “data” presented on her charts; she also intended for them to create charts of their own. To this end, Peabody also sold workbooks of blank charts, so that students could read each chapter of her textbook, and then convert the list of events that followed into color and position, according to her visual scheme.

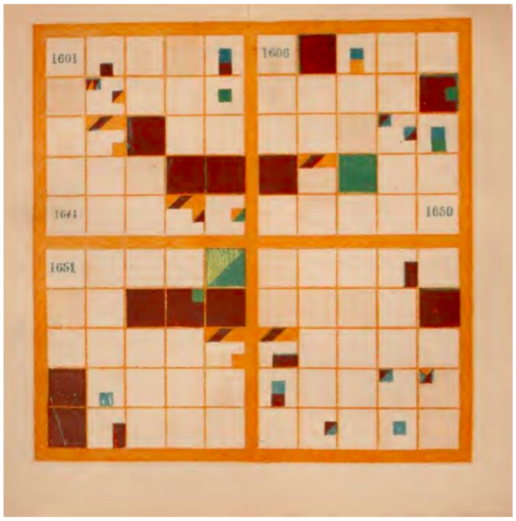

Figure 1: Peabody’s visualization of the significant events of the seventeenth century. In *A Chronological History of the United States, arranged with plates on Bem’s principle* (New York: Sheldon, Blakeman, 1856).

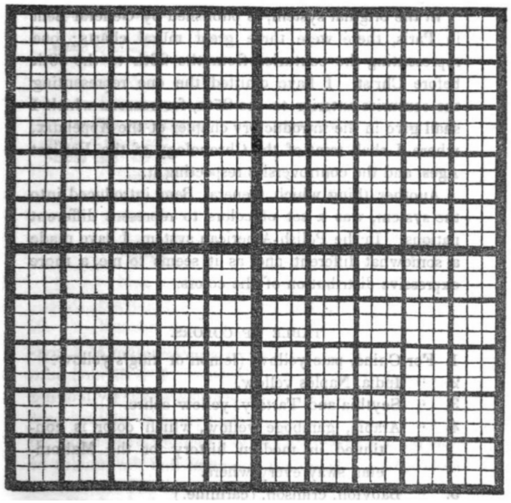

Figure 2: A blank chart included in The Polish-American System of Chronology: Reproduced, with some modifications, from General Bem’s Franco-Polish method (New York: G.P. Putnam, 1850).

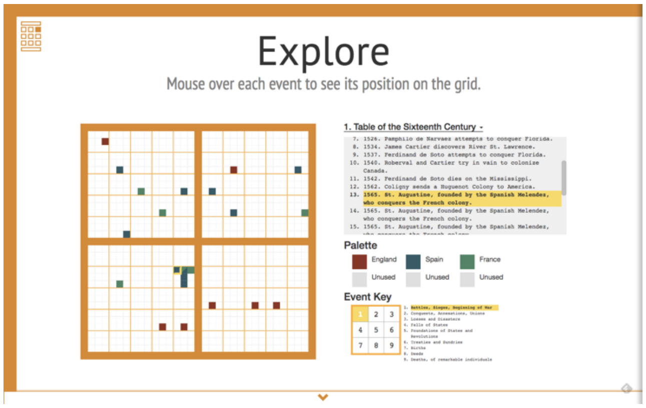
Project Overview

Drawing from recent digital humanities work relating to historical fabrication (e.g. Elliott et al. 2012, Sayers 2015), as well as from our own previous explorations of historical visualization techniques (e.g. Foster et al. 2016), we set out to recreate and enhance Peabody’s pioneering visual design. In particular, we focused on Peabody’s ideas about interaction and interpretation, since her ideas about the tripartite relation between data, text, and image-- and the role of the reader in translating between each-- speak directly to current debates in the digital humanities about the importance of acknowledging data as “capta” (Drucker 2011), and of recognizing the role of individual interpretation in both the design and reception of visualizations (Posner 2016). In our project, we focused first on reimagining Peabody’s original interaction for the web, employing current information visualization research to suggest techniques for emphasizing the interrelation between the data and their visual display. We then began a project to recreate the floor-sized version of Peabody’s chart using physical computing materials, so as to further explore the embodied aspects of Peabody’s visualization scheme. In the following sections, we describe the design choices involved in each recreation-- the digital and the physical-- with particular attention to how we sought to amplify Peabody’s ideas about interaction, interpretation, and embodiment through our reimagined interfaces.

The Shape of History: Reimagining Interaction and Interpretation for the Web

The Shape of History website represents the culmination of a year-long iterative design process. From Peabody’s original textbook, we distilled four conceptual modes of interaction: an “explore” mode, designed to explain to novice users how to interpret her charts, and how to translate between text and image; a “lesson” mode, designed to allow users to create their own charts, drawing upon Peabody’s original data; a “compare” mode, designed to call attention to how choices in visual display affect the charts’ ultimate interpretation; and a “play” mode, intended to facilitate the most open-ended form of interaction and expression. To implement the site, we employed a combination of HTML5, CSS, and JavaScript, including Bootstrap.js for site structure, jQuery for navigation and site-level interaction, and D3.js and two.js (along with custom JavaScript) for the visualization components.

At each juncture, we considered how to enhance Peabody’s original designs and interactions. For instance, when recreating the grid that would serve as the primary typographical form, we remained faithful to the original design and color palette, while adding additional minor grid lines (in light gray) so that users would know where to click (White 2011). In order to emphasize the relation between text and image, an important feature of both the “explore” and “compare” modes, we added a simple interaction, known as “brushing,” so that hovering over a single event in either the text or the image would simultaneously highlight both elements, as well as the corresponding location on the chart’s key (Stasko 2007). For the “lesson” mode, we augmented the features developed for the other two modes with a more guided experience, akin to the lesson that Peabody described in her textbook, through proceduralized interaction (Bogost 2007). In the lesson, users must read each event, one at a time, translate it into color, and then place the colored square in the appropriate location on the grid. Through enhanced user cues, such as converting the cursor to a pointer as it hovers over the grid, and highlighting empty squares as the user hovers over them, users are guided through a digital version of the interactive lesson that Peabody envisioned in print.



Explore

Mouse over each event to see its position on the grid.

Reimagining Peabody's historical visualization scheme for the web helps to underscore how she understood interpretation as a fundamental part of the process of perceiving visualizations. Her visual design bears very little relation to the immediately intuitive images that we associate with visualization today. And yet, for Peabody, the abstraction of the chart was part of its purpose; she intended her charts to be individually interpreted by each person who encountered them. More than that, she envisioned her charts as lessons in themselves--lessons that often took time and effort in order to complete. In this way, the interactions she envisioned, while made quicker and more intuitive through their digital recreation, lose some of their original intent, in that Peabody did not identify efficiency as a feature of her designs. Instead, she viewed the interpretive process--sometimes difficult and often slow-- as the best source of historical knowledge. The "lesson" of *The Shape of History*, as distinct from Peabody's original scheme, is a reminder of how little interpretation is intended-- even if it is still required--when encountering visualizations of data today.

The Floor Chart: Reimagining Embodiment through Physical Computing

While the digital version of the project emphasizes Peabody's interest in facilitating interaction and interpretation, it does not convey the embodied aspects of the original interaction; looking at a screen is a far different experience than walking around a rug-sized chart on the floor. To reimagine this embodied mode of interaction, we designed a one-meter by one-meter floor chart, consisting of a matrix of thirty by thirty individually addressable light-emitting diodes (LEDs). Each LED corresponds to one subsection of Peabody's original chart, so that the 900 possible events can be represented. (We cannot account for multiple simultaneous events, however). The LEDs can be pre-programmed via custom software, which makes use of Adafruit's NeoPixel library. We are also in the process of developing a flexible touch interface, using conductive copper tape and neoprene, so that the LEDs can be controlled through a soft button-like interaction. Both the LEDs and the touch interface are controlled by an Arduino Mega 2560 microcontroller.

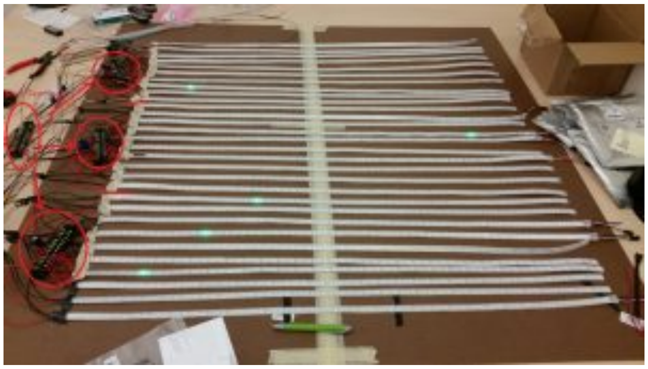

Figure 4. The LED matrix.

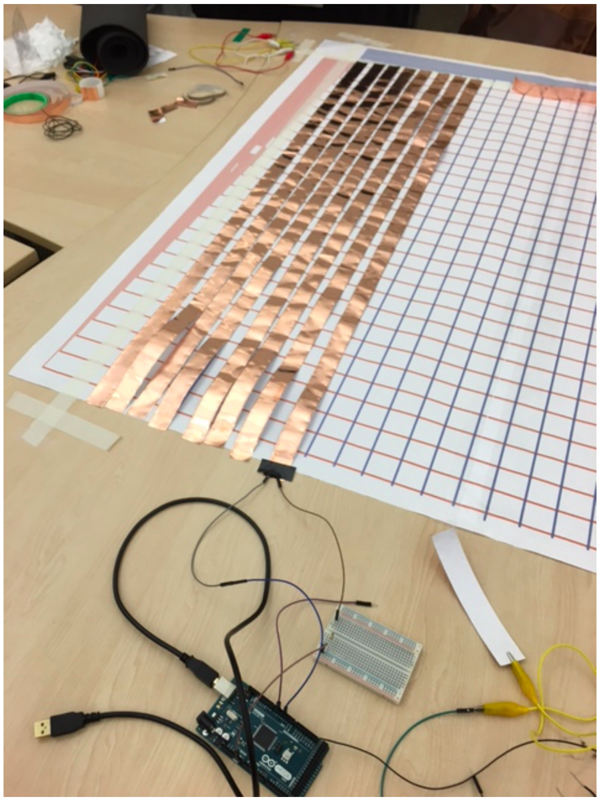

Figure 5: The touch interface in progress.

We view this project as one of speculative design (Dunne and Raby 2013). Since Peabody's original floor charts were not preserved, we must speculate about everything from the size of the chart, to the colors employed, to the events depicted. While we have textual accounts, in Peabody's correspondence, of how nineteenth-century viewers would interact with the floor charts, the original charts were obviously not programmable. What the reimagined floor chart teach us, then, is about how we might incorporate embodied elements into current visualization design practices, as much as about how viewers interacted with large-scale visualizations in the past. It also reminds us about the labor involved in fabricating the original charts. (Peabody complained about the magnitude of the task in her correspondence). The work of data visualization, while not always expressed in physical form, is always the work of many hands.

Conclusions and Next Steps

In their foundational essay on historical fabrication, Devon Elliott et al. observe that “working with actual, physical *stuff* offers the historian new opportunities to explore the interactions of people and things” (2012). In this project, we have sought to extend these opportunities for exploration to include the interactions of people with data, as well as with their visual display. Our project underscores the foundational role of interpretation in designing and perceiving visualizations; and shows how interaction is crucial to the interpretive process. It also points to future modes of visualization, not yet imagined, that might better emphasize embodied ways of knowing. In terms of next steps, for the website, we plan to think through what a more scholarly version of the site, with room for more explanatory text, might look like. For the physicalization, we are continuing to implement the touch interface. From there, we will focus on the aesthetic aspects of the rug, exploring options for light-diffusing fabrics to frame the LEDs, and light-blocking materials to create the grid-lines.

Introduction

Advances in technology and digital access have paved the way for the improved utilization and interpretation of scientific analyses of humanities materials for digital humanities studies. Integrating scientific analyses with humanities and curatorial knowledge (STEM: science, technology, engineering, and math, to STEAM: science, technology, engineering, **art**, and math) is a critical multidisciplinary approach for expanding the full potential of scientific techniques and technological advances, and realigning complementary disciplines that have been artificially segregated. Scientists and curators have exposed hidden and previously unknown contextual information within original source materials, such as changing “subjects to citizens” on the Rough Draft of the Declaration of Independence (Library of Congress, 2010). Hyperspectral imaging provides additional data layers by capturing images of documents in distinct narrow waveband regions of the visible and non-visible spectrum—from ultraviolet through visible to infrared. The cube of captured digital image files contains a wealth of information, but requires significant interpretation to process and analyze the collected data. Scientists, scholars, and students in both art and science disciplines have been collaborating to glean new information from historical manuscripts. The Library spectral imaging program includes a spectral reference database and integration of data from other non-invasive analytical techniques to create a full analytical mapping of heritage documents and objects for non-destructive analyses of collection materials (France, 2016)

Digital imaging capabilities allow researchers to characterize pigments and inks on the document, retrieve hidden and lost text, and illuminate production and creation methods. The range of data captured allows greater access to the information available from fragile historic documents, including the 1507 Waldseemüller World Map and the 1513 Ptolemy *Geographia*, where investigations revealed links to the same original printing location (France, 2016). *Scriptospatial* (a term originally coined by Toth and France to refer to the viewing of associated imaging and materiality data linked on an image of a historic document) refers to applying a spatial information system approach to documents, creating an interactive interface for scholars and scientists to interact with the object and the data. Scriptospatial representations of digital data from documents utilize an accurate coordinate system that links scientific and scholarly analyses to the creation of a new digital cultural object (DCO), allowing inferences to be drawn to generate new knowledge. This approach to viewing digital cultural materials in multiple layers applies an archaeological approach toward uncovering and interconnecting information strata of historic and modern documents. Scriptospatial mapping of documents with an accurate coordinate system allows the layering of scientific and scholarly analyses to the DCO. This allows inferences to be drawn to generate new knowledge through analysis of the data linked to spatial points (or areas). This approach to viewing the DCO applies a GIS methodology toward uncovering and interconnecting information layers of cultural heritage artefacts, just as in the case of archaeological strata. Utilizing an object-oriented approach in conjunction with the spatial data layers allows the mapping of spatial and temporal data with increasing complexity. Examining and explaining the physical, spectral and chemical properties of these historic materials permit scientists and scholars to link these scientific analyses to other data about the creation of the object.

Digital spectral imaging of cultural heritage objects at the Library of Congress has capitalized on over a decade of research and development into not only spectral imaging and processing, but also the development of standard spectral image products (France et al, 2010). Advances over the past decade by an experienced team have led to an advanced capability to study cultural heritage objects with a robust spectral imaging system that provides large-format, high quality images and standardized data output using advanced commercial off-the-shelf components (Christens-Barry et al, 2009).

Developing an object-oriented approach to data access and sharing requires integration of spectral imaging with data from other sources in a variety of formats. This requires effective spatial metadata to allow linkages to specific locations within the images. This is necessary not only to register locations on the same section of a manuscript leaf in various spectral bands, but also to link other images and transcriptions with the spectral images. Based on geospatial mapping and layering of data used to identify points on satellite images, the same technologies, work processes and skills can be applied to spectral images of manuscripts: A camera collecting images over a manuscript is similar to a satellite collecting geospatial data over the Earth. Using technologies developed for "geospatial" systems to link each point on the globe with images from earth resource satellites and data collected from other instruments, spectral imaging can link the "scriptospatial data" from each point on a manuscript with images from various imaging and scientific devices. This provides a standardized method to support links between images and data from the same object location.

With multiple data entries for samples, precisely defining the specific point where the sample or scientific data collection takes place is critical in comparing data from different research types or objects. For samples taken from a larger, non-uniform, heterogeneous object such as a manuscript, textile or painting, the spatial location of the sample point on the object must be defined to be able to integrate the data from various research tools. Spatial metadata elements will allow linkages to specific locations on an object, potentially within images of the objects. Scriptospatial data can serve as an interface for scientific dialogue in "one shared layer," linking data from various sources for in-depth studies and analyses of a specific research topic or object.

In many current research databases, the metadata elements for spatial location are not provided to capture detailed data on where an instrument collects data, or a sample is taken. This is not an issue for uniform, homogeneous samples of paints, pigments, media or other samples, but is critical for samples taken from a heterogeneous object like a painting, manuscript or textile. By defining a Cartesian coordinate system on an object or image of an object, as well as the degree of precision required, specific sample points on an object can be defined. This allows integration with other images of the same object and scientific samples from the same point.

In its Scriptospatial Visualization Initiative, the Library of Congress PRTD has capitalized on developments with geospatial systems to apply Thermopylae "i-spatial" support and Google Map tiling and data formatting to the integration of large and complex visual scriptospatial datasets populated with scientific data from various instruments, research topics or objects. This provides data access in "one shared layer" of scientific data. This is an important first step in capitalizing on the three decades of technology development by the GIS community to advance preservation science and cultural heritage data sharing and research. The additional unique component will be the layering of scholarly research interpretations and publications, enabling ease of access to a rich resource of data directly linked to the original object. This will reduce the challenges faced with searching through data that is not well catalogued, or yet searchable without this expanded document interpretation and linking of scholarly knowledge.

Integrated access to associated source material scientific data adds contextual value, provenance information, and can reveal non-visible information hidden within the original document. The Scriptospatial approach allows layering of scientific and scholarly or curatorial research data within one location, enhancing the analysis and depth of knowledge off the original document, and creating a more effective interface for interaction with historic materials (France et al, 2010). The innate layering of multiple sources of information of the Shared Canvas Model (Sanderson and Albritton, eds, 2013) onto one view of an object, coupled with the strong annotation capabilities of the Web Annotation Data Model (Sanderson et al, eds, 2016) raises interest in the possible integration of the Scriptospatial model with IIIF efforts (International Image Operability Framework). One of the challenges we face with the current data deluge, is how to effectively access, select and link appropriate data and information. Scriptospatial is a value-added data approach, creating cohesive structured management of multidisciplinary data. The authors have been engaging with other US, European and United Kingdom colleagues to create a cohesive integrated and collaborative approach to this visualization.

Reading the Norton Anthologies: Databases, Canons, and "Careers"

What type of canon do the Norton anthologies of literature construct? And how has that canon changed over time? These questions are somewhat unusual for humanists in that their answers could be framed not in a syllogism or thesis, but rather in the forms of the list and the table—and extensive ones at that.

We wanted, first, a way to see who goes in and who goes out of this canon that we so often teach from. In a sense, this project is as much about pedagogy as it is about literary criticism: We have no investment in the Nortons as being representative of "The Canon," but rather see them as a medium through which undergraduate and graduate students of literature encounter major works and begin to formulate their ideas about the literary field. Following John Guillory, the Nortons seem to be one of the primary means by which the cultural capital of literature gets distributed and reinscribed within the university. How, then, has this medium—of texts and canons that inform courses, students, and scholars—changed along with literary criticism over the past half-century?

Our team built a database containing every work and excerpt featured in the Norton Anthologies that we have studied so far, with room to grow for those that remain. This allows us to easily see what we have been thinking of as the "careers" of both authors and individual works over time. How, for instance, have the works selected to represent Milton changed over time? When was Margaret Atwood first added to any Norton Anthology? Which poems represent Langston Hughes in the *Anthology of Poetry*? Are they different from those that represent him in the anthologies of *World*, *American*, or *African-American* literature? What proportion of authors in the anthologies are women, and how has that changed over the last fifty years? Which authors have been cut from the anthologies? And which authors or works replaced them?

In order to answer these questions about the people and ideas admitted to these canons, we needed to restructure the data from the Nortons' tables of contents into a format that could be queried and would reveal the relationships among many different works and selections from works across a variety of different manifestations. The problems this poses from the perspective of data structure are easiest to think through with a major author like Shakespeare, who appears in every anthology relevant to his work. We need to know which works were selected to represent Shakespeare in each edition of every anthology in which his works appear. For example, which Shakespeare plays appeared in the first edition of the *Norton Anthology of English Literature*, and which in next eight? How do those selections compare to the ways in which Shakespeare is represented in the anthologies of *Drama*, *Poetry*, *Western*, and *World* literature, across each of their individual editions?

We achieved this by creating a structure based on a set of *n*-deep parent-child relationships and a number of many-to-many connections, using a web interface for parallel data entry and validation between several collaborators simultaneously. Using this structure and the Shakespeare example above, *King Lear* becomes a "child" of Shakespeare, and Lear's "Blow, winds … !" speech from Act III a child of *King Lear*. Because of this nesting, we can then measure not only which anthologies *any* work of Shakespeare's appears in, but, of those, which contain *King Lear* in full, which only have the excerpt of Lear's speech, and which contain other parts of *Lear*. This allows us to be more precise about the ways in which we count authors' presence and absence across all of the anthologies that this project will eventually consider. This data entry interface was built with the Django, an open-source web application framework, and the code is publicly accessible on GitHub. The database will be demonstrated and described in more detail during the presentation.

Having produced new editions and types of anthologies semi-regularly for more than fifty years, W.W. Norton & Company has been in the business of binding literary canons longer than anyone else still publishing. Since M.H. Abrams edited the first *Norton Anthology of English Literature* in 1964, numerous editions and kinds of anthologies have followed: *The Norton Anthology of American Literature*, *World Literature*, *Western Literature*, *Poetry*, *Drama*, *Theory and Criticism*, *Short Fiction*, *Literature by Women*, *African American Literature*, *Latino Literature*, *Jewish American Literature*, etc.

Much can be learned about the ways in which the Nortons were designed from these titles alone. First, the largest anthologies are defined by both geography and a linear temporality influenced by conventions of periodization. *The Norton Anthology of World Literature* lays claim to it all, from Afghanistan to Zimbabwe, and from *Gilgamesh* to Orhan Pamuk. *Western Literature* claims a smaller (if vaguer) part of the world, and *English* and *American* literature focus on national literatures, including postcolonial and expatriate writers within the bounds of the nation-concept. While these geographic anthologies are ostensibly genre-agnostic, others are genre-specific (*Poetry*, *Drama*, *Short Fiction*). And the last type focuses on writing by and about writers of a specific gender (*By Women*), ethnicity (*Latino*), or religion (*Jewish*).

One of the premises we read as implicit in the Norton's design, then, is that some authors and works become significant enough to include only in specific contexts. Making it into the *World Literature* anthology seems to denote significance at a greater level than inclusion in the *Western Literature* anthology alone would. Likewise, seeing a writer anthologized in *Short Fiction* but not *World Literature* seems to imply a significance limited to that literary form. Canon formation has always relied on a logic of a ranking or tiering, and the pool of authors and texts against which a given work "competes" is greatest at the largest scale of population. We argue that the geographically bound Nortons can be read in such a way that they imply a hierarchy even among the canons the anthologies already connote.

Of course, all of the decisions we measure across these many tables of contents are underwritten by a human element. Many practical and historical factors that exist at a slant to the question of a work's "canonicity" attend the production of an anthology that stretches to more than 6,000 pages, serves tens of thousands of instructors and students, and our analysis attempts to account for these factors. A quantitative approach is necessary but not sufficient to read the ways in which the Nortons have represented and continue to represent works that, taken together, lay claim to the status of a national, generic, or global literature. Two key examples of the incommensurability of the form to its implicit claims: Because of its length, the novel is poorly served by the anthology form. Some shorter novels and novellas do get anthologized. But, more often than not, writers who are primarily known as novelists are represented by a single short story, or an excerpt from a novel. The second overarching practicality is the influence of authorial estates and the cost of printing rights, especially for 20th and 21st century authors.

As a way of approaching these institutional and qualitative questions, we have begun a set of interviews with Martin Puchner, the current general editor of the *World* and *Western* anthologies, and will discuss some of his insights into the decision-making process in the presentation. Among these include the influence of instructor and student surveys on texts that get selected, the impact of rights costs on the texts that get chosen for a given author, and the place of editorial intervention in relation to these powerful practicalities.

Our database and the attendant institutional research on the Nortons as the product of both scholarly editing and the demands of the market allow us to see the trajectories not only of individual authors and works, but broader trends of inclusion and exclusion in the Norton's canon. By gathering data about both the works and the authors who wrote them, we reveal the ways in which the Norton has responded to the expansion of the literary canon, growing in size while simultaneously giving a greater share of its pages to authors and ideas that would not have been considered canonical 1962. In the process, we find authors whose literary reputation has waxed or waned (or both); those whose names have been a constant presence, but whose representative works have dramatically changed; those who were slated for canonization but never "made it;" and those who have arrived late but seem to be here to stay.

Like many of the Stanford Literary Lab's projects, "Reading Norton Anthologies" operates at several scales at once. We are interested both in individual texts and authors, as well as broader patterns of representation and contextualization within the confines of this object that occupies liminal spaces between statement and syllabus, and between the market and the canon.

Introduction

With many ongoing debates (Gold, 2012) and "unwritten" histories (Nyhan and Flinn, 2016), the research practice of the Digital Humanities (DH) has been around for 70 years. Many works have been trying to draw general conclusions of the disciplinary structure (McCarty, 2003; Gold, 2012; Terras et al., 2013; Schreibman et al., 2016; Nyhan and Flinn, 2016), and have pointed to the potential usefulness to analyse the discipline from statistical aspects. The usefulness focuses on describing the intellectual structure, scholarly interactions and disciplinary development of DH. Some studies have dedicated their attention to these matters (Grandjean, 2016; Nyhan and Duke-Williams, 2014; Quan-Haase et al., 2015; Wang and Inaba, 2009), or have focussed on one of these topics (Sugimoto et al., 2013), but few of them have engaged either with the bibliometric network method, or with the latest large-scale scholarly datasets to study the DH community as a whole.

Therefore, to fill this gap, based on a provisional dataset that has been compiled from core DH journals, this study performs an exclusive all-author co-citation analysis (ACA) with the 200 most cited scholars by fractional citation count to map and demonstrate the intellectual structure and to identify the most influential scholar groups and topics within DH.

To the best of our knowledge, this study is the first to apply bibliometric methods to visualise DH knowledge structure and the scholar clusters. This research output will make a valuable contribution to the current discussions and debates about DH knowledge structure and wider scholarly networks.

Methodology

With ACA as the main methodology, the research contains four steps, and each with a different methodology: building a DH citation index according to the publications of these journals; selecting authors as the core objects for citation analysis; assigning scholars to different distance-based clusters by calculating the author co-citation matrix to similarity matrix (Waltman and van Eck, 2013); finally, visualising the DH citation network which aims to show the scholar clusters, and the knowledge structure and diffusion of DH.

The three DH core journals that our dataset has been constructed from are: "*Computers and the Humanities*" (*CHum*), "*Digital Humanities Quarterly*" (*DHQ*), "*Literary and Linguistic Computing*" (*LLC*) (now "*Digital Scholarship in the Humanities*") (*DSH*). The bibliographies as well as the metadata of all their publications (including the reviews and editorials etc.) published until June 2016 have been collected. It should be noted that none of these journals spanned the whole period selected (1966-2016): *CHum*, the first DH journal started in 1996, and ceased publication in 2004; *LLC/DSH* began in 1986; *DHQ* began in 2007. Figure 1 shows the total publications each year from 1966 until June 2016 for these journals.

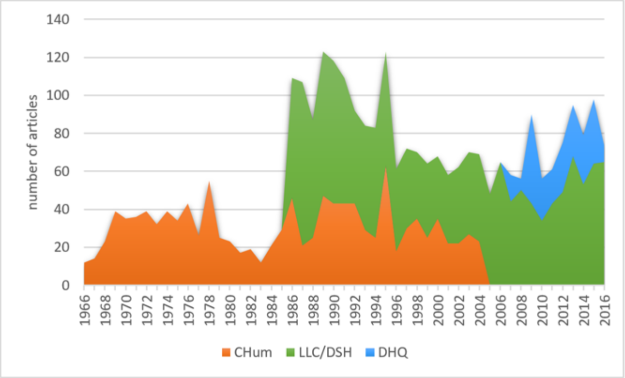

Figure 1. In total, 3,068 journal articles: *CHum* (1,195 articles with 26,033 citations), *LLC/DSH* (1,633 articles with 28,501 citations), and *DHQ* (240 articles with 4,289 citations)

Author co-citation analysis (ACA) can reveal the intellectual structure of a field from its academic publications by calculating the frequencies with which two authors are cited together. That is to say, if an article cites at least one article of author A, and at least one of author B that is different from the one of A, the co-citation count increases by 1. The more co-citations two authors receive, the more likely their publications and researches are related (Bellardo, 1980). Therefore, the clusters of related authors indicate the networks of research topics, or influential focuses within a discipline.

The initial findings with the top cited 200 authors displayed on the maps (see the provisional maps in Figure 2 and Figure 3) have provisionally revealed five sub-fields within DH.

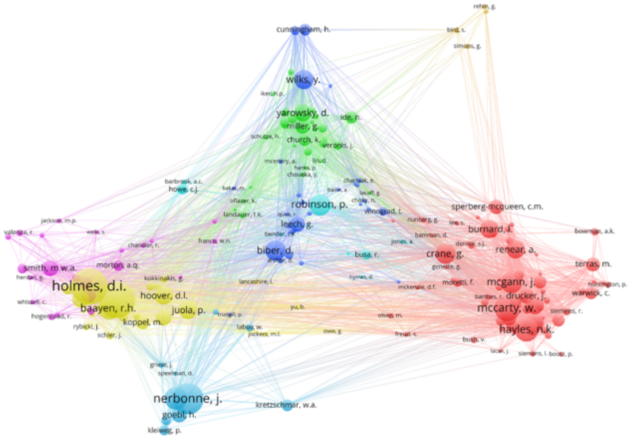

Figure 2. The provisional ACA network map in DH, data from journals *CHum*, *LLC/DSH*, and *DHQ*, 1966-2016, created using VOSviewer

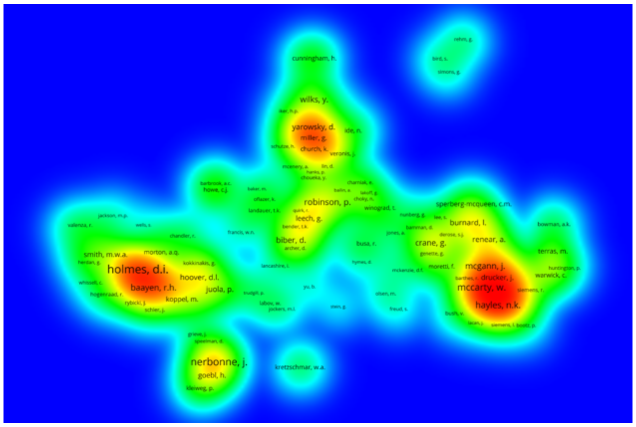

Figure 3. The provisional ACA density map in DH, data from journals *CHum*, *LLC/DSH*, and *DHQ*, 1966-2016, created using VOSviewer

Both of the maps (Figure 2 and Figure 3) are distance-based. Each node on the map represents an author, and the distance between two authors is their relations (the closer the distance, the stronger the connection). Authors are distributed quite unevenly, and this makes it easy to identify clusters of related nodes. The size of the node represents the citation count this author received, and the higher the citation count is, the bigger the node. On the density map, the density value depends on the size, number and distance of the nodes around it, so the higher the density value, the colour is more red than blue.

Both maps have revealed the general structure of the scholarly communication between DH scholars via publications. Horizontally across the centre of the map, there is a loosely connected circle of five DH scholar clusters: centre (focused on "Leech, G"), top (focused on "Miller, G"), bottom (focused on "Nerbonne, J"), left (focused on "Holmes, D.I"), and right (focused on "McCarty, W"). The clusters distribution on the density map reveals that there is a clear separation between top, centre, right clusters to left and bottom clusters. Especially the right cluster (focused on "McCarty, W") and the left cluster (focused on "Holmes, D.I") turn out to be denser than other clusters. This shows that these two clusters are more significant and have more citation influence. According to the provisional analysis, these five clusters appear to be associated with five different DH research topics: English study at the centre; general historical literacy and information science on the right; language modelling and natural language processing at the top; statistics and text analysis on the left; computational linguistics particularly on Dutch and German speaking at the bottom. These five clusters, however, are also grouped into two different bigger groups. The English study, language modelling, and general historical literacy seem to be in one group which is more related, while the statistics and Dutch-German linguistics are also very closely related to each other.

Limitations and Future study

This research is part of the first author's ongoing PhD study, funded by UCL ORS scholarship and based at the UCL Centre for Digital Humanities. The doctoral reseach maps DH intellectual, social and environmental structures using the Invisible College model (Zuccala, 2006).

There are some limitations that need to be noted, such as the citation lag time. In order to build up a citation record for co-citation, it takes around five to eight years (Hopcroft et al., 2004). This could explain that certain recognisable authors might not appear on the maps yet. Also, because the co-citation method studies the knowledge base as its subject, the map emphases more on authors published some time ago, which might not include the "new comers".

In the future work, the ACA study will be extended to include more citation data. The ACA study will be divided into discreet periods to construct maps of different DH development stages. Given that different journals have different topical foci, the research will also analyse individual journal to discover its attribute.

Negotiating Sustainability: The Grant Services "Menu" at UVic Libraries

Lisa Goddard
lgoddard@uvic.ca
University of Victoria, Canada

Christine Walde
cwalde@uvic.ca
University of Victoria, Canada

Brief summary

This paper provides a brief overview of library best practices for digital curation, with particular attention to the areas that highlight disciplinary tensions between library science and the humanities. The authors introduce the University of Victoria's grant service "menu" for digital preservation and hosting services, and outline some of the most promising models for balancing creativity with sustainability in DH project design. We will suggest roles for libraries, researchers, administrators, and funders in helping to create technical and social conditions that nurture sustainable research projects in the digital humanities and beyond.

Abstract

Knowledge building is an iterative process that refines and extends previous research. Through citation, we acknowledge our debt to scholars and theorists whose work enables our own. The ephemeral nature of the digital world threatens to destabilize a centuries long system of scholarly communication and knowledge sharing. In a print ecosystem many immutable copies of an object are distributed globally and are curated by network of organizations. In the digital world a single copy of an object is served from a central location. Digital content is thus susceptible to manipulation, corruption, and erasure. The key to analog preservation is to ensure that artefacts remain the same. Digital preservation, in contrast, requires "active management" comprising constant changes, patches, and updates. Objects become quickly obsolete as the environments around them change.

Funding agencies are putting increased pressure on researchers to include sustainability plans in funding applications (NEH 2016, SSHRC 2016). Researchers often turn to the University Library to provide preservation solutions for digital projects without fully understanding the technical, policy, and funding implications of these requests. Libraries have made significant strides in planning for the long-term preservation of the many thousands of digital objects in our collections. Digitization projects adhere to strict standards for resolution, colour management, and file formats (FADGI 2016). Digital asset management systems like Hydra/Fedora provide a single place to store objects along with descriptive and administrative metadata that helps to determine the preservation actions that should be taken against each object (Goddard, 2016). Those actions include auditing and bit-checking of file systems to ensure against data loss, format migrations as media and file types become obsolete, replication of objects across different technology stacks and jurisdictions, and discovery interfaces that ensure continued discoverability and access. Libraries are building national networks that will allow us to replicate data across multiple jurisdictions to mitigate against disasters both natural and human (DPN 2016, Canadiana 2016, CARL 2016). Despite concerted efforts, only a handful of library repositories have so far met the stringent conditions that are necessary for certification as a Trusted Digital Repository, which requires technical and policy elements including plans for long term staffing and funding, and contingency plans in the event of organizational failure (CRL, 2015). Ultimately, libraries still can't make guarantees about preservation for digital objects in our own collections, even those that are subject to internationally recognized best practices. This problem is compounded when DH research projects fail to adhere to adequate quality standards for objects (e.g. images, texts, video, maps, mark-up) and overlook established metadata models and vocabularies.

To this point we have outlined the challenges of curating fairly static digital files, but most DH projects are far more than the sum of their digital objects. Many DH research projects are complex software stacks with many layers of tools, objects, code and dependencies. If a project is built on Drupal, for example, librarians will have to not only maintain all of the unique objects and code produced by the project, but they are also committed to maintaining a specific version of a rapidly evolving software platform -- a version that will likely be obsolete before the project concludes. Drupal is, at the very least, well documented and widely deployed. Many DH projects also include custom-built tools, the inner workings of which are known only to a handful of people on the research team. The complex technology profiles of contemporary DH projects require ongoing active management including patching, tending, and rebuilding over time (Burpee, 2015). While the library may have sufficient resources to steward one or two unique project environments, this approach cannot scale to hundreds or even thousands of projects over time. In the current technical and funding environment is simply not possible for libraries to provide high-level curation for the enormous variety of funded digital projects that are produced by researchers within their organizations.

Libraries alone will not solve the problem of sustainability in DH projects. A fundamental characteristic of sustainability is that it must be established as a key design principle from the outset. It is almost impossible to retroactively render a project sustainable without rebuilding from the ground up. Initial choices about technologies, data models, formats, and documentation will influence the likelihood that a project will still be accessible in a decade. One complicating factor is that sustainability is largely at odds with a researcher's freedom of choice when it comes to decisions about platforms, tools, and data models. Truly sustainable DH projects will require a level of standardization that is far from the current norm in DH project development, and which is unlikely to be unequivocally embraced by humanists. Research is an experimental process, and technological constraints can stifle creativity and independence of action. Models, by their very nature, seek to simplify, while the humanist tradition revels in nuance and complexity (McCarty, 2005; Quamen, 2013).

Leslie Johnston from the Library of Congress suggests that libraries can pursue two models for preserving complex DH projects. The first approach is to "preserve the content but forgo the look and feel. This is often extremely unpopular." The second is to "preserve the content and the look and feel exactly as they were implemented. This is often close to impossible." (Johnson, 2013) The tension between these two models is where libraries, researchers, and funders need to more clearly outline our assumptions and expectations.

The University of Victoria Libraries have developed a suite of preservation services for grant funded projects in order to plainly articulate our competencies, assets, and constraints (Goddard and Walde, 2017). This document acts as kind of a "menu" of services from which researchers can select as they develop their grant applications. These include the use of our Hydra/Fedora4 digital asset management system, metadata expertise that extends to consultations around interoperability and linked data, web hosting and discovery, exhibit building software, copyright consultation, open access publishing, research data management, and digitization services. We provide template paragraphs related to sustainability, preservation, open access, and knowledge mobilization that researchers can easily repurpose for any given funding proposal. We include a break down of the in-kind value of each of these services, along with any costs that will be charged back, so that researchers can easily estimate the value of the institutional commitment. We hope that this approach will enable critical conversations about sustainability to happen during the grant writing process, rather than towards the end of funding cycles as has been too often the case in the past. In order to offer our "gold standard" preservation services libraries will have to be involved in early conversations about technology preferences and data models. We certainly don't assume that all decisions will be dictated by curation needs, but rather that our consultation will enable researchers to make clear-eyed decisions about the impact of their choices on sustainability.

The preservation "menu" is an appealing model for researchers, as it enables them to quickly understand the variety of services and in-kind contributions that the library can offer in order to strengthen a funding application. There are also advantages to the library. By tying preservation services to grant funded projects we can avail of a rigorous review process that helps us to direct library resources towards research that has been deemed valuable by a network of disciplinary experts. It provides an easy formula for calculating in-kind contributions for letters of support, and to some extent standardizes the process of writing those letters. It helps to promote librarians as desirable co-applicants and collaborators on funding applications. It underscores to administrators the library's value as a university research support. This model also provides mechanisms whereby grant funds can flow back into the development of new features for the library's digital asset management and publishing platforms.

Susan Brown notes that "successful technologies rely on social resources." (Brown, 2016) Part of our challenge is to muster support from researchers, librarians, administrators, and funders to create optimal conditions for long-term digital curation. The conversation about long-term preservation will be an ongoing negotiation that bridges different disciplinary perspectives, and balances ideals with resource constraints. Just as the traditional model of scholarly print publishing has shaped the means of scholarly production through the last two centuries, these conversations will ultimately will help to shape the future of humanities research platforms, resources, and methodologies.

"A Trace of this Journey": Citations of Digitised Newspapers in UK History PhD Theses

Paul Matthew Gooding
p.gooding@uea.ac.uk
University of East Anglia, United Kingdom

> "In two weeks, despite these notes, I shall no longer believe in what I am experiencing now. One must leave behind a trace of this journey which memory forgets" (Cocteau, 2013).

Academic citations are prostheses for the scholarly memory, providing traces of a text's origins. They are also, taken collectively, a powerful source of information on scholarly influence, links between authors, and academic publishing trends. This paper will present work in progress to discover the extent to which citation patterns by UK historians have been affected by digitisation of historical newspapers. Previous studies into digital resources have used citation analysis for impact analysis (Meyer *et al.*, 2009), but faced problems gathering accurate data due to researchers' unwillingness to cite digital resources. Text mining mentions of titles within a digital resource offers a solution to this problem; indeed, Milligan (2013) has successfully used techniques from Natural Language Processing to track citations of major Canadian newspapers in Canadian PhD theses. However, there are local variations around academic practice, and cultural heritage digitisation, and to date there has been no large-scale study of digital resource citations in the United Kingdom.

This paper will present my efforts to mine newspaper citation trends using over 6,000 history theses submitted at UK Higher Education institutions, from 1999 to 2015. It will also consider the implications of text mining using legal deposit library collections. Its significance is therefore twofold. It is the first study to use text mining to track citations in UK history theses, thereby providing insights into the effect of local digitised primary sources. Second, by collaborating with British Library Labs, it provides an important test case of the possibility of exploring the text mining exception in UK copyright law. This study therefore focuses on two key research questions:

- What does citation analysis of UK history theses tell us about the impact of historic newspaper digitisation on early career historians in the United Kingdom?
- How far does the ability to text and data mine copyrighted materials provide for data driven approaches when applied to legal deposit library collections?

Research context

In the last fifteen years several studies have proposed models for evaluating the impact of digital resources (Warwick *et al.*, 2006; Meyer *et al.*, 2009; Tanner, 2012). Citation analysis is commonly used in impact evaluation, and is a well-established bibliometric technique for impact analysis (MacRoberts and MacRoberts, 1989). As part of the wider field of bibliometrics, citation analysis has been used to judge the impact of academic publications and digital resources (Meyer *et al.*, 2009). Citations are proxy measures of how frequently a document or resource is used, founded on the assumption that there is a strong positive correlation between the number of citations that a resource or article attracts, and the quality of that resource (Smith, 1980). The reality, though, is that citation practices are not always followed or understood by academics. Smith (1980) noted several reasons a scholar may choose not to cite a document: inability to obtain the document; inability to read a foreign language; lack of relevance to their work; or lack of awareness of existing work. There are further reasons for digital resources; not least a lack of awareness of how to cite them (Sukovic, 2009), and disciplinary unwillingness to acknowledge their usage (Meyer, 2009). As a result, the traditional method of mining only citations provide an unreliable picture of citation levels of digital resources.

Furthermore, there is a need to account for the varied local and national context within which researchers operate. In Canada, for instance, there is a feeling among scholars that the "limited and fragmented" (Kheraj, 2014) newspaper digitisation programme lags behind nations such as the USA, Australia and United Kingdom. The prominence of *The Toronto Star* and *The Globe and Mail* mirrors the early years of newspaper digitisation in the United Kingdom, where the ubiquity of the *Times Digital Archive* encouraged some to overstate its representativeness (Bingham, 2010). Contemporary digitised newspaper resources in the UK by contrast, tend to aggregate dozens of newspaper titles into a single resource. This paper therefore explores the likelihood that this aggregation process may have caused different citation patterns among UK researchers, who are the largest group to access these resources (Gooding, 2014), providing a comparison with the differing Canadian context presented by Milligan.

Methodology

To achieve this, I will focus on newspaper titles from two British Library resources: *British Library Nineteenth Century Newspapers (BNCN)* and *The British Newspaper Archive (BNA).* I intend to identify mentions of newspapers by title within the full text of UK history theses. The dataset comes from EThOS, a national service which makes UK doctoral theses available online for searching and reading. EThOS contains approximately 440,000 records relating to theses awarded by over 120 institutions. It provides a comprehensive, systematically collected dataset for comparison of citation trends over time. Around 160,000 records provide access to searchable full text, and I have worked with British Library Labs to identify a subset of history theses published from 1999 to 2015; in total, over 6,000 theses were identified using Dewey Decimal Classifiers, covering eight years before and after the launch of BNCN in 2007. These theses will be searched using Natural Language Processing techniques to identify the incidence of specific newspaper titles that are included in BNCN and BNA, allowing me to identify how many theses use a given source, and how frequently each source was used.

This project also acts as a test case for text mining of British Library collections. In 2014, the UK government introduced an exception to copyright law to ensure that researchers undertaking text and data-mining for non-commercial purposes would no longer infringe copyright (Intellectual Property Office, 2014), without requiring that publishers took steps to guarantee the availability of suitable datasets for text mining. In reality, this means that there are many potentially valuable data sources that could be legally studied, but no infrastructure to do so. Starting with the British Library's PhD thesis holdings, I intend to work with British Library Labs to explore the possibility of opening up further datasets for text mining.

Conclusion

This paper will explore the ways in which historical newspaper digitisation have impacted upon historiography among early career researchers in the United Kingdom, by tracking citations of digitised newspaper titles over time in the full text of over 6,000 PhD theses. This is the first study to apply text mining of digital resource citations to the UK context. It also provides an important case study of text and data mining in legal deposit library collections, in the light of current limitations to the UK copyright exception. In doing so, this project will not only illuminate the ways in which digital resources can affect local research practices, but will demonstrate the utility of text mining in addressing the methodological limitations of citation analysis for digital resources. We must adopt new computational methods to ensure that the traces of this use are not wiped away by citation practices which continue to de-emphasise the role of digital resources in contemporary research.

Site-specific Cultural Infrastructure: Promoting Access and Conquering the Digital Divide

Andre Goodrich

North-West University, South Africa

Juan Steyn
juan.steyn@nwu.ac.za
North-West University, South Africa

The ability to create and deploy networking technologies able to deliver relevant content over multiple platforms has until very recently depended on access to costly technology, infrastructure and expertise. The result has been a digital divide that is particularly acute in highly unequal economic contexts like South Africa. The potential of ICT to democratize the public realm, currently dominated by large media houses catering to individuals with the economic means to access costly data services, has not been realized.

The increased availability of cheap, open-source technologies, along with the growth of communities of users around these technologies, has made possible new kinds of digital publics beyond the abovementioned constraints.

Drawing on these technologies we have developed a freestanding platform capable of empowering users to create, publish and access their own network-dependent projects. We have done this using a solar-powered single-board computer (Raspberry Pi) and have tested its application in two projects: a site-specific digital literature project; and a virtual site-specific museum of apartheid-era forced removals. Both are based in the city of Potchefstroom in South Africa's North West Province.

Site–specific digital literature project

Site-specific digital literature, by allowing users to access place-bound, multimodal digital literature via mobile devices, opens doors for creative expression, place making as well as experiencing traditional texts in a new way. It can also contribute to a better understanding of the relationship between digital interfaces, spatiality and people and empower people in terms of what is called place-making practices (Kaye, 2000:203; Turner & Davenport, 217-220).

Byderhand (Byderhand.net, 2016), is a site-specific digital literature project launched during the 2015 Aardklop National Arts Festival in Potchefstroom, South Africa. Users accessed multimodal texts on their mobile devices through QR-codes deployed around various sites at the North-West University. *Byderhand* was awarded the Aartvark prize for a ground breaking production, and the team was approached to host similar productions elsewhere. In 2016 the *Byderhand*-project and platform were used in various educational contexts. Most recently, the *Byderhand*-team, assisted 1st additional language (Afrikaans) learners at a Potchefstroom secondary school to publish their own site-specific digital literature on the school grounds.

Although there is a demand for expansion of the *Byderhand*-project, cost and scalability are limiting factors. First, in its current form, implementing the project requires a team of dedicated members. is Second, functionality depends on the provision, maintenance and upgrading of infrastructure such as servers and physical QR-codes. On the user end, mobile data cost is a constraining factor.

Therefore, we explored the design of the infrastructure for an automated platform that could empower a low-skilled user, to create, publish and access their own projects. This was important as usability of a platform can ether promote access or restrict it through the way the interface is developed (Shneiderman, B. 2003).

The infrastructure chosen was a single-board computer (Raspberry Pi) and a platform was developed based on open standards.

Virtual museum project

South Africa's heritage landscape remains largely skewed in ways that exclude intangible heritage such as stories and memories of such events as apartheid-era forced removals. A virtual museum of forced removals aids in remedying this by offering an in situ space where people can give voice to their experience and preserve it for future generations.

The city of Potchefstroom was one of the first places where forced removals took place during the apartheid regime but little historical records exist outside oral accounts and some pictures of what took place. The platform we developed provides access for a community to tell their own story without the need for expensive infrastructure. It can provide a place for reconciliation, healing and understanding the intricacies of racial tensions within the context of a specific community.

In summary our paper reports on prototyping a cheap, scalable system, independent of electricity and data costs that can allow users to add and access content for both these projects. In particular, the paper considers the following:

1. How the prototype platform enables users to publish multimodal texts and multimedia (e.g. audio, images and video) on their own.
2. How the prototype platform provides an easy way to consume published work using entry-level smartphones.
3. The scalability of this cultural infrastructure, with regard to expanding multimodal site-specific literature and museums along with the creation of site-specific corpora.
4. Educational applications:
    a. How the platform could be ported into other applications such as freestanding, free-access libraries for schools and community centers.
    b. Educational possibilities created that can introduce students to the world of digital literature.
    c. A lesson in the value of interdisciplinary collaborations.
5. Building collaborative communities and empowering them to tell their own stories.
6. Mini-showcase of the project

Designing Tools for Macro-Scale Data Analysis in the History of Science

Elyse Graham
jean.graham@stonybrook.edu
SUNY Stony Brook, United States of America

Robert Crease
robert.crease@stonybrook.edu
SUNY Stony Brook, United States of America

Our project involves developing a new kind of digital resource to capture the history of research at scientific facilities in the era of the "New Big Science." The extent, scope, and diversity of research at such facilities makes keeping track of it difficult to compile using traditional historical methods and linear narratives; there are too many overlapping and bifurcating threads. In this talk, we will discuss existing methods of data collection and curation for a specific case project, the National Synchrotron Light Source Digital Archive. We are especially interested in the functional potential, in the context of this kind of tool development, of the humanistic concepts of narrative, metaphor, and performance.

Médias sociaux et mise en scène de l'histoire

Martin Grandjean
martin.grandjean@unil.ch
Université de Lausanne, Switzerland

Introduction

La rigueur de la critique des sources historiques est-elle soluble dans l'immédiateté et la course à l'audience des médias sociaux ? Depuis plusieurs années, les projets de médiation culturelle se multiplient, en particulier sur Twitter où la brièveté des messages se prête bien à une nouvelle forme de *storytelling* historique et dont le public est particulièrement curieux et avide de *retweeter* l'une ou l'autre photographie d'archive documentant la grande (et plus rarement la petite) histoire de l'humanité ou de participer à la commémoration d'un événement (Clavert *et al.* 2015). Mais les institutions patrimoniales et les universités ne sont pas les seules à mettre ainsi en valeur leurs collections et leurs compétences, elles sont aujourd'hui largement dépassées par des comptes créés de toutes pièces pour partager automatiquement des images célèbres ou des citations flatteuses à des millions d'abonnés, sans contextualisation ni précautions de véracité, de licence ou de liens vers la source originale. Alors que certaines de ces initiatives sont le fait de passionnés, qui s'attachent à un événement qui les touchent personnellement et ont à coeur de le faire vivre à leurs abonnés, nombre de pages Facebooks/Twitter sont en fait produites en série par des individus qui, conjointement à des comptes partageant les plus belles photos de paysages du monde, d'animaux ou de personnalités célèbres, construisent des audiences de dizaines de millions d'internautes à des fins publicitaires.

Nous proposons une analyse d'un certain nombre de comptes Twitter présentant des caractéristiques très différentes. On verra que la montée en puissance des comptes commerciaux est basée sur des stratégies relativement simples, de l'achat de *followers* à l'auto-référencement. Dans un second temps, nous établirons une typologie des usages des documents historiques à des fins de communication sur les médias sociaux. Ce classement, qui se veut également un outil pour les institutions qui seraient tentées de mettre au point leur propre projet de médiation culturelle sur ces plateformes, montrera en particulier que la palette des usages ne se restreint pas forcément au partage de ressources mais tient parfois beaucoup plus du récit et de la mise en scène.

Figure 1. Exemples de comptes Twitter à caractère historique.

Prendre la mesure d'un phénomène

Un compte Twitter comme @HistoryInPics génère quotidiennement plus de 10,000 retweets, alors que les *social media editors* de la Bibliothèque nationale de France (@GallicaBnF) dépassent occasionnellement la centaine d'interactions, malgré leurs contenus originaux et souvent présentés avec humour. Mais plus d'abonnés ne veut pas toujours dire plus d'engagement de ceux-ci, surtout quand une majorité d'entre eux sont inactifs : c'est pourquoi nous analyserons en détail les publications d'une dizaine de comptes pendant un mois. La quantification de ces audiences (fig. 2) est un passage obligé pour comprendre l'ampleur du phénomène et tenter de comprendre la nature de ces publics. Fondamentalement, si ces démarches – même commerciales – ont un tel succès, c'est qu'il est temps que les historiens se saisissent de la question.

On verra en particulier que les audiences des grands comptes peu scrupuleux se recoupent largement, un phénomène qu'on expliquera en détail par l'analyse d'un échantillon de plusieurs dizaines de milliers d'abonnés. On s'attachera également à dresser, pour les comptes d'institutions patrimoniales, une statistique des contenus les plus susceptibles de créer un fort engagement. Encore une fois, il s'agit d'adopter une posture d'observation, de décoder des pratiques numériques souvent en décalage avec les idées reçues qui circulent dans les milieux académiques et de questionner la relation ambigüe entre recherche historique et valorisation de celle-ci.

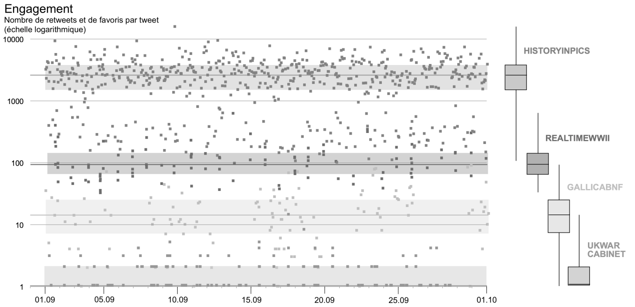

Figure 2 : Analyse d'un mois de tweets de quatre comptes Twitter partageant des contenus historiques de manière très différente (Grandjean 2014). Chaque point est un tweet dont le succès est représenté sur une échelle logarithmique de retweets+favoris. Les boîtes de droite résument la dispersion du résultat (50% des tweets de chaque compte obtient un "engagement" qui tient dans la zone définie par la boîte correspondante).

Décrire les usages

Certains mettent valeur leurs collections, d'autres en font des exercices (Steffen et Nunes Coelho 2014), cherchent le *buzz* pour lancer une start-up en communication numérique, luttent pour qu'une cause historique soit reconnue ou mettent en scène leur grand-père au travers de son journal de guerre, mais tous ont en commun l'utilisation de documents d'archives – souvent photographiques – dans leurs micro-messages.

Dans cette recherche, nous ferons la différence entre les communications basées sur la disponibilité d'archives et celles qui, pour illustrer un récit, font usage de documents d'archive (fig. 3). Paradoxalement, c'est dans la première catégorie que l'on trouve les usages les plus « purs » comme les usages les plus critiquables : d'une part des institutions d'archive qui partagent des pièces de leurs collections ou des chercheurs qui consultent des documents et tweetent les « perles » qu'ils rencontrent et d'autre part des comptes semi-automatisés qui partagent des photographies issues de grandes banques d'images, du portrait de président américain à la couverture d'album des Beatles. Il s'agit toujours ici d'un processus archive→communication. À l'inverse, la démarche communication→archive est mise en pratique lorsque l'internaute souhaite mettre en scène un événement, un récit historique ou une thématique et que celui-ci va piocher dans des illustrations ou des documents pour étayer son propos.

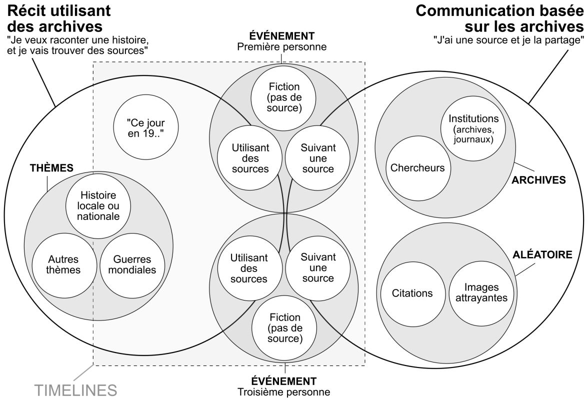

Figure 3 : Typologie des usages de Twitter pour la communication de documents historiques.

Perspectives

Les médias sociaux favorisent-ils une démocratisation et une réappropriation de l'histoire par son public ou sont-ils au contraire un vecteur d'une histoire spectacle décontextualisée ? S'il apparaît de manière évidente que la réponse se situe entre ces deux extrêmes, ou du moins qu'elle varie selon les usages précis, rappelons que nous proposons ici une plongée dans une réalité, quotidienne pour certain et étrangère pour d'autres. Cet état des lieux, en deux parties, quantitative et typologique, doit servir de base à une réflexion plus large sur le rôle des historiens et des institutions patrimoniales dans une société numérique où l'on ne peut lutter contre la dissémination d'images mal référencées et de contenus instrumentalisés. Cerner ces phénomènes, c'est aussi préparer la réplique, rigoureuse, critique et pourquoi pas créative.

New potentials in the digital archives: a participative inquiry into interdisciplinary collaboration in digital historical research at the Wellcome Trust

Alex Green
a.green@wellcome.ac.uk
Wellcome Trust, United Kingdom

Lalita Kapish
l.kaplish@wellcome.ac.uk
Wellcome Trust, United Kingdom

Hannah Walker
h.walker@wellcome.ac.uk
Wellcome Trust, United Kingdom

This paper discusses an exploratory project where a group of university academics, software developers, designers and librarians spent a week analysing a broad selection of the Wellcome Library's digital collections with an aim to explore new ways of conducting collaborative digital history research, identifying and documenting barriers and successes and also pointing to gaps in institutional support infrastructures.

Over the past two decades, significant quantities of cultural heritage have been digitised. Internet Archive has digitised over 20 million items in partnership with libraries and collections around the world. Google has digitised over 25 million books as Google Books. Alongside this the emergent field of digital humanities has sought to take advantage of new opportunities afforded by unprecedented access to collections. Numerous commentators and researchers have, in the words of Hayles (2015), voiced the opinion that "if there is an area of general agreement, it is the transformative potential of digital humanities for the humanities and for academic discourse" (see also Ogilvie, 2016; Alves, 2014).

Wellcome Library, part of the Wellcome Trust, is one of the world's most significant collections relating to health and medicine, with works ranging from posters and paintings to personal archives, printed books and packaging ephemera. Through its digitisation programmes, Wellcome is a major producer of digitised historical material and datasets, with over 40,000 digitised archives, nearly 100,000 digitised monographs and over 10,000 artworks, manuscripts, videos and reports. These have been made freely available under the most liberal licence possible, dependent on the copyright status of the material. In addition, IIIF image services (IIIF Consortium) including standardised image and presentation APIs, along with services for OCR and text search are provided (Chaplin, 2016).

A key aim for Wellcome is to enable new types of research and knowledge production; our mission is 'to improve health for everyone by helping great ideas to thrive' (Wellcome Trust, 2016). One way we seek to do this is through enabling the exploration of cultural and social meanings of health in the past. Digitisation has undoubtedly increased use of our collections significantly and developed a large international audience, with over 50% of researchers accessing content from outside the UK. To better understand the users and usage of our digital collections we have carried out quantitative and qualitative research in collaboration with Prof. Pauline Leonard (Green and Andersen 2016). Our findings showed that beyond increasing access, the nature of collection usage has not changed significantly. The majority of researchers still access works within a single collection, page through digitised works in a linear fashion, make limited use of OCR search and little to no use of APIs. We are not yet seeing Hayle's "transformative potential" (2015) realised. To better understand this, we developed a number of hypotheses and research questions, which we categorise here under four loose umbrellas:

Lean working

In summarising the findings of multiple digital historical studies, Alves has argued that they 'implicitly confirm the efficiency of digital means… but also… that their application is, often, generally associated with expensive projects requiring extensive human resources with diverse skills' (2014). We questioned whether digital research is necessarily expensive or requiring of extensive resource. Drawing inspiration from commercial software development, we asked what is the Minimum Viable Product (Leanstack, 2016); can teams achieve meaningful research relatively inexpensively through an agile approach of iterative investigation and identification of emergent areas of interest rather than pre-defining fixed research questions.

Skills and knowledge

It could be argued that there is a skills or knowledge gap within traditional historical research communities which inhibits conducting digital research. However, we questioned if this was truly a barrier when evidence from citation patterns shows increases in collaborative approaches to digital humanities research (Nyhan and Williams, 2013). We questioned if extending the scope of traditional research teams to include commercial development partners could bring new insights and capabilities.

Crossing collections

Wellcome's digital collections include intensely heterogeneous material along with data sourced from multiple institutions. We questioned whether there are practical or technical barriers to break down divisions between collections and drawing from a range of content. Hitchcock (2013) has argued that 'the lack of flexibility of the available digital tools [has] enabled only the effective utilization and analysis of quantitative sources or sources easily transformed into a quantitative format'. As many of Wellcome's collections are archival and contain large quantities of handwritten and pictorial material, we specifically wanted to explore the possibilities of digital for non-quantitative research, and research which still requires 'close reading' of sources (Van Dijk, 1985).

Quality and consistency

Areas of enquiry in this umbrella included whether our digital collection is suitable in its scale and scope, and the quality and consistency of OCR and collection metadata. We also questioned if we we had the right kind of web services available and their usability for individuals with different levels of experience.

To explore and better understand these questions we designed an experimental approach, adapting a concept becoming familiar to cultural institutions – the 'hack day' – and extending it out into a week-long intensive R&D project, where small teams led by a mix of independent and academic researchers would work collaboratively to explore the Wellcome Library digital collections. Our participants included research staff from several UK universities, librarians and archivists, commercial designers and software developers. Through careful screening of participants, we selected researchers with shared enthusiasm for, but variable experience of digital historical research. This choice was deliberate in order to focus in on barriers relating to experience, skills and technical feasibility without confounding these variables with any reluctance to use digital methods. However, the enthusiasm for digital methods in the historical community is an important question and undoubtedly merits further investigation. Research areas were open-ended, with a focus on experimentation rather than production of finished work. However, we did agree broad areas, including handwritten records from a private asylum, 5000 Medical Officer of Health reports covering London from 1848-1972, 6,600 issues of the trade journal Chemist and Druggist and the 79,000 books digitised by the UK-MHL project (Wellcome Library, 2016).

Drawing from approaches of participative and cooperative inquiry (Reason and Bradbury, 2008) we embedded Wellcome staff in mixed teams of academic staff, developers and designers, positioning the teams as researchers of the collections, participants in a broader experiment of research production and observers and documenters of the experiment itself. We encouraged self-documentation by teams through use of project boards, blogs and wikis, conducted individual interviews with participants throughout the process and held daily reviews and a plenary session to discuss progress and reflect on the experiment.

During the week we produced multiple tools and visualisations, and also historical findings. These are documented on the project blog, along with the processes each team went through. This clearly demonstrated the potential of the collections, but also the barriers to working with them. Interestingly, the project using digitised archival material without OCR was one of the most successful – partly due to the synergy of the team members, but also the clarity of the challenge for the material. Two of the five projects seeded in the week continue to be developed, and we are continuing to provide support to the researchers leading them.

Feedback from participants in the project identified particularly the benefits of working in teams with mixed skill-sets. Developers and library staff gained from acquiring greater understanding of research processes and interests, while researchers gained access to technical skills, and exposure to a different approach to digital working. One participant remarked: 'I found working with other people, from a variety of different backgrounds, really generative – both for thinking about why people who do different kinds of work approach digital resources in different ways, and for thinking about my own research along new lines.'

The web services we provide for programmatic access to digital collections were identified as a particular barrier during the week. While the images and bibliographic metadata for our collections are exposed through an international standard, the Image Interoperability Framework (IIIF), this proved conceptually complex for developers to quickly prototype with, requiring combining and processing multiple JSON responses to access digital items. Adding further complexity to this, our collection OCR is available primarily through ALTO XML (Library of Congress, 2016) which our developers found challenging to process at scale.

As cultural heritage institution and a research funder, we are continuing to unpack the implications of the findings. As a library, we found great value in co-production with research users so will be repeating a similar annual event, investigating different aspects of our collections. We have also identified particular issues related to the usability of our collections and added these to our development roadmap. As a funder we are considering options for increasing innovation by seeding early stage research through similar collaborative processes. To take this forward we will be running a series of pilot events through our interdisciplinary research residency, The Hub.

Dazzle them with Baffles: Gauging Attitudes toward Digital Fabrication in an Online Musicians' Community

Brian Greenspan
brian.greenspan@carleton.ca
Carleton University, Canada

This paper presents a project, currently underway, that combines 3D fabrication and digital audio processing with text mining and sentiment analysis to gauge attitudes toward digital fabrication processes (and maker culture more generally) among a large online community of musicians.

In the last two years, traditional musical instrument manufacturing materials have been joined by laser-sintered plastics and photopolymer resins, as new Additive Manufacturing techniques have been employed either to replicate vintage instrument parts, or redesign them altogether. In no case, however, have digital fabrication methods managed to entirely displace artisanal tradition.

This study explores how digital fabrication has been negotiated by one large and active online musician's community that values artistry, craft, and industrial history alike. Using low-end desktop 3D fabrication methods with open-source software, I am reproducing a line of replica instrument parts based on vintage originals. Once all reproductions are complete, I plan to engage a professional musician to test-play the printed replicas, and compare them with their original vintage models. These tests will be recorded using audio freeware, and shared with members of a select online musician's community, in order to determine whether they distinguish my 3D-prints from their original models.

My aim is less to determine whether these replicas are in fact morphologically and sonically identical to their period models than to determine how 3D digital fabrication is received by musicians strongly devoted to vintage equipment and artisanal craft. Using the Python Natural Language Toolkit (NLTK 3.0) with a naïve Bayes classifier trained on a valenced wordlist (e.g. AFINN), I will conduct sentiment analyses of the online forum to gauge how the community of musicians responds to the introduction of new manufacturing techniques that are neither industrial nor conventionally artisanal.

Ultimately, this project addresses the "emergence" of digital humanities (Jones 2013) into artisanal practices as a sign of our contemporary "post-digital" condition, under which we need "no longer talk about digital versus analog but instead about modulations of the digital or different intensities of the computational" (Berry 2014). By engaging one active and prominent community of analog musicians in a discussion of digital fabrication, I hope to use their insights into the materiality of music production to address questions crucial to maker epistemology, such as: "For which methodologies do tactility and texture especially matter?," and "When is scholarly communication most persuasive off the screen?" (Sayers 2015).

Introduction

This paper reports on work in progress aimed at facilitating the creation, sharing, linking, and analysis of data about the movement of people, ideas, cultural practices, and commodities between places, over the course of history. Products of the Linked Places project include: conceptual and logical models for historical routes; a temporal extension of the popular GeoJSON data format, called GeoJSON-T; several varied exemplar data sets converted to GeoJSON-T format; prototype web software for browsing and visualizing that data; and Python scripts to convert data between CSV, GeoJSON-T, and RDF compatible with the Pelagios Gazetteer Interconnection Format. Substantial interim work products are shared in the Linked Places and GeoJSON-T GitHub repositories and have been reported in some detail in two blog posts (1, 2) .

Motivation

A growing number of historical gazetteers are being developed in the course of digital humanities research projects (Berman, Mostern & Southall, 2016). Their spatial temporal coverage is typically limited to a particular area and period due to factors of scholarly quality, cost, and relevance to a given project. Coverage extents do vary considerably, from a single city for a few generations to a region for several centuries. With few exceptions, these gazetteers are unpublished as such; instead they are spatial tables contained within, and integral to, the larger project data store.

Because historical gazetteers are difficult and time-consuming to produce, it is vital they be published, when possible, in a way that permits linking them—an activity that the Pelagios project has made great strides in facilitating. An emergent network of specialized gazetteers holds terrific promise, not only for re-use, but ultimately as a distributed, increasingly comprehensive geographical (i.e. spatial-temporal) index to linked data from numerous domains, including history, archaeology, literary studies, philology, and several of the social sciences. The focus of such an index, and encyclopedic applications it enables, will be on individual places, typically at the scales of cities and points of interest.

Such systems are highly desirable, but given a large volume of data about individual places we can also begin harvesting, creating, and sharing data about the connections between them. We should be able to ask of historical gazetteers: What journeys and historical routes has a given place been a waypoint on? And, what flows of people, ideas, and commodities has it been a source or sink for?

But the Linked Places and GeoJSON-T projects have been undertaken with an even larger, “moonshot” vision in mind: a system allowing scholars and the general public to visualize and analyze the emergence, growth and spread of human settlements, their changing attributes, and the dynamic connections between them, including the diffusion of technologies and cultural practices.

To realize these ideas, we need a) lots of data, and b) methods and means for merging or linking them. In some respects, we are starting from scratch; data about historical movement is sparse and stored in disparate forms. Much of it will be newly generated, for example by parsing texts, transforming tabular records, or digitally tracing lines on historical maps. Merging and linking operations will require that the form of data from different sources (or abbreviated catalogues thereof) be either standardized (in the case of merging), or similar enough that automated alignment is feasible.

The majority of works on geographic networks concerns physical media like roads and rail, whereas movement data is eventive. Geographers have modeled migration flows and disease diffusion for several decades, providing theoretical bases for their analysis that are outside our present scope. An overview of that work is found in (Lowe & Moryadas 1975). An excellent and more recent work on mobility and geographic movement is Tim Cresswell’s “On the Move” (2006). We are not aware of any efforts to model data for historical routes computationally, however the core abstraction we build upon is the traditional graph/network model of nodes and edges credited to 18th century work of Euler (Biggs, et al 1986).

A Modeling Pattern

Data modeling is as much an art as a science (Simsion & Witt 2004), but some core best practices are well-known. A typical first step is establishing what entities are to be represented, what their essential attributes are, and what relationships obtain between them (cf. Chen, 1976). This step is often best accomplished collaboratively, in an iterative process undertaken by domain experts. Our results were immediately published to blog posts and relevant listservs, and the resulting input was useful in refining the model.

When the modeling context is an individual research project, it hardly matters what names are given those entities and relationships—only that the data store's internal logic be sound and well understood by project members. But if, as in this case, the system will accommodate data from many sources or be accessed by others, we need to find broad agreement on a conceptual model and a vocabulary for its constituents between as many prospective participants as possible—that is, to describe the ontology of the research domain. Although much ontology engineering of this sort has involved comprehensive high-level ontologies such as the CIDOC-CRM , the development and implementation of small ontology design patterns (ODP) has been gaining favor since the introduction of that paradigm by Aldo Gangemi (2005). Such patterns, by any name, are "reusable successful solutions to a recurrent modeling problem" (definition provided by the Association for Ontology Design & Patterns (ODPA)) which can be used alone or assembled in modular fashion for larger requirements. Examples include patterns for "Place," "Event," "Participation," and "Region."

And so the first step taken in the Linked Places project has been to develop an ontology design pattern for the historical movement of something between two or more places over some physical channel, either for some time during or throughout a timespan. The pattern, visualized in Figure 1, comprises the following conceptual understandings:

A route describes an attestation of one or more occurrences of the movement of something (e.g. people, commodities, information) between two or more places, either for some time during or throughout a time_period. Routes are composed of one or more segment, each of which is composed of two places and a path (corresponding to nodes and edges in network parlance), the locations and temporal attributes for which may be unknown or unspecified. Movement between places occurred upon ways (the term used by OpenStreetMap) —physical channels such as roads, rivers, canals, railways, footpaths, and sea lanes—and may have been directional.

The three types of routes considered here are journeys, flows, and historical_routes:

A journey is the record of a specific instance of travel by one or more individuals. Examples include: the 7th century pilgrimage of the Buddhist monk Xuanzang across China and India; the first voyage of Captain James Cook, between 1768 and 1771.

A flow is the record of the movement of something (commodities, people, ideas) between two places, aggregated as a magnitude over a period of time. Examples include: the transport of captive Africans between West Africa and Bahia in the 17th century; letters between certain correspondents in Paris and Prague in the 18th century; a source network of late Neolithic obsidian artifacts and known source locations on the Anatolian Plateau.

A historical_route asserts a single or composite named course of travel between places, taken repeatedly by unspecified individuals over time, usually for purposes of commerce. Examples include the Silk Road and the Amber Routes. Some correspond with named roads, for instance the Via Salaria in Italy is both a way and a historical_route. Additional axioms indicated by the relations and cardinality expressions (e.g. 0…*) in Figure 1 include:

- All routes are sourced, normally to textual or cartographic documents
- The way for a segment (its physical path described by a geometry) may be known and represented, unknown, or ignored (Segments with unspecified ways will typically be visualized as a line or arc)
- Each segment has one or more temporal attribute ("when"), which can be a time_period, (possibly named) or a sequence (e.g. after segment n)
- Routes and their component segments can have any number of attributes (properties), dependent upon data sources and project requirements

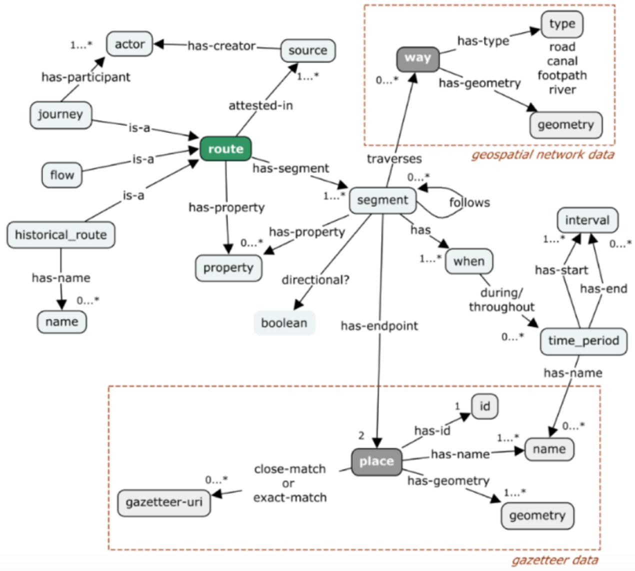

Figure 1. A conceptual model for historical movement (routes)

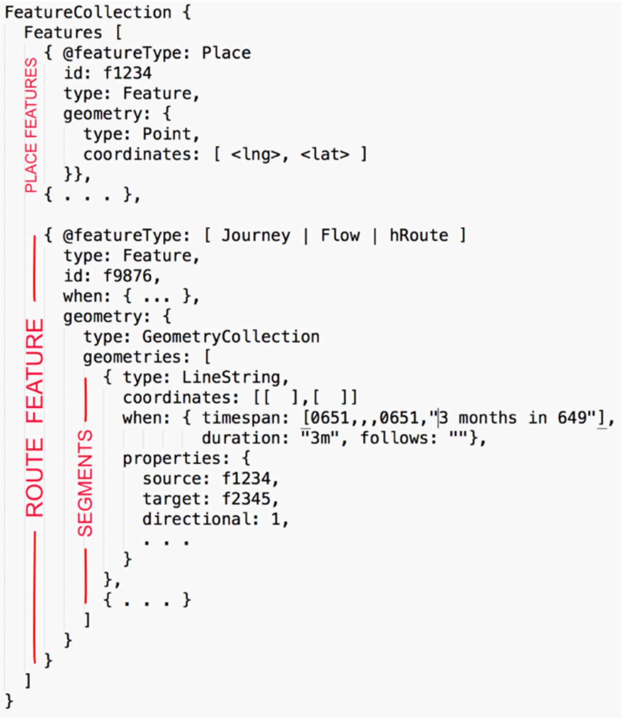
The ontology pattern we introduce here is specialized, as compared to high level ontologies like CIDOC-CRM. We have not yet mapped our distinctive entities (route, journey, flow, historical_route, segment, when) to existing ontologies. The term place is commonly found, but usually is synonymous with location; the sense we are adopting is that of the Pleiades gazetteer, but is not in a published ontology that we're aware of. In any case, we feel it is best to first lay down a logically coherent set of terms and at a later date attempt to align them with other ontologies.

Formats

The route ODP has informed our development and implementation of recommended standard data formats. It turns out all three types of routes can be effectively described in GeoJSON-T, an extended version of GeoJSON, the widely-used format for representing geographic FeatureCollections. A FeatureCollection of routes will include both Place and Route features. Route segments are articulated as an array of one or more geometries in a route's GeometryCollection. GeoJSON-T allows optional "when" objects, both for each feature at the same level as its geometry object and for segment geometries (Figure 2). Features and segments have certain required properties as shown, and can have unlimited project-specific properties.



```
FeatureCollection {
  Features [
    { @featureType: Place
      id: f1234
      type: Feature,
      geometry: {
        type: Point,
        coordinates: [ <lng>, <lat> ]
      }},
    { . . . },

    { @featureType: [ Journey | Flow | hRoute ]
      type: Feature,
      id: f9876,
      when: { ... },
      geometry: {
        type: GeometryCollection
        geometries: [
          { type: LineString,
            coordinates: [[  ],[  ]]
            when: { timespan: [0651,,,0651,"3 months in 649"],
                    duration: "3m", follows: ""},
            properties: {
              source: f1234,
              target: f2345,
              directional: 1,
              . . .
            }
          },
          { . . . }
        ]
      }
    }
  ]
}
```

Figure 2. GeoJSON-T applied to route data

Data

To date, seven exemplar datasets have been converted from a typical CSV format to GeoJSON-T, using a newly developed Python program. Three are for journeys: two by individuals (a 7th century pilgrimage and a modern circumnavigation), the third by 840 Venetian ship convoys in the 13-15th centuries. Another dataset aggregates those ship journeys as flows having magnitudes of journeys and ships. The last three are historical_routes: the Roman era itinerary of the Vicarello Beakers, the route system between courier stations in Ming Dynasty China, and a large set of "Old World" trade and pilgrimage routes .

Software

The widespread adoption of GeoJSON has demonstrated that for a data format to be useful, there must be software with visualization and analysis capabilities that supports it. Accordingly, an essential element of the Linked Places project is development of proof of concept web software to render GeoJSON-T data, for both routes and places alone, to a map and timeline together. The development of that software is ongoing, and publicly available. (Figure 3).

Introducción

Encontrar relaciones entre los encabezamientos que se asignan a una obra monográfica es un problema histórico en el ámbito de búsqueda y recuperación de información. Por un lado, los documentos rara vez pueden ser representados con un solo tema; por otro, el número de temas que se puede asignar a una obra es virtualmente infinito (Green, 2001). En la intersección de las Humanidades Digitales y la Bibliotecología han existido diversos esfuerzos por mejorar la calidad de las ontologías de estos temas (Nurmikko-Fuller et al, 2016), su evaluación (Harper, 2016) y visualización (Duguid, 2015). Sin embargo, a nuestro conocimiento, no se han hecho estudios que aprovechen métodos innovadores para indagar relaciones entre los encabezamientos de materia. En esta comunicación breve, presentamos los resultados preliminares de un primer acercamiento al tema, que aprovecha el área de especialidad de cada participante del equipo --humanidades digitales, ciencia de datos y bibliotecas-- para analizar 249,899 registros de una de las colecciones más importantes de Ciencias Sociales y Humanidades de América Latina: la del catálogo de la Biblioteca Daniel Cosío Villegas de El Colegio de México.

Metodología

A través del portal de analíticas del Grupo Ex Libris, se extrajeron los encabezamientos de materia de todos los 249,899 registros de libros de la colección de la Biblioteca Daniel Cosío Villegas. Los encabezamientos de materia fueron subdivididos a su vez en tres niveles a partir de los subencabezamientos, sin distinguir entre sus tipos –geográficos, cronológicos y de forma (ver Salta et al., 2015)– sino sólo tomando en cuenta su posición (primer subencabezamiento, segundo, etcétera). Por ejemplo, México--Historia--1821-1861 fue dividido en: México, Historia, 1821-1861.
Se estudió la relación entre temas utilizando técnicas de minería de reglas de asociación. Estas procuran descubrir implicaciones de la forma $I \rightarrow i$ donde I es un conjunto de objetos y i es un objeto en particular, ambos tomados de un universo de objetos, en este caso temas. El soporte de I se define como el número de registros para los cuales I es subconjunto. La confianza se define como el soporte de $I \cup i$ entre el soporte de I (Leskovec, 2010).

Se debe notar que la frecuencia de los temas asociados a los registros es sumamente baja como se puede observar en la Tabla 1, lo cual puede deberse a que, tratándose de una biblioteca especializada en ciencias sociales y humanidades los temas que se asignan son muy específicos, a fin de que el usuario especializado pueda encontrar lo que realmente le sirve.

	Percentiles					
Tema	25%	50%	75%	85%	95%	99%
1	1	1	3	5	22	129
2	1	1	3	6	27	219
3	1	1	3	6	28	170

Tabla 1

Asimismo, es de notar que 231,052 (92.45%) de los registros tienen un encabezamiento de materia; 152,414 (treinta por ciento menos) llega a tener dos encabezamientos de materia y sólo 29.89% tuvo tres. Por este motivo, los encabezamientos se concatenaron verticalmente para observar indistintamente las relaciones entre éstos. Se utilizó el algoritmo *a priori* y la elección de los umbrales se llevó a cabo de manera manual; se generaron 13 conjuntos de reglas de asociación con variaciones en los umbrales de confianza y soporte. Cada uno de estos conjuntos de reglas de asociación induce un grafo que se puede visualizar y explorar como se muestra más adelante. Umbrales demasiado permisivos inducen redes que tienen demasiadas relaciones como para poderse explorar manualmente y umbrales demasiado restrictivos inducen redes que no tienen suficientes relaciones como para poder decir algo interesante sobre la estructura de los datos en su totalidad. Finalmente se eligió una red que presenta un balance entre cantidad de información e interpretabilidad. El 'soporte' mínimo fue de 0.0001 (ver Gráfico 1) y la 'confianza' mínima de 0.4 (ver Gráfico 2) y la matriz de incidencia derivada de las reglas encontradas se utilizó para generar un grafo para la exploración visual del conjunto de asociaciones descubiertas. Para crear esta versión gráfica utilizamos la exportación de R a Gephi (Yon and Yon, 2015), la 'confianza' como un peso para los vértices y Fruchterman Reingold (1991) como algoritmo para el diseño. Dimos color a los nodos de acuerdo con su modularidad, es decir, de acuerdo a las "comunidades" de nodos que se crean por la fuerza de sus relaciones (Blondel et al, 2008). La alta modularidad de la red prueba lo conectados que están los nodos en sus grupos y lo desconectados que están de nodos fuera de su red.

Resultados

Como hemos mencionado antes, los encabezamientos fueron divididos en los subencabezamientos que los anidan. Retomando el ejemplo anterior: "México--Historia--1821-1861" fue codificado como:

- Subject 1.1 - México
- Subject 1.2 - Historia
- Subject 1.3 - 1821-186

Este modelado de los datos, fue pensado para permitir una cierta exploración "gramática" de la asignación temática. Es decir, que permitiera ver qué niveles "sintácticos" se relacionan en qué orden con otros niveles. En números, la red tiene 394 nodos (subencabezamientos) y 339 vértices (asociaciones). De los nodos, 203 son del primer nivel, 109 del segundo, 33 de la combinación de un encabezamiento del primer nivel con el tercero, y cuatro de la combinación del primer nivel con el cuarto. El total asociaciones o reglas de implicación (si encabezamiento I aparece también i) fue de 339. De éstas la mayoría ocurre sólo en 25 registros, es decir, tuvieron un soporte bajo (ver Gráfico 1). Sin embargo, esto no es tan poco considerando lo que hemos dicho antes de la naturaleza especializada de esta biblioteca. Por otro lado, las confianzas observadas presentan una distribución menos concentrada que la de los soportes (ver Gráfico 2).

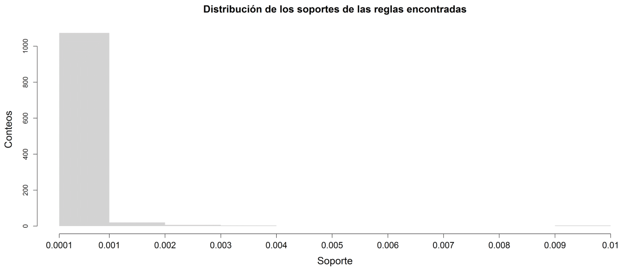

Gráfico 1

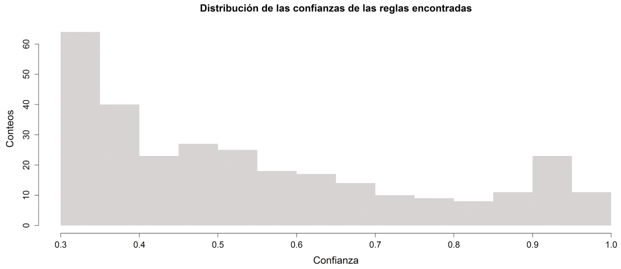

Gráfico 2

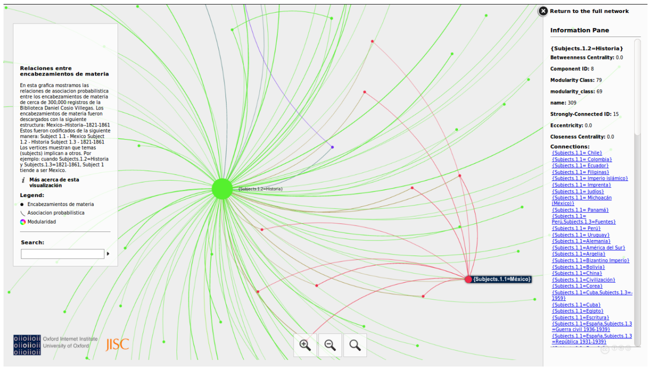
De la red de grafo interactiva que obtuvimos con el uso de Gephi y el *plug-in* de Sigma.js, pudimos identificar que el nodo con mayores asociaciones o reglas es 'Historia' en su posición como "Subject 1.2" y que entre sus asociaciones existen dos nodos de distinta modularidad y nivel (ambos "Subject 1.1"): 'México' (ver Imagen 1) y 'España' (ver Imagen 2).



Relaciones entre encabezamientos de materia

En esta grafica mostramos las relaciones de asociacion probabilistica entre los encabezamientos de materia de cerca de 300,000 registros de la Biblioteca Daniel Cosio Villegas. Los encabezamientos de materia fueron descargados con la siguiente estructura: Mexico--Historia--1821-1861 Estos fueron codificados de la siguiente manera: Subject 1.1 - Mexico Subject 1.2 - HIstoria Subject 1.3 - 1821-1861 Los vertices muestran que temas (subjects) implican a otros. Por ejemplo: cuando Subjects.1.2=Historia y Subjects.1.3=1821-1861, Subject 1 tiende a ser Mexico.

En resumen, este tipo de exploración permite al usuario familiarizarse con las reglas "gramaticales" de la asignación temática pues puede "ver" tanto los niveles "sintácticos" de los temas como las formas en que se relaciona con otros, además de que incluye un botón de búsqueda de encabezamientos que permite interactuar de manera directa con el grafo (disponible en linea).

Reflexión final

Nosotros, como lo sugieren Nurmikko-Fuller et al., estamos conscientes de que si las bibliotecas quieren dar acceso a recursos de información relevantes para nuevas áreas de investigación, deben evolucionar a métodos más sofisticados y semánticos de asignación temática para proporcionar nuevos puntos de acceso que correspondan más al lenguaje natural y que permitan identificar las relaciones temáticas con mayor claridad.

Sin embargo, en lo que este paso puede ser dado en México y Latinoamérica, creemos que el uso de herramientas y métodos de las humanidades digitales pueden ayudar a analizar los datos generados en la organización de la información e incluso útil para la formación del catalogador, que aprende a asignar-elaborar los temas y con esta herramienta podría tener un acceso visual a la "sintaxis temática" de ciertos términos. En este mismo sentido, un acercamiento así, podría ser usado como elemento pedagógico de los cursos de investigación documental en el que los estudiantes deben aprender a familiarizarse con los lenguajes controlados. Otra aplicación de este trabajo, podría ser en la evaluación de colecciones para determinar las fortalezas y carencias temáticas, de acuerdo con la especialidad que la biblioteca declara. Análisis más detenidos pueden ayudarnos a determinar la representación cronológica, autoral, lingüística o geográfica de un acervo. En fin, consideramos que al continuar el análisis y desarrollo de este proyecto podremos aportar otro tipo de metodología no sólo para evaluar las colecciones sino para acercarse a ellas.

Introduction

By publishing his "Graphische Litteratur-Tafel" [Graphic Literature Table] in 1890, German writer Cäsar Flaischlen (1864–1920) aimed to portray the influences of foreign literatures on the development of German literature. Flaischlen produced a 58×86.5-cm poster, depicting German Literature as a stream with feeder rivers from mainly other European (national) literatures. His chart covers the development of German literature from its beginnings with various sources, forming two parallel rivers subsumed under the concepts of "Volkspoesie" [folk poetry] and "Kunstpoesie" [artistic poetry], intertwining and finally converging into one broad stream of German literature. The broadening river reaches from the beginnings of German literature at around 750 to Flaischlen's present, the 1890s.

Cäsar Flaischlen was not much of a practising literary scholar, nor an academic. After completing a dissertation around the same time as he published his "Graphische Litteratur-Tafel", he left academia to continue writing (dialect) poetry, novels and plays, while working as an editor for arts and literary magazines.

The flowchart, although being a flamboyantly beautiful one, is not as novel and unique, as one might think: It follows a long tradition of visualising developments along the axis of time (cf. Rosenberg and Grafton, 2010) and follows the patterns of the highly influential graphical visualisation of history, "Strom der Zeiten", published in 1804 by Austrian historiographer Friedrich Strass.

Being a representative of positive thinking of his time, Flaischlen builds on the time-stream metaphor, but strives to connect this idea with the exact sciences. Although he does not mention the sources used for compiling his chart, this early visualisation of literary history relies on some kind of data, even if, in his 8-column preface, Flaischlen deemphasises the connection between quantitative evidence and visualisation: For example, he points at the fact that the breadth of the stream was not calculated mathematically ("nicht mathematisch berechnet"), but nonetheless, there seems to be a connection between the selection and especially placement and typographical styling of influencing and influenced authors' names on the chart.

As this example illustrates, the information density of the chart is enormously high:

Flaischlen includes names of authors, texts, literary groups and schools and uses typography (font, font size, font decoration, colour), symbols (circles in various sizes, Roman and Latin numerals), shading of creeks and rivers and language-information to visualise the information.

Our digital edition of Cäsar Flaischlen's "Graphische Litteratur-Tafel" aims to make digitally available the information deeply encoded in the table. Extracted data points are presented in two shapes: on an easily navigable website and in a machine-readable version.

For this reason, the preface was OCRed and encoded in XML according to the TEI guidelines. The flowchart was scanned and transcribed following the recommendations on "Advanced Uses of <surface> and <zone>" (cf. TEI guidelines) to also record spatial information. Coordinates of authors and texts were calculated by help of the GIMP Image-Map editor, then linked to corresponding authority files (VIAF, GND, and Wikidata). The cartographic inventory of the map is marked-up and made searchable by using CSS as a descriptive language for capturing the rendering within TEI @style attributes.

The TEI data is provided via a GitHub repository and processed via XSLT for displaying the flowchart as a web page.

The interface combines the three separate sections of Flaischlen's map and allows for searches via an index. For presentation on the web, the sections were stitched and put together into one giant river. In an analogue format, the river would be almost three meters long, now one can scroll seamlessly down and up the river online. A prototype of the edition is available on the project website.

Flaischlen's map is not only an inspiring prototype for contemporary attempts to visualise data of literary history with "graphs, maps and trees" (Moretti, 2007), but also challenges the development and encoding of older graphical representations of (literary) history on a methodological level.

Flaischlen's 1890 visualisation "Graphische Litteratur-Tafel" deserves further recognition and our online edition could serve as a test case for other – so far unknown and/or not edited – flowcharts of literary history.

German History–*Digital*: A Platform for Transnational Historical Knowledge Co-creation

The German Historical Institute Washington (GHI) is in the development phase of German History-*Digital* (GH-D), a transatlantic digital initiative to meet the scholarly needs of historians and their students facing new historiographical and technological challenges. In the proposed paper we will discuss the research goals, methodology, prototyping, and development strategy of GH-D as infrastructure to facilitate transnational historical knowledge co-creation for the large community of researchers and students already relying on digital resources of the GHI and for the growing constituency of citizen scholars.

Despite its great progress, the digital humanities have yet to broadly impact research in German history. The past ten years have witnessed the proliferation of online resources relevant to the field, yet these materials largely remain siloed in different systems, with material difficult to discover or gather by scientists into corpora. Historians themselves are today increasingly producing scholarly content in digital form, but there remains no established criteria for the peer review of digital publications and projects. This ultimately limits the time and energy the research community is willing to invest into digital knowledge production and thus confines the Digital Humanities' potential for growth.

Preservation and future access to digital materials is also of critical importance, particularly in the North American context where continental and national digital research infrastructures for digital humanities are lacking; there is currently no equivalent to European research infrastructures like CLARIN or DARIAH. In respect to scientific methodology, there is growing expectation that historians take advantage of an abundance of digital tools, yet there remains insufficient integration between tools for historical research and between tool sets and online resources. The importance of citizen science and knowledge co-creation for the future of historical research is also recognized, yet for these developments to occur there must exist beyond e-lists and other legacy communication technologies scholarly environments for the creation of area-specific research communities, scientific collaboration, and public engagement.

The planning for GH-D involved surveying over four hundred scholars of the many thousands already using digital resources produced by the GHI. The most prominent of these resources is the digital source collection „German History in Documents and Images" (GHDI), which is widely used at universities in the German and English speaking world. Launched in 2003 and currently undergoing a technical and conceptual revamp in conjunction with GH-D, GHDI currently includes thousands of pages of English-language translations of German historical texts, as well as images and maps, all of which are accessed by approximately 5,000 visitors per day. Our planning for GH-D also continues to involve consultations and workshops with expert historians and digital humanists, and the establishment of partnerships with institutions and major initiatives that share our concern for the future of history in the digital age.

The German History-*Digital* platform addresses needs of digital scholarship through five goals and integrated work packages concerted to these goals: *discovery, analysis, production, preservation, and community*.

We believe GH-D provides a new model in the design and development of a social knowledge creation environment for humanities-oriented research. The proposed paper will be structured by providing technical and theoretical explication of the core work packages within relevant DH contexts.

Discovery

A major challenge facing scholarship online is that a vast number of digital resources, particularly those produced independently by scholars or smaller institutions, do not have standardized metadata records and are not accessible via any centralized scientific index. GH-D involves development of a peer-reviewed index of scholarly digital objects using Dublin Core (DC) and CLARIN's Component MetaData Infrastructure (CMDI) standards via a customized Blacklight technology stack.

Preservation

For scholars developing historical digital projects in North America, there exists no inter-institutional infrastructure for preserving their data and making it openly available. With consultative and knowledge support from CLARIN-D, which is part of the European research infrastructure CLARIN, the GH-D project will establish the first portal to CLARIN in North America at GHI Washington. Central to this process is the implementation of a repository that allows a sustainable storage of the content and the inclusion in a digital environment to ease access, search and an interoperable data formats. The content of the repository and the repository itself adheres to international, widely accepted and supported standards. The high quality of the technical solution and the conformance to standards is secured by an independent organization that gives out the Data Seal of Approval. Like the majority of CLARIN centres in Germany, the GH-D will use a Fedora Commons repository with Apache Solr for indexing and search, components included in the technology stack of Project Hydra. Our partnership with CLARIN promotes open access, open science and knowledge co-creation in the North American context, and is an important component in the overall digital humanities research strategy of the GHI. As an institute of the Max Weber Stiftung, we are also in partnership with DARIAH-DE and arrangements have been made for DARIAH to provide long term preservation of GHI digital projects in their entirety, beginning with the first edition of German History in Documents and Images. Beginning with the GHDI project, GH-D is part of the DARIAH-DE Service Lifecycle program.

Production and Publication

As a knowledge co-creation platform, GH-D will bring together editors, researchers and citizen scientists in the development of innovative online projects. Three such pilot projects are currently in development based on customization, including support for TEI, and internationalization of the Scalar 2.0 platform. GH-D is using Scalar 2.0 for the baseline content management system, particularly on account of its interface features, support for RDF, connectivity to external repositories, Dublin Core support. Hypothes.is integration, and its multiple path navigation system.

Analysis

Historians are increasingly using digital humanities tools to analyze data and express their research findings. A further advantage of storing digital objects within the CLARIN repository the GHI wants to built up is that the full range of corpus linguistic analytic tools of CLARIN can be applied by scientists to GHI textual content. During the first phase of the project we also look to prototyping connectivity to PARTHENOS, another major European infrastructure project. PARTHENOS integrates within a virtual research environment (VRE) access to data from numerous national archives and a broad set of digital tools which can be chained together into analytic processing workflows.

Community

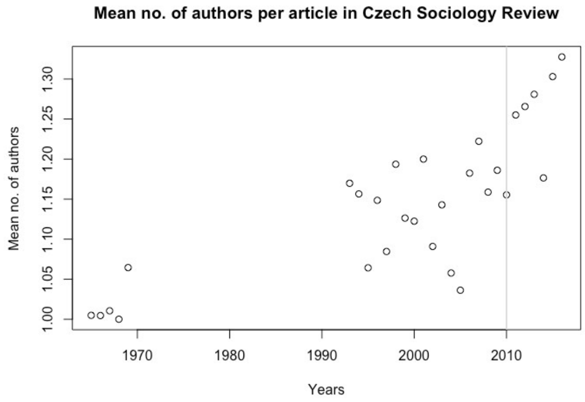
The GH-D platform integrates blog aggregation, an advanced discussion system, community-oriented tools, and social media, to facilitate collaborative knowledge communities and open research. This is a pioneering aspect of our project that will investigate the adoption by historians of social and community digital tools in their research activities. We also intend to make use of the unique role the GHI plays as a hub of transatlantic scholarly dialogue and a major knot within an international network of historians in order to facilitate connections between different scholarly communities.

Topics and genre changes in Czech sociological articles

Radim Hládik
radim.hladik@fulbrightmail.org
Czech Academy of Sciences, Czech Republic

Introduction

Since Kuhn's distinction between "textbook" science and "article" science, studies of scientific texts have established the social nature of academic writing. Analysis of scientific texts can yield epistemological, disciplinary, and historical insights. These texts are the arena in which knowledge claims are raised (Myers 1985), trials of strength held (Latour 1987), intradisciplinary boundaries drawn (Wolfe 1990), disciplinary histories traced (Bazerman 1988). Genres of scientific texts have thus been shown as socially enacted structures (Berkenkotter, Huckin, Ackerman 1994) rather than as transparent styles. Despite their many merits, the hitherto available empirical studies on scientific writing have been constrained by either a focus on early history (such as the original Philosophical Transactions of the Royal Society) or reductive sampling for traditional content analysis that allow researchers to grasp the otherwise immense textual data. Approaches inspired by digital humanities approaches offer new possibilities of studying disciplinary formations, as was demonstrated by Goldstone and Underwood (2014) in their distant reading of literary studies texts. This paper follows suit in reporting the results of applying digital humanities methods of text analysis to the corpus of research articles in sociology, specifically, in Czech Sociological Review. Writing in wide-scope disciplines, such as sociology, is of particular interest because it embodies the conflict between literature and the notion of social science (Lepenies 1988). Sociology has been revealed as a discipline of two writing cultures, monographic and journal (Wolfe 1990). The writing in sociology is also oscillating between the aspiration to the positivist ideal of science (Leenhardt 1992) and the acceptance of diverse styles (Agger 2002). Abbot and Barman (1997) have concluded, on the basis of sequence comparison, that research articles in sociology lack "rhetorical rigidity". The discipline thus offers a particularly opportune resource for the analysis of genre and topical variations. Czech Sociological Review was chosen as an example of a "core" journal in the country. As Oromaner (2008) demonstrated, "core journals" in sociology have tendency to become central to the discipline's "intellectual integration". Thus the results of the analysis can be taken as indicative of the mainstream tendencies in Czech sociology. The focus on the Czech sociology has the additional advantage of representing a interesting example of a discipline undergoing substantial transformation in the wake of academic and wider societal changes that came about with the fall of the Communist Party regimes in 1989. Also, the journal offers open access to its content. The data for the analysis were scrapped from the journal's website in September 2016 and the resulting data set contains 3483 articles. A preliminary exploration of metadata revealed noteworthy patterns around the year in which a new policy for science evaluation had been introduced (cf. the figure).



The data collection and analysis is carried out using R language. Besides crude measures of the corpus, the paper will also report the analysis of the textual data, using text mining techniques to comment on the issues that have been raised in the available literature. Topic modeling through LDA model will be used to assess the topical changes across time. Annual frequencies of particular words will be used as indices of changes of the transforming disciplines (this includes, especially, the words relating contemporary sociology to its "communist" variety, such as references to Marx or "communism"). Multidimensional scaling will then be employed to reveal term clustering around further keywords that arguably important in sociology. Quantitative bias, or a lack of thereof, will be measured by the presence of numbers. The overall purpose of the analysis is to address the questions raised in pre-existing literature using the specific example of a Czech social science discipline and to demonstrate the usefulness of text mining techniques in the analysis of scientific writing.

Christoph Schommer
christoph.schommer@uni.lu
ILIAS Lab, University of Luxembourg, Luxembourg

Historical maps are progressively digitized and added to the inventory of digital libraries. Beside their value as historical objects, such maps are an important source of information for researchers in various scientific disciplines. This ranges from the actual history of cartography and general history to the geographic and social sciences. However, for most of these digital libraries, the available metadata include only limited information about the content of the maps, for example author, title, size, and/or creation date.

Whereas given information extraction methods are designed for modern maps and mostly limited to certain types that share similar graphical features, there exist a limited number of tools that rely on a manual recording to visualize certain properties such as distortions as well as support a content-based querying. Examples concern the development of places over time, toponym changes over time, and the identification of the position of places (historical map vs. modern map). This also applies to place markers and text labels, which contain inherent information and so the annotation and geo-referencing of place markers is a crucial task, which can be supported with computer based tools (Budig and Dijk, 2015, Höhn et al., 2013, Shaw and Bajcsy, 2011, Simon et al., 2011).

As already presented in previous contributions (Höhn and Schommer, 2016, Höhn et al., 2013), the Referencing and Annotation Tool RAT supports an identification of place markers in digitized historical maps. RAT facilitates a geo-referencing by suggesting the most likely modern places based on an estimated mapping. The suggestions can be constrained by additional filters, for example by applying a phonetic search (with the Kölner Phonetik) to places, which sound similar to names given on the map. This allows an identification of modern places, whose historic name has changed over time but where its name still is close. RAT performs a template matching algorithm based on the normalized cross-correlation for the identification of place markers. If there are colored place markers in a map, a color segmentation methodology can be used to detect these markers. With respect to the geo-referencing, RAT uses the implemented phonetic search and an estimation of the positions of the place markers.

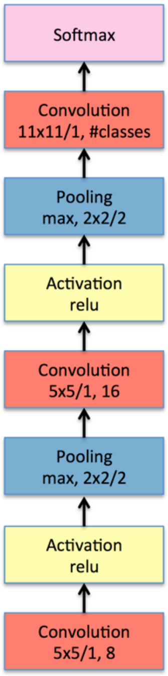

Figure 1. Architecture of the Convolutional Neural Network, which shows the operations used for processing the image

In addition to the original template-based place marker recognition algorithm, we integrated a place marker recognition algorithm based on convolutional neural networks (CNNs; RAT 2.0).

For these algorithms, the user is asked to manually annotate a small subset of the map. Regarding the template-based variant, the user has then to select a template for each type of place marker. From the templates, which are manually chosen by the user, the system creates automatically variations; based on the performance – measured with the annotated small subset of the map –, the best performing template variants are then chosen. In the template-matching algorithm, however, the normalized cross-correlation is used as a similarity measure because of its robustness against changes in brightness and contrast.

Regarding the detection trough a convolutional neural network, the manually annotated (small) subset of the map is used and split in a training and validation part. This is used to train the network, which has – at this stage – a very basic structure. It consists only of convolutional and pooling layers as presented in Figure 1.

Both the template matching approach and the convolutional neural network approach share similar performances. Our tests have shown – for the template matching approach – a detection precision of 98.2% and a recall rate (discovered place markers divided by all existing place markers on the map) of 87.7%. The convolutional neural network approach reaches only a precision of 94.4%, but gives a recall rate of 96.2%. So, there are more place markers found; but the result contains also some more wrong matches in between. Therefore, it depends on the use case, which result is "better", but for the manual post-correction it seems easier to check the CNN results for those additional wrong matches then finding the missed matches from the template-based approach.

The reason behind the use of the convolutional neural network approach has been an algorithmic limitation of the template matching approach. So far, RAT 2.0 uses only a fundamental convolutional system (at present, there are no additional techniques used, like, for example, data augmentation or pre-training).

As a future point, we work on training the convolutional neural network on multiple maps in order to find a classification model that learns the characteristics of place markers and that detects these on unseen maps.

Georeferencing of Place Markers in Digitized Early Maps by Using Similar Maps as Data Source

Winfried Höhn
winfried.hoehn@uni.lu
ILIAS Lab, University of Luxembourg, Luxembourg

Christoph Schommer
christoph.schommer@uni.lu
ILIAS Lab, University of Luxembourg, Luxembourg

Early maps are usually only accessible for a small group of researchers and librarians because they are precious and fragile. In the age of Digital Humanities, online access and search in digitized historical documents and early maps allows people from all over the world to work with such artefacts of cultural heritage. However, the digitization solely generates images of the artefacts without any access to the semantics of the documents. For most digital libraries of early maps (e.g. Old Maps Online) the available metadata include only information about the map, e.g. author, title, size, creation date, covered region. Unfortunately, there is only little information about the data contained in the map. Thus, even if data about place development or toponym changes is present in the maps it is not easily accessible. Since a single map can easily contain many thousands of place markers, proper tool support and automation of the annotation and georeferencing of each single place marker are of interest.

For modern maps or aerial photos it is possible to use GIS software to georectify the images by specifying a few control points, thus this problem is seen as solved. But early maps contain many sources of distortion, for example inaccuracies during surveying, combining data from different sources, focusing on creating a visually pleasing map instead of an accurate one. So there is in general no simple mapping between modern geocoordinates and an early map. Our existing Referencing and Annotation Tool (RAT) (Höhn et al., 2013) already simplifies the annotation and georeferencing of place markers. RAT supports the annotation and georeferencing by using template matching to identify place markers and by suggesting the most likely modern places based on an estimated mapping between the pixel-coordinates and geocoordinates of the already georeferenced place markers. To further refine the suggestions a phonetic search can be used, where the historic spelling can be used to restrict the results to similarly sounding place names.

Even with tool support like provided by RAT the georeferencing and annotation process starts from scratch for each map. Despite the automation there is still manual effort needed for place marker annotation. Since early maps have often been copied from each other or share some underlying survey data, there should be some regularity between maps that we can exploit. To take advantage of the possible similarities in early maps we present an algorithm to identify similar maps and create a link between the place markers of these maps. This results in georeferencing an early map in relation to another early map, which can be much simpler than georeferencing in respect to modern data. When the maps are based on the same data, they share some of their distortions and so the transformation between them gets simpler. They will also more likely contain a similar set of places. This reduces the problem of identifying a matching place compared to a modern database containing all known places, even the smallest ones which will not be shown in medium or small scale maps.

Before we can apply the algorithm to a pair of maps we need to identify suitable maps. These are maps that already have some georeferenced place markers and share at least four mappings to modern places. Also the place markers in these maps must be already recognized, but not necessarily georeferenced.

The algorithm for linking corresponding place markers of two maps *A* and *B* can be split in two steps:

1. Estimation of a transformation between the maps.The coordinate mappings in **M**, a bidirectional mapping containing the coordinates of the matching place markers in the two maps, are used to calculate the projective transformation between map *A* and map *B*.
2. Extending the linked place markers. Using the projective transformation calculated in step 1, map *B* is transformed into the coordinate system of map *A*. We will refer to the transformed map *B* as map *B'*. For each place marker in *A* the nearest place marker from *B'* is located. If for the place marker from *B'* also the place marker from A is the nearest, following checks are done:
   - The second nearest place markers have to be at least two times further away than the distance of the two place markers under consideration.
   - Both place markers must be connected to some place marker contained in **M** through edges in a Delaunay-Triangulation (Lee and Schachter, 1980) of map *A* and map *B*.

   If both previous conditions are true, add the place markers to **M'**.

   If **M'** has more elements than **M**, then set **M** to **M'** and continue with step 1.

M' is the resulting correspondence between the two maps. The steps of the algorithm are visualized in Fig. 3. The right column corresponds to step 1 and the left one to step 2. The rows show the different iterations of the algorithm. For all examples, the following maps are used: "*Nova Franconiae descriptio/Sculptum apud Abrahamum Goos. - Amsterdam: Joannes Janßonius, 1626*" referred to as Goos and "*Franckenlandt = Francia orientalis/Per Gerardum Mercatorem – o.O., ca. 1600*" referred to as Mercator.

These example maps both contain about 900 place markers and an overlapping area with about 800 place markers. For Goos, all place marker locations have been manually verified and for Mercator, the result of the template matching was kept. This resulted in an automatic detection of the correspondence of 755 place markers between the maps.

Another use case of this mapping is, that we can compare the automatically found place markers from two maps. We can highlight the differences between the sets of automatically detected place markers from two maps. This allows easily investigating the differences in the two sets of manually or automatically identified place markers. The identified differences highlight specific areas in these maps for further investigation. Two examples for detected differences between similar maps are shown in Fig. 1 and 2.

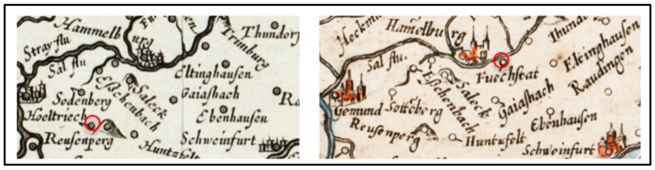

Figure 1. Corresponding map sections from Goos (left) and Mercator (right), where Goos has one place marker for Hoeltriech and Mercator one for Fuechstat which are both not in the other map.

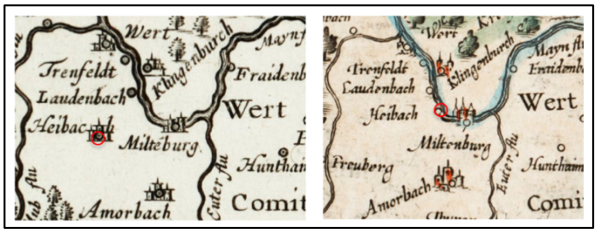

Figure 2. Corresponding map sections from Goos (left) and Mercator (right), where Heibach is in Mercator located at the river and in Goos far away from the river.

There can be various reasons for differences between two maps. First, there could have been an error in the detection of the place markers, which then helps to spot such problems. Second, it is a genuine difference between the two maps, which itself can have many reasons, e.g. different decisions which places should be included on a map or errors while placing the places on a map.

This work shows that it's possible to create a correspondence between place markers in different maps with not more effort than for georeferencing a map, which then only provides the region covered by the map. A similar map can be identified, if one exists in the database, and the place markers between the maps can be connected. This then allows reusing the georeferencing of single place markers from one map in the other map and identifying differences in the sets of place markers.

Future Work

This method can also be used to quickly identify similar maps and the differences in them. In this way it could be useful for researchers who want to find out which sources were used to create a map or who copied from whom. MapAnalyst (Jenny and Hurni, 2011) is an already existing tool for this purpose. If one map is considered as a possible copy of another map, MapAnalyst is a tool used by researchers to explore if this is true. The method proposed in this work would allow doing this kind of analysis on a larger scale while also highlighting the differences between the maps. Although this area was not our primary focus, we plan to evaluate the usefulness of our method on this task.

The information from linked place markers could help in further analysis of other metadata items, such as place type or place name. The linked place markers already make this information available from the other maps and it could for example be used to improve the OCR process of place names.

Appendix

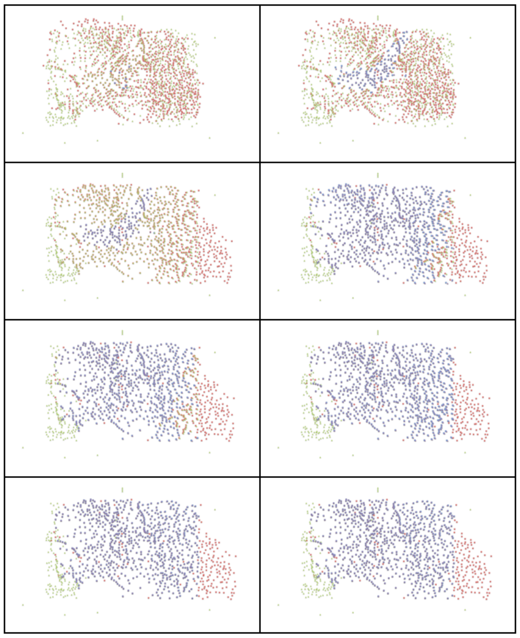

Figure 3: Visualization of the different steps in the matching procedure for Goos and Mercator, where the Mercator place markers are transformed into the Goos coordinate system. Triangles represent Goos place markers and squares Mercator ones. Green and red points don't have a mapping to a place marker in the other map, blue and purple ones have mappings. For further explanations see algorithm in main text.

Digital Access as an Equity Issue: The Community College and the Digital Divide

Polly Ruth Hoover
phoover@ccc.edu
Wright College, United States of America

In her nuanced discussion of teenagers and their use of digital technology, danah boyd argues that there are far-reaching consequences for assuming that young students are naturally digitally savvy and older adults are digitally hampered; we assume younger students are digital natives adept at using and understanding technology, while adults are digital immigrants, still learning the language and culture of the digital world (2014: 176-193). In fact, "Familiarity with the latest gadgets or services is often less important than possessing the critical knowledge to engage productively with networked situations, including the ability to control how personal information flows and how to look for and interpret accessible information" (boyd, 2014: 180), and she further cautions that "access to technology should not be conflated with use" (boyd, 2014:192).

But access is not universal. Even among teenagers, there are different levels of participation because of the access to the technology, the quality of the access related to the socioeconomic status of the teenager and the consequent different levels of digital skills (See Hargittai, 2008). While young, wealthier students may have access without sufficient knowledge about the limitations and challenges of their digital access, students from lower socioeconomic groups may not even have access except through the technology provided by their schools, libraries and other local institutions. The economic divide contributes to the digital divide.

This digital divide is further exacerbated by the institutional divisions and economic resources between two-year comprehensive community colleges and four-year institutions. Anne B. McGrail, a community college instructor herself, in her discussion of the role digital humanities might play in the community colleges, asks

"What are community colleges and their students missing out on in their exclusion from DH discourse, and how might intentional engagement with DH methods and tools help community college students become active agents of discovery and change in their lives?" (McGrail, 2016). These questions are particularly pointed given that many of the students at the comprehensive community colleges intend to transfer to four-year institutions and see the two-year colleges as an affordable first entry into college. If digital humanities is "the next big thing" as William Pannapacker announced in his 2010 blog in The Chronicle of Higher Education, is digital access another inequity in the system of higher education?

But how are digital access and inequality linked? At traditional four-year institutions, instructors may find the digital divide initially a challenge because of the access that students have had prior to their matriculation, but once they are enrolled, the institution provides digital access and support for both students and instructors. The learning curve may be steep for some students, but there are footholds on the way up. At the community colleges, however, which typically enrolls a variety of diverse students, a range from nontraditional students, who may be returning students apprehensive about their abilities, who may be limited in time and financial resources, and who are less likely to have access to or to use digital technology, to the more traditional students who nevertheless do not have the economic resources to access the newest digital resources, the digital divide begins at enrollment and may continue after enrollment. Both groups may be under-prepared, under-resourced and have issues of persistence. Yet, contrary to the four-year institutional model, the divide is further complicated because community colleges and their instructors, many of whom are adjuncts with peripatetic careers, are also under-resourced and lacking strong support for the digital humanities. The digital divide begins at enrollment and continues even after enrollment.

This presentation directly addresses these issues of digital access and equity among community college students. In particular, I examine the implications of the digital divide among the community college population: the problems of access and use among community college students both before and after they enroll, the different levels and aspects of digital preparedness for students, instructors and administrators, and the institutional issues of support and resources to create robust digital humanities at the comprehensive community college. I discuss in detail academic planning and creation of institutional support including establishment of Makerspaces and digital labs, professional development opportunities for faculty, and the creation of assignments that address some of these issues.

Measuring Canonicity: a Network Analysis Approach to Poetry Anthologies

Natalie M. Houston
natalie_houston@uml.edu
University of Massachusetts - Lowell
United States of America

Pierre Bourdieu has theorized culture as a field, a space constituted by the structural hierarchies and interactions among people and institutions. These relations encompass social and economic positions; competitive and cooperative intentions; as well as what he calls "position-takings"— all of the actions or decisions that produce a work of art and its cultural value. In order to understand the history of literature, Bourdieu argues that we must examine how its meaning and cultural significance gets produced within the cultural field: "the sociology of art and literature has to take as its object not only the material production but also the symbolic production of the work, i.e. the production of the value of the work" (Bourdieu, "Field" 37). Anthologies are a central mechanism in the symbolic production of artistic value as they present a selective literary canon as representative of a defined field of study.

Anthologies of literature thus both reflect and contribute to the structure of the cultural field, whether by reproducing its hierarchies of value or by contesting them. Anthologies frequently reprint some number of texts that have already been anthologized, along with new selections that may themselves over time become canonical. The changing selections presented in literary anthologies over time offer a microcosm of the field of cultural production as modeled by Bourdieu, a "force-field acting on all those who enter it . . . in a differential manner according to the position they occupy there" (Bourdieu, Rules 232). Each decision by an editor about which authors and texts to include in an anthology inevitably responds in some way to the decisions and values previously circulated in the cultural field. Anthologies are an important mechanism by which value gets assigned to particular texts in relation to one another: "Canonicity is not a property of the work itself but of its transmission, its relation to other works in a collocation of works" (Guillory 55). Thus to understand canonicity we must examine the relationships among literary works within the mode of their transmission, the anthology. In this paper I adapt methods of network analysis to examine the structure of the relationships among the poems included in 30 anthologies of Victorian literature published from 1880-2002.

Rationale

Literary canon formation and change has long been of concern to literary scholars. Writing in 1979, in terms that prefigure our current concerns with the scope of computational analysis, Alastair Fowler admits, “The literature we criticize and theorize about is never the whole. At most we talk about sizable subsets of the writers and works of the past. This limited field is the current literary canon” (97). Fowler defined six types of literary canons arising from various constraints and choices: official, personal, potential, accessible, selective, and critical. Anthologies are frequently taken to represent the literary canon because in themselves they constitute what Fowler calls a “selective canon,” a subset of works chosen by an editor (or editorial team) presumably for particular reasons. Anthologies make works accessible to a wide range of readers and also contribute to (or potentially constrain) the pedagogical canon, the subset of works that are taught (Harris 112-13). Anthologies often reflect the critical canon, as works that become interesting to scholars gradually start showing up in anthologies.

In the so-called “culture wars” of the 1980s-1990s, debates about multiculturalism and changes to the humanities curriculum frequently focused on anthologies and syllabi as synecdoches for university education (Graff). As John Guillory suggests, both the conservative and progressive sides in this debate tended to rely on “an ideology of tradition” which invokes “an autonomous history of literature, which is always a history of writers and not of writing” (Guillory 63). For Guillory and Bourdieu, the history of writing can only be understood in relation to mechanisms of cultural value.

When literary scholars write about anthologies, they frequently describe how the selective canon changes over time; examine the ideological assumptions that undergird the selection process; and point out historical or thematic gaps in anthology coverage. Yet the method that they use for doing this primarily rests upon counting authors (Golding, Harris, Latane). Others use the number of pages allotted to each author as a proxy for importance or weight within the anthology (Bode, Damrosch, Lecker).

Such approaches reify the ideology of tradition in assuming that author names alone adequately describe the complexities of literary history. As Guillory suggests, “histories of canon formation, when they consist primarily of a narrative of reputations, of the names which pass in and out of literary anthologies explain nothing. Such narrative histories fail to recognize generic or linguistic shifts which underlie the fortunes of individual authors by establishing what counts as literature at a given historical moment” (Guillory 64). By offering a network analysis approach that allows us to explore “what counts as literature” rather than just “who counted” in different anthologies, we can better understand the structures of value instantiated and reproduced in these collections and thereby better understand the history of taste and value. For example, rather than simply noting the unsurprising fact that the Victorian poet laureate Alfred Tennyson is included in all anthologies of Victorian literature and accepting that he is thereby a canonical figure, this approach allows for discovering more precisely which poems by Alfred Tennyson were valued in 1880, 1930, or 1980, and how those choices corresponded with selections from other poets.

Method

In this paper I explore the utility of several different approaches to analyzing the structures of canon formation as represented in poetry anthologies. These include:

- examining the structure of the bimodal network created between anthologies and poems;
- measuring anthology similarity based on textual couplings;
- examining the co-printing network created by connecting each poem in an anthology to every other poem printed in that same anthology
- Each of these approaches will be explored using the full dataset and by using chronological slices that will further the understanding of historical changes in the anthology canon.

In the first approach, I treat the relationships of poems to anthologies as a bimodal affiliate network. Although some researchers avoid bimodal representations of relationships because standard measures of centrality and other metrics do not apply, force-directed visualization of bimodal data “is often extremely effective for transmitting a holistic understanding of the whole dataset” (Borgatti 10). Faust and Borgatti have each recommended approaches to calculating centrality for affiliation networks that I will also explore. I also examine centralization (core-periphery structure) and structural equivalence measures for the affiliation network.

The remaining two approaches derive from established practices in bibliographic network analysis, particularly bibliographic coupling and co-citation analysis. Although co-citation analysis has largely overtaken bibliographic coupling in recent decades, recent comparative studies suggest that the utility of each approach varies depending on the timeframe and construction of the citation dataset (Boyack et al).

Bibliographic coupling draws an edge between two documents which each cite a third (Kessler). To understand the similarities among these anthologies, I create a textual coupling network, which consists only of anthology nodes, and create an edge between each anthology that prints the same poem. This network shows the degree of similarity between anthologies and filtering the poem nodes used to create the edge weights allows for exploration of which texts create distinctive differences among the anthologies.

In co-citation analysis, an edge is created between two documents which are cited together in a third document (Small). In my co-printing network, which consists only of poem nodes, I create an edge between poems that are printed in the same anthology. Calculating modularity for this network reveals clusters of poems that frequently occur together in the same anthology. These clusters are made up of texts by multiple authors and can be used to explore components of canonicity, such as thematic, formal, or aesthetic qualities shared by poems in each cluster.

This paper argues that network analysis is a useful approach to examine the structure of the cultural field of Victorian poetry as it was constituted in key literary and teaching anthologies published from 1880-2002.

From Mnemosyne to Terpsichore – the Bilderatlas after the Image

Leonardo Impett

École Polytechnique Fédérale de Lausanne, Switzerland

Sabine Susstrunk
sabine.susstrunk@epfl.ch
École Polytechnique Fédérale de Lausanne, Switzerland

Introduction

This study concerns Aby Warburg's last and most ambitious project: the Atlas Mnemosyne (or Bilderatlas), conceived in August 1926 and truncated three years later, unfinished, by Warburg's sudden death in October 1929. Mnemosyne consists of a series of large black panels, on which are attached a variable number of black-and-white photographs of paintings, sculptures, tarot cards, stamps, coins, and other types of images. The version we use is the one Warburg was working on at the time of his death, also known as the "1-79 version": it includes around a thousand images pinned on 63 panels (This version of the Atlas is published in various print editions, and available online). The Bilderatlas is a conceptual maze - the culmination of a life's scholarship in images and memory - through which perhaps the clearest thread is the concept of Pathosformel, or formula for (the expression of) passion. Much excellent work has been written on the concept but, to the best of our knowledge, nobody has yet tried to "operationalise" it - to turn it into a sequence of quantitative operations, or in other words, into an algorithm (Moretti, 2013).

The Pathosformel and its Operationalisation

On the most basic level, the Pathosformel describes the portrayal passionate emotions through a formula, a repeatable visual paradigm. The Pathosformel owes much of its force, as Salvatore Settis has pointed out, to its combination of semantic opposites: an "oxymoronic word, in that it merges in the same term the movement of pathos and the rigidity of the formula-schema" (Settis 1997).

Rather than attempting to operationalise the entire concept at once, we first break it down into its constituent components: first the morphology of formula, then the dynamism of pathos.

We turn to two well-studied cases of Warburgian formula: the Death of Orpheus (where Warburg first named the concept of Pathosformel), and the Nymph, headhuntress and Fortuna (Bilderatlas panels 46-48). Looking at Warburg's examples of the Orpheus-formula, reproduced in Figure 1, we can hardly stop ourselves from spotting a formula which repeats across the ages; but how could this intuitive similarity be measured?

Our algorithm comes as follows:

1. We isolate each individual body from its context. It is clear the Pathosformel relates to individual characters - the object of study thus becomes not panels or photographs in the Bilderatlas, but individual bodies.
2. We take only the skeletons of such bodies. Here we are eliminating colour, clothes, hands, faces, gender, age. This is not to say that such factors aren't important: but they are not elementary to the formula (see for example, André Jolles' letter to Warburg 23rd December 1900, where the formula of Ghirlandaio's Nymph hops between Judith, Salome, Tobias, Gabriel etc.– see Ghelardi, 2004; or the formula in Bilderatlas Panel 47 shared between Giambolo-gna's Samson and Donatello's Judith.)
3. We compare these skeletons by measuring the angles of the main limbs of the body, as described in Section 5.

Each of these steps is not merely a convenient quantification, but a conceptual wager. This is the strength of operationalisation as a critical tool: it forces one to be explicit about the conceptual choices one makes.

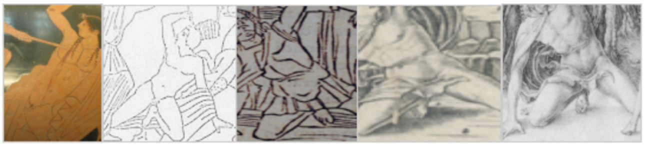

Fig 1: the Death of Orpheus: details from Warburg's example figures from classical antiquity to Dürer. Reproduced from Warburg 1905/1999

Anatomy, Emotion and Pose

Warburg was certainly influenced by Darwin's *The Expression of the Emotions in Man and Animals* (Darwin 1872) - which, when talking about human emotions, largely concentrates on the face. Indeed, the first figure of the book is an anatomical diagram of the face - "I shall often have to refer [...] to the muscles of the human face" (Darwin 1872 p.23). Warburg was certainly struck by the book - writing in his diary "ein Buch, das mir hilft!" (Gombrich, p.72). He was also interested and capable of studying the face in art (see e.g. his discussion of faces in Ghirlandaio's Confirmation in Santa Trinita, in The Art of Portraiture in the Florentine Bourgeoisie (in Warburg 1999 p.185), yet never in relation to Pathos - his descriptions of the Pathosformel relate exclusively to the *body*.

We can relate Warburg's decision to the large psychological literature on emotional recognition from bodies. Psychological studies are based on the Light Spots Model by Johansson (1973), often called 'biological motion', in which reducing body pose to 10-12 points - quite comparable to our own reduction - is judged to give a 'compelling impression of human walking, running, dancing etc.'. Using only Light Spots, observers can reliably tell gender and emotion from dynamic pose (Kozlowski 1977, Montepare 1987). Indeed, it has been suggested that our emotional understanding of faces is more influenced by our perception of the body than vice versa (Van den Stock 2007).

Encoding Pathos through Pose

The Atlas is, even by today's dataset standards, quite sizeable: 1000 images across 63 panels, containing an order of 10^3-10^4 depicted human figures. Scalable manual annotation is only therefore possible through crowdsourcing, which we did through the CrowdFlower platform.

Accurately annotating every visible figure in an image is a difficult and ambiguous tasks. Additionally, if different workers annotate different figures in the same image, the annotations cannot be collated or averaged. We therefore developed a two-stage annotation process:

Human figures are extracted from the painting by drawing bounding-boxes. This is done three times per image (by three separate workers).

Having aggregated the information from the first stage, separate images are produced for each human figure. Detailed pose information (the position of major body-points) is then added by three separate workers, with the information aggregated.

It should be clarified that the decision to annotate bodies in isolation (for annotation accuracy and just worker compensation) is quite separate to the earlier conceptual decision to analyse bodies individually, which relates to the object of study. It would be quite possible to do either one without the other.

Using this two-stage annotation process, we have presently annotated ⅓ of the Bilderatlas (by panels), resulting in 1,665 aggregated human poses. The collection and aggregation of the data are described in greater technical detail elsewhere (Impett, 2016).

Data Analysis: dimensionality reduction and dimensioned reductionism

Having encoded our static poses, how do we analyse and compare a collection of human figures of different sizes, proportions and orientations? We mirrored the poses horizontally and controlled for global rotation, ending up with a 11-dimensional vector *P*, describing the angles of the main limbs.

From this angular pose vector, we can use circular statistics to find a morphological distance $D_{a,b}$ between two poses P_a and P_b:

$$D_{a,\,b} = \sum_{i=1}^{10} |P_{a,\,i} - P_{b,\,i}|$$

Where $P_{a,\,i}$ is the ith angle of pose vector P_a , and $||_\alpha$ is the angular radian distance:

$$|x|_{\alpha} = min(x, \pi - x)$$

These morphological pose-differences are perceptually meaningful over short distances. On a larger scale, they become less perceptually significant: is a sitting person 'closer' to a lying or standing person?

In order to make our distance analysis perceptually relevant, therefore, we first clustered our 1,665 poses into 16 clusters by rotational K-means clustering (Dordet-Berdanet and Wicker 2008). Our two-stage clustering system is therefore as follows:

I. K-means clustering (to produce meaningful clusters)

II. Hierarchical clustering (for within-cluster morphological information)

The number of clusters K is chosen by looking at the inter-cluster variance over K. The result of the first stage of clustering is shown in Figure 2; Figure 3 shows an example section from a hierarchical map of Cluster 1.

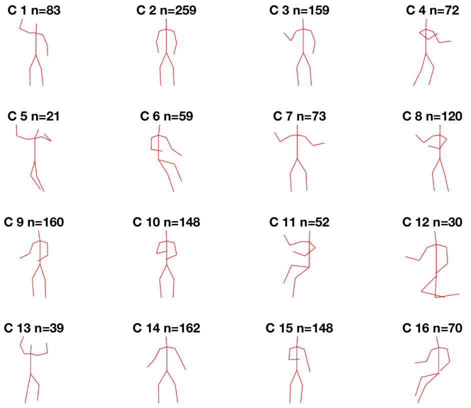

Fig 2: our 16 pose-clusters

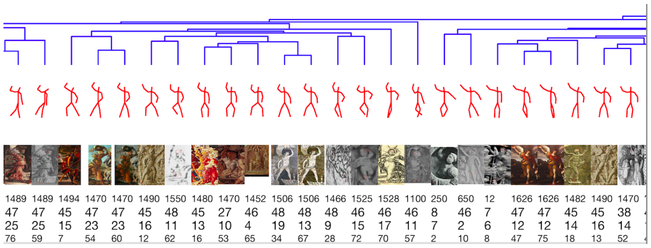

Fig 3: a detail from a dendrogram of different poses within the Bilderatlas, produced by second-stage clustering within Cluster 2

Unity of the Pathosformeln: from distant to close reading

Some of the clusters clearly represent physical activities - sitting, praying, embracing, dancing - whilst others seem more subtly communicative or expressive in nature. Having reorganised the 1,665 figures into 16 mean-centred clusters, we proceeded to trace the classical Pathosformeln - identified in the Atlas by primary and secondary literature - through our clusters.

The canonical Pathosformeln are mainly mythological figures (Perseus, Pentheus, Orpheus) or recurring allegories (Graces, Nymphs, Fortuna). They were previously described as distinct, and we expected to find a taxonomy of such formulae through our clustering analysis.

On the contrary, the statistical result was much stronger: a complete morphological unity. Almost every identified Pathosformel falls into Cluster 1, with few false positives - over 80% of the figures in Cluster 1 are an identified Pathosformel. The handful of exceptions are all borderline cases, placed in peripheral to Cluster 1 (Clusters 7 and 13).

Looking more closely at the images themselves, as in Figure 4, this becomes visually clear: not only do the Pathosformeln share certain pose features (most importantly, a raised arm) present nowhere else in the dataset. To date, however, the authors know of no art-historical literature that has identified such morphological unity.

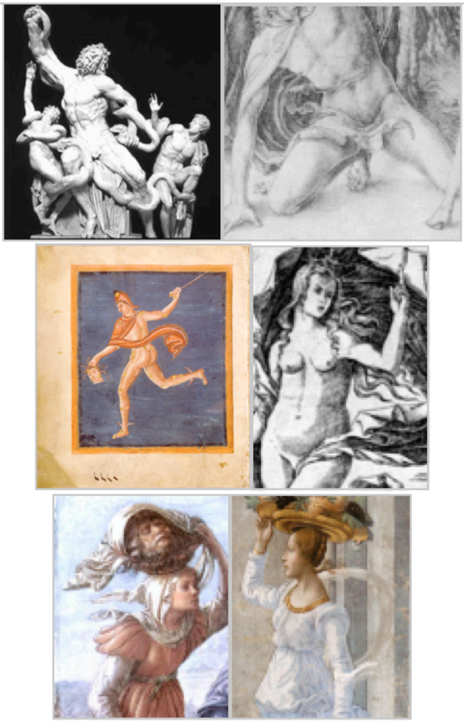

Figure 4, clockwise from top-left: Laocoön, Orpheus, Fortuna, Nymph, Judith, Perseus - all except Orpheus are in the Atlas. The identified Pathosformeln share distinguishing features from the other characters in the Atlas: a raised arm, most often accompanied by a lowered second arm, and a slight twist of the body.

Concluding remarks

Our morphological model for Pathosformel is statistically strong: but what are the art-historical implications? The oppositional symmetry and raised arm of Cluster 1 (Fig. 2) reminds us of a Contrapposto, but the bodies themselves are far removed from such classical balance (e.g. Fig. 4, top). Rather than movement, tension (between upper and lower body) seems to be the fundamental element of Pathosformel - the nature of which will be the subject of a subsequent publication.

Our morphological analysis has shown that static pose can identify Pathosformeln, and that a study of static pose through a large collection of artistic works can identify links across styles, periods and cultures.

Automatic detection of pose is a focus of the current research, and will allow us to expand our art-historical models beyond the Bilderatlas. Humans (thus bodies, and poses) are unsurprisingly the most common feature of human art, and therefore make excellent objects of study for an art history of the Longue Durée (Robb 2015).

Introduction

The Academy of Sciences and Literature in Mainz provides online access to the Regesta Imperii - a very extensive historical dataset based on documentary sources of German-Roman kings. About 125,000 regestae of emperors and popes are searchable and viewable in this online portal. The current user interface offers direct access to single documents through different form-based search facilities, as well as through a catalogue that directly reflects the structure of the regestae volumes as they have been created in this long-term project. In order to further improve access to this large data volume, we suggest an additional approach based on coordinated views. The usage of coordinated view approaches is very common in many domains (Stasko et al, 2008, Vuillemot et al, 2009, Koch et al, 2011). However, there is no publicly system available, which would provide a suitable access to this historical dataset. The motivation for this new approach is twofold. On the one hand, we improve the support for search and exploration tasks in this historical data set that are based on imprecise information needs or on a less deep understanding of the available information. In practice, such imprecise queries can quickly lead to an overwhelmingly large number of search results. Allowing users to create and refine queries in a visual way, while offering immediate feedback on the number of entries requested, can help to cope with underspecified queries and help refining them iteratively (Jänicke et al, 2012). On the other hand, we offer a powerful means for visually analyzing the available information and understanding complex relationships by providing different linked perspectives on subsets of the collections. These perspectives include views on historic persons and entities as well as temporal and spatial information contained in the regestae. A usage scenario shows successful application of the approach.

Visual approach

We implemented a web-based visualization that is easily available to humanities scholars, since it does not require users to install software. The web-based visualization uses the library Data-Driven Documents (D3) (Bostock et al, 2011) and runs with a web browser supporting HTML5, SVG, CSS, and JavaScript.

Data processing

In the Regesta Imperii database all documentary sources of German-Roman kings are available in full text (xml-files). This data set consists of regestae volumes and register information. Regestae volumes are short summaries of a text and contain important metadata of a document, such as the title of the document, an ID for the unique assignment, date of issue, and place of issue as name and coordinates.

Since places, persons, and institutions may be known by different names, entries can be overlooked within the full-text search. Therefore, place and personal registers provide a central resource for work with the regestae and contain a list of places, persons, institutions, and additional information, such as the numbers of the regestae in which the entity is mentioned, a reference to another entity entry (if available), and a unique id.

Since the regestae have been manually digitized, the xml-files can contain syntax or other transmission errors,such as different date formats, geo-coordinates or tags. Therefore, the data must be parsed and well prepared in order to use them for a visual analysis.

Visual approach

After the regestae and register volumes have been successfully parsed and loaded into our system, users can start their exploration in the main view as depicted in Figure 1. The main view consists of the five coordinated views: (A) timeline view, (B) map view, (C) register view, (D) overview filter view, and (E) results view.

Figure 1. The interactive visualization approach for exploring and analyzing regestae of royal and papal records.

We initially depict all available data and enable users to create and refine queries in a visual way iteratively, to reduce the overall set. For example, users can select certain time periods and places in which the regestae were published or persons and places that are mentioned in the regestae.

The timeline view consists of two stacked timelines and enables users to select a time period by clicking and dragging, as depicted in Figure 6, comparable to the Simile approach (Huynh, 2008). The first timeline allows a coarse filtering and represents the whole-time range of the regestae. Once a timespan is selected, the second timeline is updated and permits a finer selection of the upper selected time range.

To get an overview where the regestae were published, users can discover the map view as depicted in Figure 2. The map view uses the JavaScript library Leaflet (Agafonkin, 2014) which supports interactive features such as zooming and panning. The red circles in the map represent places where the regestae were published and the circles size is scaled proportionally to the places occurrences, similar to the approach (DARIAH-DE, 2015). This helps to get a quick overview of important places. When hovering over a circle, a tooltip shows the corresponding place name. By selecting one or more circles (highlighted in yellow), the places are added to the search query.

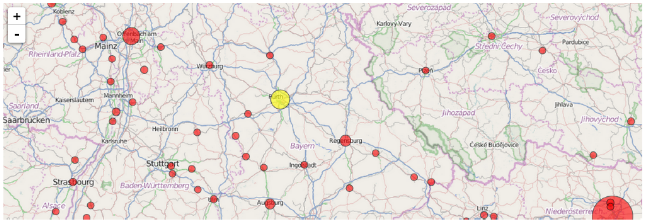

Figure 2. The map view gives an overview where the regestae were published.

The register view represents the entities from the register volumes in an alphabetically sorted hierarchical structure as depicted in Figure 3. Users can explore the different entries by clicking on the different hierarchies. Nodes, which contain further entities are displayed in darker color. Furthermore, users can select one or more entities to adapt the search query.

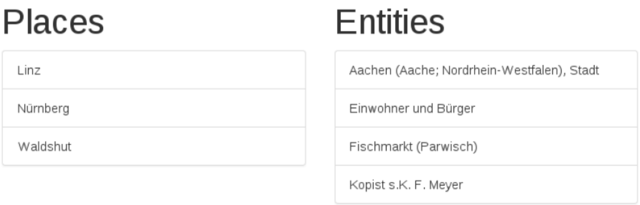
Figure 3. The register view represents all persons, places, and institutions which are mentioned in the regestae.

From the overview filter view, users can get a summary about all the selected places and entities which determine the search results. In addition, users can deselect places and entities from the list to adapt the search query.



Places	Entities
Linz	Aachen (Aache; Nordrhein-Westfalen), Stadt
Nürnberg	Einwohner und Bürger
Waldshut	Fischmarkt (Parwisch)
	Kopist s.K. F. Meyer

Figure 4. The overview filter view gives an overview of all selected places and entities.

Based on the combined search query, the result view lists all regestae entries, which are included in the search results as depicted in Figure 5. For each entry, the list displays the following metadata: title of the regesta, issuer, place and date of issue. By clicking on the icon in the column entities, users get the information of all entities occurring in the regesta in a separate list view. Furthermore, users can select the icon in the last column uri to jump directly to the corresponding regesta entry on the web page of the Regesta Imperii. This enables users to analyze the regesta in detail.

Figure 5. The result view displays all regestae entries which are included in the result set.

Usage scenario

In the following section, we present a usage scenario that occurred during one of the joint workshops of users from the Academy of Sciences and Literature in Mainz and the developers of the approach. Therefore, our usage scenario represents instead the insights and lessons learned through several sessions with two experts from the Regesta Imperii.

In a first step, the expert explores and analyze the map view. That way, she gets a quick overview of the places where regestae were published. During the exploration, the place Nürnberg (Nuremberg) has aroused her interest, since she has already examined these entries a long time ago. To find out more about the regestae entries, she starts a search query by selecting Nürnberg (Figure 6A) in the map view and discovers the search results in result view. However, the result set is too large for a further deeper analysis. Therefore, she refines the search query by selecting the time period from 1440 to 1450 in the timeline view (Figure 6B), because she is especially interested in the early regestae entries. As the next step, she searches for entities that are mentioned in the regestae with the aid of the results view. She finds out that there are many connections to French entities. To further analyze that, she selects the hierarchy “Frankreich, Königreich” (France, Kingdom) in the register view, as depicted in Figure 6C. By adjusting the search query, she received a specified subset of the collection for a further analysis. This way, she finds that primarily French kings are mentioned in the regestae entries.

During the analysis, she learns from the map view that Neustadt near Bremen (Figure 6D) has many regestae entries which she did not expect. To inspect this in detail, she selects Neustadt and explores the result list. By analyzing the different entries in the list and web page of the Regesta Imperii, she finds out that the geo-coordinates were manually digitized incorrectly. Consequently, the expert corrects the entries in the database by assigning these entries to the actual place Neustadt near Vienna.

While these sessions, we received a lot of feedback that showed that our approach improves access to the large data volumes of the Regesta Imperii and facilitates search and exploration tasks, as well as assisting in understanding complex relationships and gaining new insights.

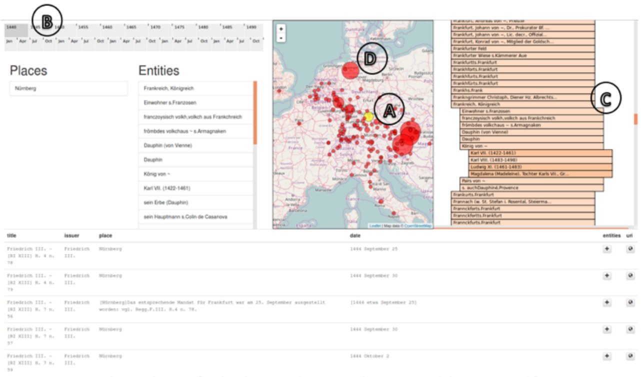

Figure 6. An example search query for the place Nürnberg, French entities, and the time period from 1400 to 1440.

Conclusion and future work

The presented interactive web-based approach has been evaluated through expert feedback that recommends it as an effective method for exploration analysis.

We are planning to extend the different linked views to support users with additional information. Concerning this issue, we have implemented the relative distribution of the regestae volumes in the timeline view, as depicted in Figure 6, and we are currently working on the co-highlighting between the views. We will also ensure that experts from the Regesta Imperii are able to correct errors that arise during the digitization process interactively.

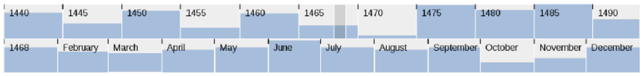

Figure 7. Timeline filter view of the selected year 1468 with a relative distribution of the regestae over time.

How can digital methods be used to conceptualize historical research projects, including their teams, approaches, methods, and outputs? What methodologies can be used to synthesize and analyze archival records, workshop plans, photographic evidence, and oral histories? This co-authored paper describes an ongoing effort by a collaborative group* to understand and recover the work of Father Roberto Busa, commonly thought to be the "founding father" of Digital Humanities. Starting in 1949, Roberto Busa, S.J., began a landmark collaboration with IBM to build a lemmatized concordance to the works of St. Thomas Aquinas. In 1956 Busa founded the world's first humanities computing center in Gallarate, Italy, located after 1961 in a former textile factory stocked with rows of IBM punched-card machines. This was CAAL, the *Centro per L'Automazione dell'Analisi Letteraria*—the Center for the Automation of Literary Analysis. There Busa and his mostly female student operators processed the monumental *Index Thomisticus*, a selection of the Dead Sea Scrolls, and other texts, from 1961-1967 (Terras and Nyhan, 2016; Jones 2016). However, there is much that is still unknown about Busa's research approach and methods. We aim to recover what Busa and his operators did. By repurposing punched-card office machinery for *literary* data processing, Busa created an important pre-computing technology platform for humanities research, one which has become obscured over time. We aim to reverse engineer and reconstruct not just a particular technology (punched-card machines) but that first humanities computing center as a whole. By doing so, we will explore methods that can be useful for other historians as they look back upon site-specific projects and groups, using digital tools and methods to effectively interleave and investigate historical data sources.

Jeffrey Schnapp of Harvard's metaLAB has remarked that "every cultural object is a network" (Schnapp, 2015). Reverse engineering involves taking apart a device or system not to replicate it but in order to better understand its design and purpose, its networked relations. The goal in this case is to break down and experimentally reconstruct the networked cultural objects--including specific machines, architecture, infrastructure, and human operators--that amount to the components of that Italian humanities computing center, and in that way to model a more capacious idea of "digitization" itself. We make use of a cluster of convergent practices:

1. The digitization of archives--paper-based documents with Dublin Core derived metadata, but

also 3D digitizations of physical artifacts such as punched cards, relay switches, etc.

2. A cultural-heritage virtual model of the architectural space, a 3D immersive environments of the center itself, created through basic photogrammetry and using Maya + the Unity engine, based on multiple archival images, as well as new scans of the building, still standing outside Milan (though much altered).
3. Emulations of forgotten or obsolete technologies, punched-card data processing systems as well as other "adjacent" technologies in the 1950s and 1960s.
4. Oral histories and audio-files of interviews with surviving punched-card operators, Busa's secretaries, and others

The overall objective is to model this important early research center and its activities through a series of purpose-driven and interlinked emulations, 3D spaces, oral histories, and digitized documents and artifacts. We employ metadata to map archival materials and emulations onto the models in order to understand the material history of what is usually taken to be the first humanities computing center. In the process, we complicate the key terms themselves, including *first* and *computing*.)

Most of what has been known to date about Busa's early literary data processing was derived from a handful of his own publications– first by Winter (1999); later, Jones (2016) drew on the Busa Archive to contextualize and extend his narrative account. Rockwell and Sinclair (2014) and Terras and Nyhan (2016), have continued to clarify the story in different ways. Actually modeling the machinery and workflow allows us to address specific questions about this important moment in the birth of linguistic data processing and humanities computing, such as:

- What were the precise roles played by human operators *between* the automated stages, sorting card decks, lemmatizing word lists, programming machines via plugboards, etc.? (How were these roles stratified and gendered?)
- What source texts were used for input and how were they prepared and marked up so that the operators could use them as the basis for what they punched on the cards?
- At what stage did IBM agree to print customized punched cards with what amounted to data fields unique to Busa's projects? What was the nature of the data ontology behind these customizations?
- What is the evidence that the work of Busa's center contributed to larger technology developments at IBM, such as Peter Luhn's development of the influential KWIC (keyword in context) protocol for information retrieval?

Additional questions will surely arise during the ongoing process of modeling and cross-checking archival materials and oral histories.

Although Busa's humanities computing center is our focus, we believe this methodological approach would be useful in other instances, as a way to conceive of digitization as a process of modeling artifacts and documents in relation to technology and infrastructure. We draw on theoretical approaches and methods associated with media archaeology (Parikka, 2012; Emerson, 2014; Rockwell and Sinclair, 2014; Sinclair, 2016), creative historical prototyping (U Victoria Maker Lab; Sayers et al, 2016), the archaeology of science (Haigh, 2016; Schiffer, 2001), and on the methods and expertise of digital archaeology in the field of cultural heritage, including its attention to issues of access and preservation (Koller, 2009; London Charter, 2009).

The presentation at DH 2017 will include slides containing selections from the 800 historical photographs of Busa's center, as well as other images, audio files, and demonstrations, including a prototype 3D virtual model of the center. The paper will explain the project's practical aims and theoretical significance: for example, we address current debates in digital humanities about the influence of text-based analysis on today's definitions and practices; or debates about possible alternative genealogies for DH (Klein, 2012). It will also spotlight the role of gendered labor in early humanities computing, and the entanglements of early humanities technology research with corporate and government funding. Our broader methodological purpose is to take up in practice what Jeffrey Schnapp has called the "defining design challenge of our epoch"—"to weave together information and space in a meaningful fashion" (Schnapp, 2015), and the methods will be of interest and use to others who are approaching multimodal archives and interpolating the information therein.

Personality and Politics: Myers–Briggs Personality Types on Twitter in the US 2016 Presidential Election

Patrick Juola
juola@mathcs.duq.edu
Duquesne University, United States of America

Sean Vinsick
sean.vinsick@gmail.com
Duquesne University, United States of America

As a social media platform, Twitter (twitter.com) offers opportunities to examine public reactions in what could be described as the world's largest village square. Twitter provides an opportunity not only to participate in public discourse, but even to shape it. However, to fully understand this discourse, it is helpful to understand the people behind the discourse. Stylometric authorship profiling (Argamon, et al, 2009) provides an example of this. People are free to post their opinions, but by analyzing the writing style of the individual tweets, we can infer other attributes of the individual authors.

In this study, we infer personality categories using the well-known Myers-Briggs Type Inventory (MBTI) to analyze whether or not there are any differences between the supporters (and detractors) of the major party candidates, Hillary Clinton (D) and Donald Trump (R). The MBTI categorizes people along four major axes, as encoded in a four-character summary (for example, ENFJ: Extroverted, iNtuitive, Feeling, Judging). We have shown (Gray and Juola, 2011; Juola et al., 2013) that personality can be inferred with high accuracy from writing, and further that MBTI personality types can be gleaned specifically from Twitter feeds. Using The EthosIO system developed by Juola & Associates, we have applied this (Juola, Vinsick, and Ryan, 2016) to large-scale analyses of the demographics of personality on Twitter, finding substantial differences between the accepted distribution of personality in the general US population and between the distribution of personality among active Twitter participants. For example, introverts make up approximately 50% of the general US population, but nearly 80% of active Twitter users. Similarly, nearly 3/5 of the general US population are "sensing" (S) [as opposed to "intuitive" (N)], but half or fewer Twitter users are. Two specific subgroups, INFP and INFJ, are vastly overrepresented on Twitter, being only about 5% of the overall US population, but 30% or more of the samples gleaned from Twitter.

We extend this to analyzing personality differences between politically disparate groups of Twitter participants. As with (Juola, Vinsick, and Ryan, 2016), we harvested a large group of user names from the Twitter sample feed, selecting users whose public tweets included one of several political hashtags. Based on the hashtags seen, we divided participants into four groups: anti-Clinton (identified by one or more of '#NeverHillary', '#CrookedHillary', '#WhichHillary', '#DraftOurDaughters', '#hillary4prison', '#hillary4prison2016', '#StopHillary', '#CrimeWithHer', or '#Killary'); pro-Clinton ('#ImWithHer', '#Clinton', '#ClintonKaine16', '#ClintonKaine2016', '#HillaryClinton'], '#ClintonKaine', '#WhyIWantHillary', '#HillarysArmy', or '#Hillary2016'); anti-Trump ('#NeverTrump', '#dumptrump', '#trumptaxreturns', '#dontvotefortrump', '#dumpthetrump', '#boycotttrump', '#trumpsexism'); and pro-Trump ('#ImWithYou', '#TrumpTrain', '#MakeAmericaGreatAgain', '#TrumpPence16', '#TrumpPence2016', '#Trump', '#AltRight', '#VoteTrump', '#TeamTrump') This gave us approximately 600 user names for each of the four groups in our preliminary dataset. These user names were submitted to the EthosIO personality analyzer to produce distributional data for each subgroups.

We therefore had in our preliminary corpus 651 pro-Clinton subjects, 587 pro-Trump subjects, 635 anti-Clinton subjects and 639 anti-Trump subjects, for a total of 2512 total user names, divided across 16 MBTI categories (details in full paper). As expected from previous work, the overall statistics do not match US demographics; for example, types ISFP and INFP are strongly overrepresented in all samples, as are introverts in general. Our interest, however, is in whether or not political differences also show up as personality differences as well. In plainer language, does the average Clinton supporter have a different personality than the average Trump supporter?

We tested this hypothesis with a variety of chi-squared tests (df=15 throughout). At the most basic level, we found extremely significant differences (p ~ 10^-9) between Clinton supporters and Trump supporters. We also found significant differences (p ~ 10^-12) between "Democrats" (either pro-Clinton or anti-Trump) and "Republicans" (pro-Trump and anti-Clinton). Examining cells in detail suggest that ISFJ and ISFP are both overrepresented among Democrats while ESTJs and INFJs are overrepresented among Republicans.

By contrast, there was no significant difference (p > 0.10) between "Anti" and "Pro" subjects, despite the possible participation, for example, of third party supporters who are opposed to both Trump and Clinton. Similarly, we found no significant difference between pro-Trump and anti-Clinton subjects, or between anti-Trump and pro-Clinton subjects, suggesting that other factors than personality are affecting whether a person chooses to self-express in favor of a particular candidate or in opposition to that candidate's rival(s).

In this study, there are a number of potential confounding factors, the effects of which have not yet been assessed. The first is simply the presence of active attempts to manipulate the dialogue, for example, through the use of automated 'bots' (Kollanyi, Howard, and Wolley, 2016), or simply through the use of "sock puppets," multiple identities in an attempt to create a an appearance of consensus and of larger margins. A second factor is the issue of overlapping categories. Approximately 20% of our preliminary "anti-Trump" sample also self-identified as "pro-Clinton," and similarly, approximately 20% of the anti-Clinton sample self-identified as pro-Trump. More counterintuitively, approximately 5% of the anti-Clinton sample also identified as anti-Trump, and approximately 5% of the pro-Clinton sample was also pro-Trump. This may be due to a third confounding factor, the inability of simple keyword spotting to identify the use of irony (for example, in posting a link to an article highly critical of Trump's campaign and using the '#Trump' hashtag to draw attention to it). As we continue this analysis, based in part on data to be collected during the final and most intense week of the campaign, we will address these issues (and discuss our methods of address in the final paper).

We have therefore shown, using text analysis of Twitter on a moderately large scale, that there are significant differences between the types of people who self-identify as supporters (and opponents) of one of the major candidates in the 2016 US presidential election. We have also shown that there does not appear to be significant personality-related differences between whether one supports one's chosen candidate or opposes the other one. We have also confirmed the previous results (Juola, Vinsick, and Ryan, 2016) about the general distribution of personality types on Twitter, and hasten to point out that the differences we have identified are still relatively minor and that the overall distribution of personality types in both camps are broadly similar to the distribution of personality types on Twitter in general. However, our results show, first, that, in keeping with prior work, inferring personality type via Twitter is practical and useful. Second, they show that personality may play a factor in the selection of one's chosen candidate.

Finally, the question of "who are Trump's voters?" against "who are Clinton's voters?" will no doubt interest historians for decades. Our results provide some insight into possible psychological motivations in addition to the more traditional social, political, and economics reasons, and may therefore enrich future discussion and scholarship.

Nota bene

This version of the paper was written approximately one week before the actual 2016 election and will be updated as appropriate.

Network analysis of the manuscript context of Old Icelandic literature

Katarzyna Anna Kapitan
kak@hum.ku.dk
University of Copenhagen, Denmark

Aim

This paper explores the possibilities of applying computer-assisted methods to the field of Nordic manuscript studies, with a special emphasis on a network analysis—in a broad sense—of manuscript context. A case study of one Icelandic legendary saga's manuscript tradition is used to test the hypothesis that the manuscript context can carry information about ethnic genre associations of the text (on ethnic genre in Old Norse literature see: Harris, 1975; on legendary sagas as a genre see: Quinn, 2006).

Research Questions

Hrómundar saga Gripssonar traditionally belongs in the corpus of legendary sagas (fornaldarsögur); it was included in the second volume of Rafn's (1829) *Fornaldarsögur Norðrlanda*, and in Björner's (1737) *Nordiska kämpa dater.* The saga as it is known today, however, is a post-medieval re-working of a metrical version of the story known as rímur (Brown, 1946), and is probably not much older than seventeenth century. Therefore it does not necessarily fit well with the other texts included the corpus of legendary sagas, as they usually date from the fourteenth and fifteenth centuries (Driscoll, 2005:207). This makes *Hrómundar saga Gripssonar* an interesting case study for investigations of the text's genre affiliation in the extant manuscripts preserving the saga. Does it appear frequently in manuscripts with the older legendary sagas or with younger rímur-based narratives? To answer this question, I first examine the manuscript context of legendary sagas as a corpus, based on collaborative research with Rowbotham and Wills (Kapitan et al., 2017); second, I examine the position of *Hrómundar saga Gripssonar* within the corpus and its relationships with other texts.

State of the Art

Much discussion in the field of Old Norse studies centers on whether the legendary sagas deserve to be considered a separate literary genre, or should instead be analyzed as chivalric literature (Quinn, 2006). One of the main reasons for these considerations seems to be the fact that the term fornaldarsögur is not attested in the medieval texts; it was introduced in the early nineteenth century by C.C. Rafn, who published a collection of texts under the title *Fornaldarsögur Norðrlanda* (Rafn, 1829). Rafn's selection of texts and the definition of fornaldarsögur as a corpus of texts dealing with events taking place in Scandinavia before the settlement of Iceland, however, was not detached from pervious scholarship of early eighteenth century (Lavender, 2015). The current discussion on the legendary sagas as a corpus (or a genre) is polarized around contradicting opinions. Some scholars suggest that the legendary sagas had to be considered a separate category in pre-modern period, because they are frequently bound together in the manuscripts (Guðmundsdóttir, 2001:cxlvii; Mitchell, 1991:21) while others, using the same argument, emphasize strong connections between the legendary sagas and the chivalric sagas (Driscoll, 2005:193). Additional problems arise when classifying the generic hybrids (Rowe 1993; 2004) appearing within the corpus, or distinguishing between the legendary sagas (fornaldarsögur) and the late legendary sagas (fornaldarsögur síðari tíma; Driscoll 2005). Even though scholars eagerly turn towards the manuscript context to support their claims regarding the genre classification, no comprehensive overview of the legendary sagas' codicological context has yet been presented. This gave rise to the project *Stories for all times* conducted at the University of Copenhagen, which created a complete catalogue of manuscripts preserving legendary sagas. The catalogue contains 818 TEI-conformant XML-based manuscript descriptions with over 8000 items, 1764 of which are classified as legendary sagas and 920 as chivalric sagas. This amount of data is much too large to be analyzed manually, therefore it is necessary to apply computer-assisted analysis in order to draw some general conclusions regarding this corpus and the relationships between these texts.

Methods

The first part of my paper, which aims to establish the position of *Hrómundar saga Gripssonar* within the wider context of the manuscript, draws on the network analysis of the corpus, conducted in collaboration with Rowbotham and Wills (Kapitan et al., 2017). There, the codicological context of a text was considered as a system of relationships between texts, and following Hall's (2013) approach in his network of chivalric sagas, texts were represented as nodes, manuscripts as edges, both visualized with the free visualization software Gephi. The second part is based on database queries aimed at obtaining detailed information about particular manuscripts and their contents. The main focus of the analysis was to examine the manuscripts preserving the complete texts of *Hrómundar saga Gripssonar* in Icelandic, therefore the manuscripts containing excerpts and translations were ignored. The distribution of texts appearing frequently alongside *Hrómundar saga Gripssonar* by century has been obtained using XPath queries of the online catalogue *Stories for all times*.

Main Findings

As a result of this research, the hypothesis can be confirmed: generally, texts belonging to one genre appear most frequently in manuscripts with other texts belonging to the same genre. However, an interesting transmission history of *Hrómundar saga Gripssonar* suggests a close association of this saga with the late legendary sagas, and in particular *Bragða-Ölvis saga.* Both *Bragða-Ölvis saga* and *Hrómundar saga Gripssonar* are post-medieval re-workings of older metric versions of the stories (rímur), and for both texts the manuscript AM 601 b 4to (Árni Magnússon Institute, Reykjavík) was suggested as the witness carrying the best text of the saga (Andrews, 1911; Brown, 1946; Hooper, 1934; Hooper, 1932). Even though *Hrómundar saga Gripssonar* appears most frequently with texts classified as late legendary sagas in pre-1800 manuscripts, after 1800 the texts classified as (traditional) fornaldarsögur start to dominate. The late *Bragða-Ölvis saga* dominates the pre-1800 setting, but the distribution changes in the nineteenth century when *Þorsteins saga Víkingssonar*, *Starkaðar saga gamla*, *Friðþjófs saga ins frækna*, and *Hálfs saga Hálfsreka* appear more frequently (as presented on figure below). *Starkaðar saga gamla* is a late-eighteenth century saga written by Snorri Björnson (1710-1803), utilizing traditional legendary motifs of Saxo's *Gesta Danorum* and legendary sagas (Driscoll, 2009:209; Simek and Hermann Pálsson, 1987:331), so its co-occurrence with other legendary sagas starting from the eighteenth century onwards is not surprising. The three remaining texts that started to appear more frequently alongside *Hrómundar saga Gripssonar* in nineteenth-century manuscripts were all published in the same volume of Rafn's *Fornaldarsögur Norðrlanda*, in which *Hrómundar saga Gripssonar* was published (volume II); likewise Friðþjófs saga ins frækna, and *Hálfs saga Hálfsreka* appeared in Björner's edition from 1737 together with *Hrómundar saga Gripssonar.* This shows how printed editions influenced the saga's transmission in the manuscript form. A text, which once showed strong connections to another rímur-based narrative, became detached from its previous setting and gained new, print-influenced context after becoming part of printed editions.

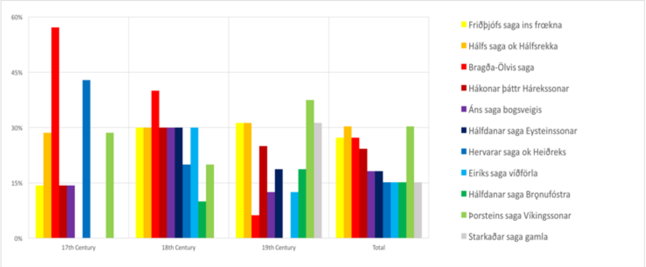

Figure 1. Texts appearing frequently with Hrómundar saga Gripssonar in manuscripts by century

Relevance

The topic of this paper fits in the advertised panel "Quantitative stylistics and philology, including big data and text mining studies," as it employs database quarrying and network analysis of significant amount of data.

Acknowledgements

The author of this paper owes a great debt to Tarrin Wills for merging the data from various databases (fasnl.ku.dk, skaldic.abdn.ac.uk, handrit.is, onpweb.nfi.sc.ku.dk) to obtain the input data for the network analysis, and to Tim Rowbotham, who worked on standardizing the uniform titles and genre classifications in the XML-files in the Stories for all times catalogue.

Transforming Theater History through Crowdsourced Transcription

Lindsay King
lindsay.king@yale.edu
Yale University, United States of America

Peter Leonard
peter.leonard@yale.edu
Yale University, United States of America

Based on the pilot Ensemble project from NYPL Labs, Ensemble @ Yale is an experiment that aims to transform the archives of Yale’s theater history through crowdsourced transcription. Going beyond OCR of digitized text, Ensemble @ Yale uses human expertise to extract semantic relationships and structured data from digitized programs, enabling future digital scholarship on a rich cultural collection.

The Yale School of Drama is internationally recognized as a leading theater training program, and its associated professional company Yale Repertory Theatre has premiered numerous plays that have gone on to successful productions in New York and elsewhere. The long list of renowned alumni attests to substantial research interest in records of their careers at Yale. Yale University Library's archives of productions on campus, dating back to the School of Drama's origins as a department in 1925, are housed in several disparate special collections units. The vast majority of these records exist solely in print. Even searchable digital finding aids often require that researchers have knowledge of the time period when a particular person was at Yale and might have been in a show. Neither personal names nor show titles are available as entry points in minimally-processed collections like the Yale Repertory Theatre and Yale School of Drama Ephemera Collection, the archive this initial experiment seeks to investigate.

Ensemble asks its users to choose important parts of digitized performance programs, transcribe the text, identify important relationships or characteristics, and verify the work of other users to make the collected data more robust. Crowdsourced transcription relies on individual judgment to pull out features of interest to scholars. A key challenge in crowdsourcing is enabling users to produce the most comprehensive metadata possible, while not making data entry feel like a chore. We strove for a feeling of progress and accomplishment when users complete short tasks, hoping to replicate NYPL Labs' success at attracting transcribers.

Designing the user experience for Ensemble requires a different kind of organization than the original collection/box/folder order, so that the relationship of the crowdsourcing workflows to the special collections materials is both clear and engaging to users. Many transcription systems present the user with random pages one after another. In this case, however, we sought to avail ourselves of a highly-motivated user base with specific domain expertise. For these potential users, navigating directly to programs from specific years they knew well would be a more satisfying experience and also allow the project to leverage their knowledge.

As our work to digitize the programs within one of the archival collections commenced, NYPL Labs shifted focus toward creating a more general crowdsourcing tool. Recognizing the broad applicability of the ideas behind crowdsourced transcription, NYPL Labs partnered with Zooniverse, a "citizen science" organization with a history of crowdsourcing scientific archives, to produce a generalized, reusable toolkit. The resulting software project, called Scribe, was produced with the support of a National Endowment for the Humanities Digital Humanities Implementation Phase grant. With this abstracted transcription engine as a springboard, we began to adapt Scribe to work with multipage theatrical objects in a new version of Ensemble.

Among other adjustments, we are adding a name-authority component to the verification workflow, to enable better searching of names and roles in the database. For production staff roles, a researcher might want to know that a term like "scenery" was used at a specific time, but "set design" and "settings" at other times. They may also want to be able to search for the names of everyone who worked on that enterprise in a certain organization or geographic location. Verification and normalization will be done by librarians "offstage," allowing retention of users' direct transcriptions as data. The resulting structured data will have multiple research applications, from simple database queries for answering reference questions to network analysis and other data visualizations.

In this paper, we will present the project's progress after the public launch of Ensemble @ Yale this spring. Beyond its usefulness for creating structured data from print archives, we are also interested in Ensemble's potential as an outreach tool to engage scholars, alumni, and the general public with archival materials in the library's collections. As an experiment, Ensemble was envisioned as a model that could be expanded to additional repositories at Yale. Beyond that, the proof of concept may inspire similar projects at other institutions that could expand into linked collections of theatrical data across multiple repositories.

Overcoming Data Sparsity for Relation Detection in German Novels

Introduction

Within the context of social network analysis (SNA) for literary texts the automatic detection of family relations and similar social relations between characters in novels would be an important step for any macroscopic analysis. Manual labeling is rather inefficient since the text snippets that explicitly describe a relation are sparse within the long text documents; therefore we combine two techniques, active learning and distant supervision, which are often used to overcome data sparsity.

Inspired by distant supervision which uses a high quality information resource to support information extraction from other data, we used expert summaries of literary texts, German novels mainly from the 19th century, since relevant text snippets are much more frequent in summaries. Then we applied an uncertainty-based active learning strategy labeling selected sentences from the novels and the complete summaries. The results show that training on summaries and evaluating on data derived from novels yields reasonable results with high precision and low recall similar to humans solving this task.

After a brief discussion of related work in the next section, the data set and the necessary preprocessing for this work are explained in section three. Section four describes our method in detail and shows strengths and weaknesses.

Related work

The challenge of training an algorithm capable of generalizing from a small set of manually labeled data has created a multitude of approaches like active learning and distant supervision. A good survey on active learning is given in (Finn et al., 2003). Usually it starts with a seed set of manually annotated data. A classifier is then trained and new instances that appear to be very different from the current training data are proposed for manual labeling until the quality of the classifier stops improving. Successful algorithms include Multi-instance Multi-label Relation Extraction (Surdeanu et al., 2012).

Another method specifically used for relation detection in newspapers is distant supervision (Mintz et al., 2009): Given some facts (e.g. Michelle Obama is the wife of Barack Obama), usually stored in a database, the aim is to match those facts to the text (e.g. every sentence containing Michelle and Barack Obama indicates that they are married). The training of the classifier is then performed on the pseudo gold data. Even though the idea appears to be simplistic, the results are comparable to those obtained by active learning.

Jing et al. (Jing et al. 2007) successfully applied relation extraction for SNA in an end-to-end manner and reported that most problems were caused by coreference resolution.

Data and preprocessing

We created three datasets from 213 expert summaries, available from Kindler Literary Lexicon Online, and 1700 novels derived from project Gutenberg and annotated relations between characters:

- We split 500 novels into sentences and applied an uncertainty-based active learning strategy (explained below) to iteratively select new examples (in this case full sentences) using a MaxEnt classifier. In total, about 1100 sentences were labeled in this way. This was labeled by annotator 1. (From now on, we refer to this as the novel data set)
- We split our summaries into sentences and applied the same active learning strategy to select new examples, thereby generating about 1300 labeled sentences. They were labeled by annotator 1. (From now on, this is called summaries I)
- Each of the 213 summaries has been manually labeled with all character references, the co-reference chains amongst them and relation annotations for pairs of entities that are explicitly mentioned to be in a relation. They have been labeled by annotator 2. (From now on, we call this summaries II)

The applied active learning strategy started by manually selecting about 20 seed training sentences which were manually labeled with information about relations between character references. The seed examples were chosen by matching a wordlist containing indicative expressions (such as “mother”, “father”, “servant” or “loves”) to the text, to enable the classifier to learn relations from different relation types in an unbiased fashion (which usually changes during training because the underlying distribution of relations is heavily biased towards family relations). On those seed examples we trained a binary Maximum Entropy classifier which was applied to thousands of unlabeled sentences. The sentences were then ranked by uncertainty of the classifier. Uncertainty for a sentence, in our case, was defined by extracting all pairs of character references first, applying the classifier to every pair and then assigning the minimum probability to the sentence. The classifier was retrained on command of the user and the ranking of the unlabeled sentences restarted. By applying this strategy, we observed that the average certainty of a sentence rises with every iteration and decided to stop the manual labeling once there was no sentence with a classifier probability below 60% for the novels and 70% for the summaries (this does not mean we reached saturation in classification gain).

For the labeling, we used a total of 57 hierarchically ordered relation labels, inspired by (Massey et al., 2015) (see figure 1). All these labels relate person-entities with each other, such as “motherOf” or “loves”.

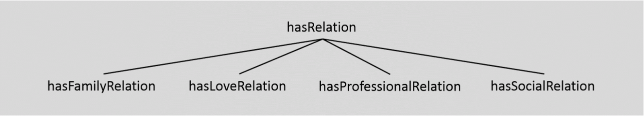

Figure 1: The four main relation types which are further differentiated in 57 relation types in total

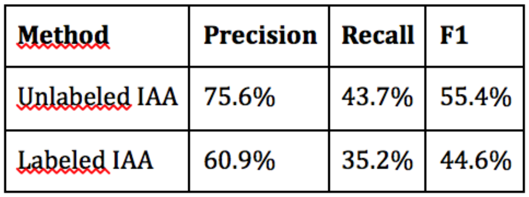
The inter-annotator-agreement (IAA) between summary data set I and summary data set II was measured in two ways:

1. A true positive appears when both annotators mark the correct span of the annotation as well as the correct label and the correct arc direction where a correct arc links the two entities in the direction as it is expressed in the text (labeled inter-annotator agreement).
2. A true positive appears when both annotators mark the correct span and arc direction of the relation (unlabeled inter-annotator agreement).

Table 1 gives an overview of the IAA results.



Method	**Precision**	**Recall**	**F1**
Unlabeled IAA	75.6%	43.7%	55.4%
Labeled IAA	60.9%	35.2%	44.6%

Table 1: IAA results, the comparison assumed summaries II as gold and compared summaries I to it.

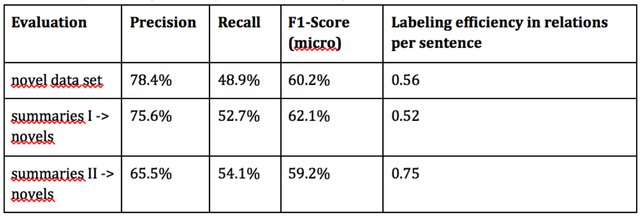
Additionally, we determined 55.5% as the normalized Cohen's Kappa between our annotators. The results for the IAA are surprisingly low (amount of labeled relations in summaries I compared to the relations in summaries II). The reasons are yet unclear and have to be investigated; we assume that one of them is the high variance of possibilities to express social relations. Labeling the complete summaries may also be more difficult because the annotator needs to read the text completely and might use background knowledge to annotate relations which are only implicit in the text.

Method and evaluation

To compare the transfer from summaries to novels, we trained a classifier, specifically a maximum entropy classifier based on boolean features generated from rule templates because previous work has shown that this classifier is superior in classification accuracy compared to kernel machines, pure rule based approaches or other supervised classifiers such as support vector machines (Krug et al., 2017). Training was done on a data set using the annotations as features and the classifier was applied either to test data from the same set or to a different data set resulting in three evaluations:

- A 5-fold cross evaluation within the novel data set.
- Training on the snippets of the summaries (summaries I or summaries II) and evaluation on the novel data set.

Table 2 shows the result of this experiment for the in-data and cross data evaluation of the relation detection component.



Evaluation	**Precision**	**Recall**	**F1-Score (micro)**	**Labeling efficiency in relations per sentence**
novel data set	78.4%	48.9%	60.2%	0.56
summaries I -> novels	75.6%	52.7%	62.1%	0.52
summaries II -> novels	65.5%	54.1%	59.2%	0.75

Table 2: The results of a 5-fold in-data set evaluation for both of the data sets and the results for a cross-data set evaluation. Each number represents a micro-average score, i.e. we count every true-positive, false-positive and false-negative in a document and calculate the average scores based on these quantities. We choose the micro score since the label set is rather unbalanced between classes. The efficiency of an approach is measured by calculating number of relations / number of sentences.

Results that are very similar to working directly on the novel (60.2% F1) are achieved by using the model trained on the extracted sentences from the summaries to retrieve information about character relations in the novels (62.1% resp. 59.2%). Since our test data is generated by active learning and only the most difficult examples were chosen for labeling, we expect our results to be a lower bound compared to data in complete novels.

If we use a model trained on the complete summaries, we experience a drop in precision. This drop was to be expected, since the amount of additional labeled relations in the novels is high according to the IAA results (this manifests in the low recall in table 1) as well as can be seen in the labeling efficiency. Altogether, the quality and efficiency of using a classifier trained on summaries are comparable to training on the novels directly based on our data.

Summary

We presented an approach to increase labeling efficiency for relation detection in German novels by transferring knowledge from summaries to novels. It could be shown that using the summaries as trainings data will achieve similar results to using the novels, but the summaries are much shorter and relevant sentences are much more frequent. The inter-annotator agreement for this task is also relatively low which may point to an explanation for the comparatively low results of the automatic approach.

La production de l’espace dans l’imprimé d’Ancien Régime: le cas de la Gazette

François Dominic Laramée
fdl@francoisdominiclaramee.com
Université de Montréal, Canada

Quelle image mentale du monde un Français de l’époque moderne pouvait-il se tracer au contact des journaux et des livres? Comment caractériser le « message géographique » transmis par les ouvrages savants, les périodiques, les descriptions et les récits de voyage du XVIII^{e} siècle — et peut-être discerner leur influence sur les événements historiques ?

L’étude d’une telle problématique, qui constitue le cadre de ma thèse de doctorat, implique de faire appel à un corpus vaste et diversifié qui doit être examiné à la fois à l’aide de méthodes numériques de traitement de la langue naturelle et par une lecture intensive de documents ciblés. Mais comment appliquer la lexicométrie, la fouille de textes et l’apprentissage machine à des textes en français du XVIII^{e} siècle, pour lesquels il n’existe pas de modèle de langage approprié dans les logiciels d’analyse courants ? Et comment adapter des algorithmes conçus pour des sources numériques récentes et de très bonne qualité à des documents endommagés par les siècles, parfois océrisés à partir de microfilms alignés de façon imprécise, ou même handicapés dès leur création par une typographie irrégulière qui mystifie les outils d’océrisation ?

Cadre théorique

Depuis les années 1980, le tournant géographique inspiré par les travaux du philosophe Henri Lefebvre (Lefebvre, 2000) a démontré que l’espace est une construction sociale. Pour les Français du XVIIIe siècle, cette construction passait le plus souvent par la lecture, seule source de connaissance couramment disponible au sujet d’espaces lointains. Comment peut-on utiliser les concepts d’espace et de lieu (Tuan, 2006), de co-présence et de mobilité (Lévy, 1999; Lussault, 2007) pour reconstruire l’imaginaire spatial suscité au sein de communautés de lecteurs par l’accès simultané aux mêmes textes (Anderson, 2006), en particulier ceux des journaux et périodiques?

Corpus et méthodologie

Cette présentation examinera les résultats obtenus lors d’une analyse d’un corpus tiré de la Gazette (renommée Gazette de France en 1762), principal périodique de nouvelles sous l’Ancien Régime (Feyel, 2000). Une version numérisée de la Gazette est disponible sur Gallica, l’archive en ligne de la Bibliothèque nationale de France ; l’état de conservation des documents imprimés à partir desquels cette version a été constituée est cependant inégal, et par conséquent le taux de succès estimé à l’océrisation varie entre 99 % et 76 % ou même moins. Les fichiers .txt issus de l’océrisation ne peuvent donc pas être employés tels quels : non seulement les formes (chaînes de caractères représentant des mots) sont-elles fréquemment endommagées, mais des informations aussi importantes que les limites séparant deux articles et les lieux d’origine de ceux-ci sont également sujettes à un taux d’erreurs inacceptable. La retranscription manuelle du corpus, formé de dizaines de milliers de page en PDF, aurait quant à elle entraîné un coût d’acquisition déraisonnable. Quant aux méthodes usuelles de correction automatique des erreurs d’océrisation (Lopresti, 2009), elles se sont révélées peu efficaces dans ce contexte, ne permettant de réduire le taux d’erreur effectif que de moins de 0,1% — et le plus souvent dans des segments du corpus sans lien direct avec les questions de recherche étudiées.

Pour traiter ce corpus, il a donc fallu faire appel à une méthode itérative, où le choix de questions de recherche auxquelles répondre a déterminé les éléments du corpus qu’il fallait reconstruire et où les résultats de l’examen d’une version transitoire du corpus a guidé le choix des questions de recherche pour l’étape suivante. Cette méthode repose sur l’identification dans le corpus, à l’aide de l’algorithme de Levenshtein (Crump, 2014), de formes potentiellement produites par une reconnaissance incorrecte d’un certain nombre de mots-clés choisis en fonction d’une question de recherche; sur l’inspection visuelle de ces formes candidates pour éliminer de la liste celles qui correspondent manifestement à d’autres mots de la langue française que les mots-clés recherchés; et sur l’extraction semi-automatisée de métadonnées pertinentes compte tenu de la question de recherche étudiée, à partir du texte océrisé et d’une inspection visuelle du document PDF d’origine. En pratique, le taux de faux positifs obtenus en détectant toutes les formes dont la distance de Levenshtein par rapport aux mots-clés est de 3 ou moins dépasse les 95%, mais la sélection visuelle des candidates véritablement prometteuses permet d'augmenter le nombre d'occurrences utilisables pour une analyse ultérieure de 25% à 30%, et ainsi d'assurer une meilleure couverture des éléments pertinents du corpus que ce qui aurait été possible autrement. (Notons que ces occurrences récupérées incluent non seulement les résultats d'erreurs d'océrisation mais aussi des orthographes inusitées des mots-clés recherchés.)

La présentation tracera les grandes lignes de ce processus, des résultats obtenus avec la Gazette, des éléments de la méthode qui se sont montrés généralisables à d'autres corpus bruités, et des limites que la prudence impose à la fois aux questions de recherche auxquelles il convient d'appliquer une telle méthode et aux conclusions que l'on peut en tirer. Afin d'augmenter le niveau de confiance envers les résultats, une multiplicité de méthodes numériques ont été appliquées aux textes et aux métadonnées, l'utilisation d'un seul algorithme, toujours problématique (Schmidt, 2013) étant particulièrement suspecte dans un contexte où la fiabilité des données laisse à désirer. Ces multiples méthodes incluent le partitionnement (Chen et al., 2004), la cartographie numérique, divers décomptes et l'étude des cooccurrences lexicales — soigneusement contrôlée par une inspection visuelle afin d'éliminer les effets de bord causés par l'absence d'un modèle de langage approprié pour le français du XVIIIe siècle — avec le logiciel de textométrie TXM (Heiden et al., 2010). Seuls les résultats à la fois cohérents entre les différentes méthodes et trop flagrants pour être expliqués par un accident de répartition du bruit dans les textes d'origine ont été conservés pour communication.

Résultats

Les premiers résultats portent sur la représentation de l'Amérique et du monde colonial au cours de la période entre 1740 et la fin de la Guerre de Sept ans. Il a notamment été possible de démontrer que l'immense majorité des articles de presse mentionnant les colonies provenaient de Londres ou de la péninsule ibérique plutôt que de la France elle-même et qu'ils présentaient le phénomène colonial d'un point de vue étranger ; que les colonies britanniques et le Brésil occupaient une place beaucoup plus importante que les colonies françaises dans l'imaginaire spatial construit par la Gazette ; et que la sous-représentation du monde colonial français dans les textes, et en particulier celle de la Nouvelle France continentale, était exacerbée en temps de paix, où le Canada devenait pratiquement invisible. À la lecture de ces résultats, il est permis de se demander si, du point de vue d'un lecteur de la Gazette, le moment colonial français en Amérique n'aurait pas semblé chose du passé, bien avant la signature du traité de Paris qui a consacré la cession du Canada à la Couronne britannique. Des recherches sur la co-présence de différents toponymes au sein des mêmes articles, des thèmes associés à ces toponymes et à la distance imaginaire représentée par les fréquences de mentions de lieux dans la Gazette sont en cours et leurs résultats pourront être intégrés à la présentation.

Toward Reproducibility in DH Experiments: A Case Study in Search of Edgar Allan Poe's First Published Work

Mark D. LeBlanc
mleblanc@wheatoncollege.edu
Wheaton College, United States of America

Summary

Reproducing experimental results is a hallmark of empirical investigation and serves both to verify and inspire. This paper is a call for more systematic documentation of computational stylistic experiments. Publishing only summaries of the methods and results of empirical work is an artifact of traditional print media. To facilitate experimental

reproducibility and to help the growing community who wish to learn how to apply computational methods and subsequently teach the next generation of scholars, the publication of results must include (i) access to the digitized texts, (ii) a clear workflow and most essentially (iii) the source code that led to each and all of the experimental results. By way of example, we present the steps and process in a GitHub repository for computationally probing the unknown and contested authorship of an 1831 short story entitled "A Dream" as we seek evidence if this work is similar to other attributed works by Edgar Allan Poe. The entire framework is intended as a pedagogical jumpstart for others, especially those new to computational stylometry. If Poe did write the story, it would be his first published work.

Introduction

As the Digital Humanities gains access to a wide array of digitized corpora and matures to a discipline that creatively defines new methods for computationally close and distant readings, a growing gap has emerged between those who apply sophisticated programming, e.g., Stylo In R (Eder *et al.*, 2016) and those who are new to the game and need an introduction to the field. Typical of the community spirit in DH, significant efforts are underway to bridge this gap, including web-based tools for entry-level exploration including Voyant Tools (Sinclair and Rockwell, 2016) and Lexos (Kleinman *et al.*, 2016) and domain-specific introductions to programming, including Jockers' text (2014) and the Programming Historian (Crymble *et al.*, 2016). This paper attempts to narrow the gap by encouraging both sides to document their experimental methods more fully to embrace previous calls for the replication of experimental methods (Rudman, 2012 *et al.*) and thereby teach effective practices by "leaving a trail" of experimental methods that enable others to execute and extend.

A Good Mystery: Towards Reproducibility

A GitHub repository or "repo" offers a workflow that explores whether an 1831 story published under the attribution of only 'P' might have been written by Edgar Allan Poe. If so, it would be Poe's first published work. In addition to sharing a set of analytical methods applied in this experiment, the broader methodological-pedagogical goals are two-fold: (i) the dissemination of data and code should be championed as a cornerstone of DH research, thereby facilitating the replication of results and (ii) to share a workflow so that others may apply similar analyses to their texts of interest.

The workflow is stored as a set of numbered folders containing the texts *and* scripts (code) needed to complete each step. The workflow includes: collecting texts, the preprocessing, tokenization, and culling decisions made, unsupervised cluster analyses (k-means, hierarchical-agglomerative, bootstrap consensus tree), and supervised classification methods using Stylo in R's Delta, SVM, and NSC models. Each step represents scaffolding for a "teachable moment" with materials provided so faculty can more easily use them with students.

Scrubbing, Tokenization, Cutting, and Culling

Lexos, a web-based, open-source workflow of tools (Kleinman, *et al.*, 2016) was used to upload texts and "scrub" them by applying the following options: (i) convert words to lowercase, (ii) all punctuation was removed, (iii) however, a single word-internal hyphen and word-internal apostrophes were kept, and (iv) all digits were removed. Each individual word is considered as its own token. Larger stories were segmented ("cut") into pieces. We experimented with various culling options, e.g., keeping only the most frequent words that appear in each text at least once.

Cluster Analysis

As a set of initial probes, we compared the contested story "A Dream" to (i) other stories attributed to Poe and (ii) mixed in with stories by other contemporaries. In the repo, we share four variations using cluster analysis:

1. K-means clustering on only Poe's stories (using Lexos)
2. Hierarchical agglomerative clustering on only Poe's stories (uses a Python sklearn module and a script to convert the cluster to ETE and Newick formats)
3. K-means clustering when all stories by each author are concatenated together (Lexos)
4. Bootstrap Consensus Tree (using Stylo in R).

The result from the Bootstrap Consensus Tree is shown in Figure 1. Of interest is that each author's stories cluster consistently together (with the exception that Bird's initial section of "Sheppard Lee" and his "Calavar" are found in different clades, at six and eight o'clock). "A Dream" clusters with the smaller Poe texts. As you'll see, we couldn't resist tossing in the four stories sometimes attributed to Edgar's brother Henry ("Monte Video", "A Fragment", "The Pirate", and "Recollections"). These four stories are found within the cluster of Poe's known works (*c.f.* Collins, 2013).

A series of cluster analyses often serves well as a preliminary exploration, especially for scholars who are new to this game. Some of the file sizes are very small (*e.g.*, one-half of the Poe stories in this corpus have fewer than 2000 words) and when strict culling is enforced (top-N words that appear at least once in each segment), the available set of words is reduced to only 38 when dealing with "A Dream" and the other eighteen Poe stories. That noted, these exploratory investigations shed some light on why some scholars consider that Poe's "first published tale may have been 'A Dream'" (Silverman, 1991, p87).

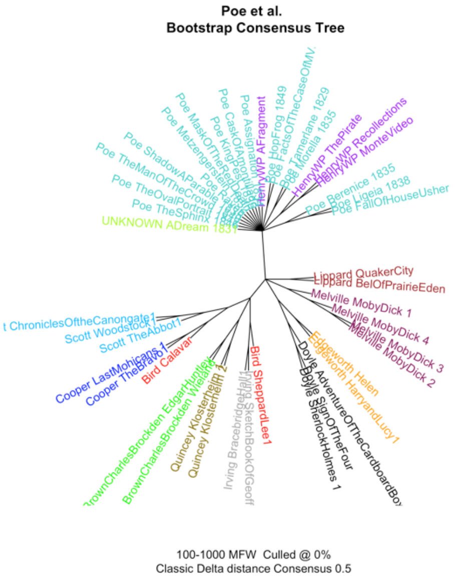

Figure 1. Using Stylo in R Bootstrap Consensus Tree (BCT) showing "A Dream" consistently clustering with other Poe stories. The BCT aggregates results over multiple cluster analyses and shows those texts that satisfy a consensus number of the individual trials. Using 12 different authors and at least two texts by each author for a total of 46 stories, Stylo formed clusters of the texts for the following frequency bands when using the most-frequent words: 100 to 1000 MFW.

Classification

Three classification models differentiated authorial writing style as implemented in Stylo in R. We scripted in R alongside Stylo to test "A Dream" over N-trials (N=10, 100) using a random selection of files for training sets in each trial. At least one text from each author is also included in the test set for each trial. A follow-up Python script parses the collected results to build confusion matrices for each author to provide metrics on how well the models predict each author's works. The most-frequently occurring, top-40 words (MFW, 1-grams) that appear in all the texts at least once were used.

		Confusion Matrix values for all Poe Stories			
Model	Attributions of "A Dream" to Poe	True+	True-	False+	False-
Delta	9	13	200	0	7
NSC	10	16	170	30	4
SVM	7	14	198	2	6

Table 1: Attributions of the contested story "A Dream" over ten (10) trials with "A Dream" and another randomly selected Poe story in the test set in every trial. Confusion matrix values for results of testing Poe texts over all trials provide overall measures of model effectiveness. In the three cases where "A Dream" was attributed to a different author, Poe was ranked second.

Summary

We offer a start to an exploration to collect evidence as to whether Poe may have written the 1831 story "A Dream" (*c.f.,* Schöberlein (2016) who used the most frequent character 3-grams and attributed the story to Poe using Delta, but not so when using NSC nor SVM models). Evidence and methods aside, a GitHub repo provides a framework to share experimental workflows in a spirit similar to Jupyter notebooks, as well as one that facilitates both reproducible results and opportunities for subsequent contributions.

Notes

Forming an appropriate corpus is hard: thanks to Sam Coale, Ryan Cordell, Cary Gouldin, David Hoover, Shirrel Rhoades, and Ted Underwood. Four undergraduates: Weiqi Feng, Alec Horwitz, Jingxian Liu, and Khaled Sharafaddin worked with us on this problem. Thanks to Maciej Eder for his help with Stylo in R.

Ecriture et visualisations numériques

Christophe Leblay
christophe.leblay@utu.fi
Université de Turku, Finland

Gilles Caporossi
gilles.caporossi@hec.ca
HEC Montréal, Canada

Depuis les années 80, plusieurs méthodes pour analyser le processus d'écriture ont été utilisées (Miller & Sullivan, 2006). L'outil principal pour analyser le processus d'écriture est le fichier d'enregistrement, appelé *log*, qui contient de façon exhaustive et détaillée l'ensemble des opérations effectuées par le scripteur lors de la rédaction d'un texte (Sullivan & Lindgren, 2014). Les données qui y sont emmagasinées sont considérables, et lorsqu'elles ne sont pas préalablement traitées, elles sont hostiles à l'analyse humaine (Caporossi & Leblay, 2014). Ce traitement préalable nous semble donc déterminant dans l'accès aux données scripturales enregistrées. Autrement dit, il est impossible d'exploiter les programmes d'enregistrement de l'écriture (dits aussi de *temps réel*), sans procéder, au préalable, à un *redéploiement visuel* des données obtenues. Les structures sous-jacentes des données ainsi représentées sont généralement plus propices à l'analyse que les données brutes inexploitables. Plusieurs étapes sont alors nécessaires avant même de pouvoir utiliser les techniques d'analyse à proprement parler. Le processus simplifié par lequel les données sont acquises, traitées et analysées se résume ainsi : a) *enregistrement*, b) *partage*, c) *tri*, d) *recherche*, e) *représentation visuelle des données* et f) *analyse* (Manyika*, et al*., 2011). Plusieurs de ces actions ont déjà été étudiées de manière individuelle et ont été l'objet de création de logiciels visant à enregistrer le processus d'écriture et à le représenter dans l'une ou l'autre de ses dimensions (Caporossi & Leblay, 2011). Ces logiciels sont tous différents et généralement destinés à un projet de recherche particulier (Sullivan & Lindgren, 2014). Certains sont conçus pour traiter l'information et la retransmettent ensuite à l'utilisateur de façon simplifiée, sous la forme d'une représentation visuelle. L'utilisation de représentations graphiques de données, appelées de façon plus générale *visualisations*, consiste à explorer et essayer de comprendre les grands ensembles de données (Yau, 2011) Elles permettent notamment d'identifier des tendances, structures, irrégularités et relations entre les données sur une certaine période temporelle (Minelli, et al., 2013, p. 110). Le format compact de la visualisation agrège les données et utilise les capacités cognitives de l'humain (Blanchard, 2005) Le but principal de l'utilisation de ces images représentant le processus scriptural est de laisser l'œil trouver des structures sous-jacentes parmi les données (Tory & Moller ,2004).

Il existe deux grands modèles de représentations qui prétraitent les données de manière à pouvoir appliquer des techniques d'analyse linguistique de données. Le tout premier, attaché aux travaux réalisés par une linguistique cognitive, est celui qui a été développé dans le cadre des *Systèmes d'Information Géographique*, ou SIG ; ont utilisé ce mode de représentation principalement les études suivantes : *LS Graph* (Lindgren & Sullivan, 2002 ; Leijten, *et a*l., 2006), *Genèse du texte* (Doquet-Lacoste, 2003), *GIS Graph* (Lindgren, *et al*., 2007), *Timeline* (Wengelin, 2009) et *Inputlog* (Leijten, *et al*., 2013). Le second, celui que nous proposons, en réaction au premier, a été développé en associant, de manière interdisciplinaire, la linguistique génétique et la théorie mathématique des graphes.

La représentation par les graphes (des nœuds reliés entre eux par des liens, ou arcs) permet de mettre davantage en relief l'aspect dynamique de l'écriture (cf. figure 1). Celle-ci est orientée sur la chronologie du processus d'écriture (Leblay, 2011). Un nœud (nommée *cellule* dans notre travail) représente la production d'une suite ininterrompue de frappes au clavier (caractères et espaces).

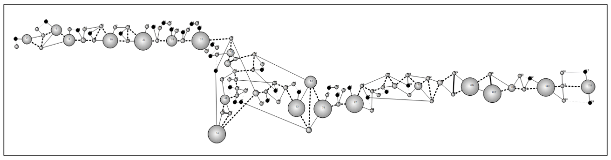

Figure 1. Visualisation globale par graphe : l'écriture experte (nuance de gris : en sombre = une suppression ; en clair = un ajout)

Ainsi, si l'écriture consistait en une suite ininterrompue de frappes de caractères d'un début jusqu'à une fin, un texte serait visuellement représenté par une seule et unique *cellule* dont la taille dépendrait uniquement du nombre de caractères et d'espaces produits. Or, il existe des retours et des pauses dans ce qui est déjà écrit. Les retours dans le texte sont ainsi marqués: la cellule se divise dès l'instant que la continuité topographique est rompue, bien qu'un lien perdure pour matérialiser le lien temporel (couleurs/nuance de gris et épaisseur du trait). Deux cellules se lient donc quand un lien topographique est créé, le tout au gré des écritures et réécritures.

L'une des particularités de ce travail de visualisation est de bien gérer la transformation et les mouvements du texte grâce aux nœuds représentant des parties de texte (ajoutés, supprimés) reliés ensemble par des liens (ou arcs) définissant leur relation, soit chronologique ou spatiale(Southavilay, Yacef, Reimann, & Calvo, 2013) est possible de voir le contenu de ces nœuds. Telle que mentionnée par Caporossi et Leblay (2011), cette représentation en couleurs, ou en nuances de gris, montre l'aspect temporel de la rédaction, soit le moment exact où le scripteur a effectué chacune des opérations représentées, en lien avec celles qui la précédent comme avec celles qui la suivent. Les possibilités d'analyse de ces structures ont déjà été étudiées dans le contexte du processus de l'écriture (Leblay & Caporossi, 2014 ; Caporossi & Leblay, 2015).

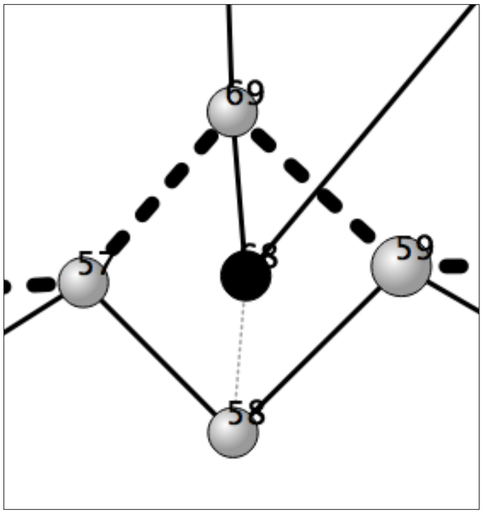

Figure 2. Sous-graphe. Le remplacement

La mise en évidence de sous-graphes particuliers (cf. figure 2) représentant les *patterns* des opérations les plus fréquentes (ajout vs. insertion, suppressions immédiate et différée, remplacement), a déjà été réalisée. L'identification de sous-graphes est utile dans l'analyse globale du graphe représentant le temps de l'écriture (Caporossi & Leblay, 2014)

C'est dans ce cadre que nous proposons 1) un programme dédié, *GenographiX*, pour mettre en évidence tout le travail génétique de réécriture, et 2) un corpus numérique de 10h 20 minutes d'enregistrement ; ce corpus est composé de deux tâches successives, la première de nature narrative (« depuis cette aventure… »), la seconde de nature argumentative (« Qu'est-ce qui est important pour vivre ensemble ? »). Il a été fait le choix de consignes à même de fonctionner auprès de publics très variés (âge, langue maternelle, niveau d'expertise). Précisons que la première reprend un protocole qui a déjà fait l'objet de recueil de corpus de textes auprès d'enfants et de futurs enseignants en formation (Garcia-Debanc et Bonnemaison, 2014), protocole proposé au départ par Charolles (1988) dans le cadre d'études de la cohérence textuelle. L'analyse des processus d'écriture enregistrée trouvera ainsi un point d'appui dans ces études consacrées aux produits.

Trois grands axes de recherche émergent alors : (1) le rôle des *opérations génétiques d'écriture-réécriture* qui sous-tendent toute activité scripturale sur papier comme sur écran (Fenoglio, 2012 ; Grésillon, 1994), (2) les différentes chronologies exhaustives qui caractérisent les écritures experte (vs. novice) et universitaire (vs. scolaire), (Bécotte *et al.*,2016 ; Leblay *et al.*, 2015), et (3) l'impact de la *visualisation* de cette chronologie sur la description et la reproduction de ces écritures dans le cadre de l'enseignement de l'écriture (Doquet & Leblay, 2014 ; Plane *et al.*, 2010). Les résultats que nous proposons, dans cette présentation, concernent particulièrement le phénomène de cohésion textuelle, tel qu'il apparaît, non pas seulement dans un texte produit, mais bien dans son déroulement chronologique. Apparaissent alors des retours ponctuels (qualifiés habituellement d'*erreurs, d'écarts, de dysfonctionnements,* tout simplement de *variantes*) pris sur le vif, en fonction de différents degrés d'expertise scripturale. Il s'agit de traces génétiques, rendues visibles, de phénomènes de retours dans la construction du sens (cohérence/cohésion) qui n'ont été jusqu'à présent observés et décrits uniquement dans des études basées sur des textes produits.

Ces trois axes nous permettent de souligner la place des visualisations numériques proposées par la génétique textuelle contemporaine dans des dispositifs conçus pour la formation à l'écriture : ces visualisations participent pleinement au travail de réflexivité, à celui de l'articulation entre savoirs théoriques et expérimentations de terrain, et enfin, à celui de la formation de praticiens-chercheurs (Brunel & Rinck, 2017).

Smelly London: visualising historical smells through text-mining, geo-referencing and mapping

Deborah Leem
d.leem@wellcome.ac.uk
Wellcome Trust, United Kingdom

Overview

Wellcome Collection is one of the world's major resources for the study of health and histories. Over the past few years Wellcome have been developing a world-class digital library by digitising a substantial proportion of their holdings. As part of this effort, approximately 5,500 Medical Officer of Health (MOH) reports for London spanning from 1848-1972 were digitised in 2012. Currently Wellcome holds the most comprehensive digital collection of the London MOH reports. Since September 2016 Wellcome have been digitising 70,000 more reports covering the rest of the United Kingdom (UK).

The MOH reports were published annually by the Medical Officers of Health employed by local authorities across the UK. These reports provided vital statistics and a general statement on the health of the population. MOH reports concentrated on reporting infectious diseases and resolving the problems as well as covering other areas of social responsibilities. (Chave, 1987) They have been long regarded as an important source for the 19th and 20th century history of Public Health and stem from reaction to infectious disease in the mid-19th century. Although there were attempts at standardisation, the reports display each MOH's interest, idiosyncrasies and particular strengths. Therefore, they also provide a particular perspective on the everyday lives of Londoners over several generations. No digital techniques have yet been applied successfully to add value to this very rich resource.

As part of the Smelly London project, the OCR-ed text of the MOH London reports has been text-mined using the Python programming language. Through text mining we produced a geo-referenced dataset containing smell categories for visualisation to explore the data. At the end of the Smelly London project the MOH smell data will also be available through other platforms such as Good City Life and Layers of London. This will allow the public and other researchers to compare smells in London from the 19th century to present day. This has the further potential benefit of engaging with the public. This is a collaborative, interdisciplinary project which will allow us to enhance and demonstrate the capabilities of innovative text mining tools we design to allow the automatic extraction of information from OCR-ed text. This paper presents the intended aims of the project; how this was achieved; an analysis of the findings; an interactive map of the results and a browser game of smells and disease.

Data and visualisation

As Roy Porter famously remarked that "todays history comes deodorised", sensory history is a relatively new historical approach. Historians rarely provide us an opportunity to hear, taste or smell the past. Medical historians have incorporated some aspects of sensory history into their research and explored the past belief that bad smells were causes of disease. However, there is very little research carried out covering this period.

Furthermore, smell has a great influence over how we perceive places and contributes to the construction of a place's identity (Quercia et al., 2015). During the 19th century the paranoia surrounding smells associated with poor hygiene heightened in many European cities (Reinarz, 2014). The Great Stink of 1858 resulted in the discussion of moving Parliament outside London for example. Despite the rise of germ theory (Pasteur and Koch) in the 1880s, concerns with disease-causing miasma (smells) did not disappear entirely. The MOH reports are one of the richest available sources on local public health administration and patterns of disease.

We enriched the text-mining pipeline with Natural Language Processing (NLP), including lemmatisation and part-of-speech tagging. The first iteration of the project has a feature to identify the category of the smells found by using a mapping table to work out the most common smell types. This step complements the close reading analysis and enables us to scale up the amount of information extracted from the texts. Our next research plan is to work on automatic identification of smell terms based on their contextual features to discover new categories that escaped previous classifications. This will allow us to identify smell categories in a data-driven fashion.

As the data becomes more structured, they can be more readily overlaid with other maps and images such as Charles Booth's London Poverty Map and 19th century disease maps. Having multiple layers will enable us to run various comparisons and assess if there are any correlations between smells and diseases as well as links to the socio-economic identity of areas in London.

During the first phase of the project we created a smelly map based on the number of smell hits to visualise the first set of results.

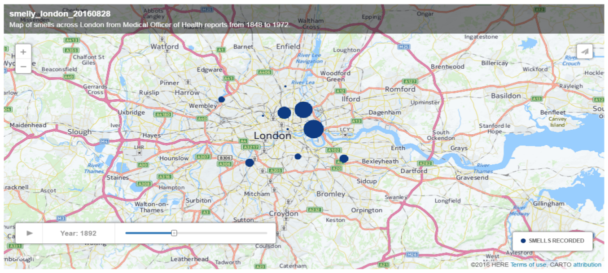

Figure 1. Smelly Map of London showing all smells

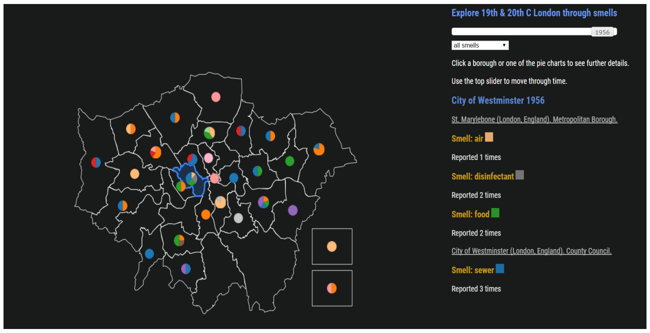
From the list of the existing London local authorities for the MOH reports we compiled, the geographic coordinates of present-day equivalents were extracted using an API. For the places that did not exist in the API, we manually added the geographic coordinates from Wikipedia. On the map each of the points marks the number of smells occurring at the centroid of each of the locations. We grouped the number of smells into sets of ten (e.g. 1- 10, 11 - 20) to avoid having giant points on the map for the places where there are almost 100 smells recorded. Finally, the map scrolls through the years. The data displayed in the mapping visualisation was obtained using text-mining via Python scripting. Python was the language of choice due to its high productivity rate and the fact that there are a large amount of third party libraries that offer highly useful functionality with just a few lines of code. For example, NLTK is a popular Python set of libraries that can achieve advanced NLP.

The next generation of map we produced during the second phase displays different smell categories that are colour-coded. The smell categories used for this map are Sewer; Waste-rubbish; Waste-excrement; Thames; Water; Food; Trade; Animal; Factory-fuel; Disinfectant; School; Air; Decomposition; Habitation; and Absence of smell. These categories were obtained through manual inspection of the data produced from searching for sentences containing smell-related words. In our codebase, we first analysed 5500 MOH London reports to find sentences that contained smell related words. Once the sentences were further analysed and categorised manually, the results were stored down into a local database by year, borough and a unique ID programmatically.



Explore 19th & 20th C London through smells

1956

all smells ▾

Click a borough or one of the pie charts to see further details.

Use the top slider to move through time.

City of Westminster 1956

St. Marylebone (London, England). Metropolitan Borough.

Smell: air 🟧

Reported 1 times

Smell: disinfectant ⬛

Reported 2 times

Smell: food 🟩

Reported 2 times

City of Westminster (London, England). County Council.

Smell: sewer 🟦

Reported 3 times

Figure 2. Smelly map of London showing smell categories

Computer programming can be used to perform tasks thousands of times faster than humans. In the Python code written to extract the data from the MOH reports, parallel processing was employed to speed up the running time of the program. Inside a computer there is a CPU which runs the tasks given by the program. Modern CPUs have multiple cores which allows the calculations to be run concurrently. In our project the CPU had four cores which allowed the running time of the program to be shortened by as much as three times. The next objective for the project is to scale up the size of the text-mining from 5,500 reports to over 70,000 reports covering the entire UK. In order to process such large datasets we are investigating the use of distributed computing resources such as Amazon Web Service (AWS). The code written for this project has been made open source under the MIT license along with documentation so that other programmers or researchers can use the codebase in their own text mining projects. The code has already been used in another project at Wellcome to investigate the idea of women's right to work during the 19th and 20th century London

Vision

The Smelly London project aims to bring together historical data with modern digitisation and visualisation to give us a unique, revealing and visceral glimpse into a London of the past and what it tells us about London today. Analysing the MOH reports tells the intimate narratives of the everyday experiences of 19th and 20th century Londoners through the 'smellscape'.

The Smelly London project provides a great opportunity to demonstrate how new knowledge and insights have risen from the use of powerful digital applications. This project will produce models that facilitate new kinds of humanities research. All outputs generated from the project will be open access and open source. Our data is available in a public repository on GitHub and other platforms.

Brumfield Labs, United States of America

The Civil War Governors of Kentucky Digital Documentary Edition (CWG-K) is a freely-accessible online collection of historical documents associated with the chief executives of the state, 1860-1865. Yet CWG-K is about far more than the five governors. Uniquely positioned to view, reflect upon, and intervene in the lives of thousands of people experiencing the traumas of civil war, Kentucky's chief executives stood at the intersection of public and private life during an era that transformed the nation. Collectively, their papers provide a multi-faceted lens through which we can recover and understand more fully the lives of countless men, women, and children who have been heretofore both historically undocumented and archivally silenced.

After five years of active editorial work, CWG-K published the facsimiles and transcriptions of 10,000 documents online in 2016. Driven primarily by keyword searches and limited metadata faceting, *Early Access* is a digital evolution of the printed letterpress edition and its index. The content is interpretatively rich and suggestive and can be queried and sorted in a number of ways, but the experience is still ultimately linear. The ultimate goal of CWG-K, however, is to create a digital research environment within which a user can encounter the past multi-dimensionally through the documents and the powerful annotation network that links the documents together through the individuals, institutions, and places found in the texts.

CWG-K's true impact on scholarship, however, is through annotation. To the extent possible given the restrictions and biases of the historical record, CWG-K is identifying, researching, and linking together every person, place, and organization found in its documents. This web consisting of hundreds of thousands of networked nodes will dramatically expand the number of historical actors, show scholars new patterns and hidden relationships, and recognize the humanity and agency of historically marginalized people. The network of identified and annotated people, places, businesses, government agencies, and military units, will come as close as possible to a historical reconstruction of mid-nineteenth century society as it was lived and experienced in wartime Kentucky.

In this document-driven historical ecosystem, users can explore intuitively—moving seamlessly through seemingly disparate historical themes, events, and topics; breaking into the plane of social and geographic space to understand the deep patterns that underlay the issues raised in a text or set of texts; and moving forward and backwards through time to put this reconstructed historical world in motion and understand patterns of ebb and flow.

Phase II of the project (September 2016-September 2017) extends the edition into network visualization. Instead of reinventing the wheel for all the different functionality that an editorial annotation tool needs to have, we have taken the best existing open-source tools and integrated them to achieve our goals. TEI-XML files are exported from the transcription and control file tool DocTracker, published on the Omeka-powered Early Access website, and checked into a Github repository. Research assistants use Hypothes.is to identify entities within each document on the Early Access site. The custom-built MashBill tool queries Hypothes.is for those annotations, allowing research assistants to identify references to entities and build relationships between initially coocurring entities and document biographical research from external sources. MashBill then uses the annotations and identifications to update the TEI documents automatically with the appropriate persName/orgName/placeName references and republishing them to Github.

In the open source tool MashBill, CWG-K makes an important contribution to network analysis in digital humanities. With a few exceptions network analysis is still dominated by network construction based on cooccurence of entities within documents. These entities are most frequently created by automated named entity recognition performed on plaintext. CWG-K researcher's close reading of documents to extract entities allows for much accurate identification of entities. The use of Hypothes.is makes such human-powered entity recognition far more scalable than traditional manual tagging of TEI-XML. Rather than using pure cooccurence MashBill allows relationships to be defined by researchers consulting resources outside the documents of the edition. These relationships are then visualized with a D3.js visualization which is deeply linked to both the documents themselves as well as the articles written during the course of entity and relationship research on the people, places, and things. The open source MashBill tool may be reused for any TEI/Omeka project to reduce the effort and improve quality of entity identification.

Since the Civil War Governors of Kentucky Digital Documentary Edition is a project of the Kentucky Historical Society, it has always focused on public access. The development of MashBill and integration of the network visualization produced with that tool into the early access website will enable the public to discover the lives and stories of everyday people who interacted with the offices of the governors. Our synthesis of approaches and technologies provides an example other projects can benefit from, showing how to leverage open source tools and standards to efficiently identify and build network visualization in public digital editions.

Tackling Innovation Networks with Smart Data: A Case Study of the Liquid Crystal Institute at Kent State University

Numerous innovations and inventions have been made by human beings in the past few millennia, providing the most important driving force for economic, social, and cultural developments. However, for thousands of years, credits for most of these innovations and inventions have been given to individual genius-inventors in almost all civilizations. While the Chinese credited the Yellow Emperor for the invention of the compass and Cai Lun for papermaking, the British and the Americans honored James Watts and Wright Brothers for the invention of the steam engine and aviation respectively. This genius-inventor approach dominated the history of innovation for centuries, partly because it was difficult, if not impossible, for both professional and amateur historians to access or process information beyond a limited number of individuals involved in those creative activities.

The predominant position of the genius-inventor approach has been challenged when computers and other technologies invented in recent decades drastically increased human capability in acquiring and processing large amounts of data. By taking advantage of these new innovations, some scholars began to reexamine various major innovations by expanding their scope to cover the complex interactions between genius-inventors and their peers. With this new approach, F. C. Moon discovered that many of those innovations were actually the products of extensive interactions between the well-recognized geniuses and large social networks around them. While shedding new light on many of the innovations done in the industrial age or earlier, this new genius-centered network paradigm still pays the most attention to the central role played by the genius-inventors. This tendency limits the paradigm's ability to explain the numerous innovations and inventions made in the past century or so that did not involve any well-recognized individual geniuses. The invention of the liquid crystal display is one of those cases. Widely used in making TVs, computers, stationary and mobile phones, various control panels, billboards, watches, clocks, microwaves, and many other products that affect every aspect of our daily lives, the liquid crystal display was invented and improved by a large number of researchers who worked closely with their collaborators along the way. This absence of a single "genius inventor" in the development of the liquid crystal display and many other innovations calls for a new approach, one that will focus squarely on the large number of researchers who formed various networks that made those inventions possible.

This paper approaches the invention of liquid crystal display from a new perspective. Instead of focusing on genius-inventors or genius-inventor centered networks, this study examines all the researchers at Liquid Crystal Institute at Kent State University (LCIKSU) as nodes in an institutionalized network, and explores their interactions among themselves as well as with outside collaborators. LCIKSU is chosen not only because it is the largest research institute in the field that has made unparalleled and sustained contributions to the invention of liquid crystal display, but also because it has kept comprehensive institutional records since its inception, which makes it relatively easy to trace and analyze the growth and adaptation of this unique network of researchers.

The examination of LCIKSU is based on extensive data drawn from various sources. The research group, whose members come from the disciplines of Library and Information Science, History, and Geography, has been given the access to all the available institutional records, including the LCIKSU annual reports, grant and patent applications, conference and exchange information, etc. All living directors of LCIKSU, incumbent as well as retired, have given long interviews, some meeting with the group multiple times. In addition, a large amount of data has been collected from various other sources such as the number of LCIKSU researchers' publications from Web of Science, their grant awards from the National Science Foundation website, and their patent awards from ProQuest. With the help of various available data processing tools, usable information has been extracted from all these historical records and turned into smart data, which is then used to accurately measure the contributions made by LCIKSU to the invention of the liquid crystal display, and to decipher the secret of its success as a complex network of researchers.

The careful study of the LCIKSU history reveals that the success achieved in the invention of liquid crystal display in the past fifty years has depended on the establishment and maintenance of a dynamic and productive network of researchers who collaborated closely with each other both within and beyond their own subfields or disciplines. Instead of looking for a genius inventor or becoming one themselves, the LCIKSU directors made every effort to recruit collaborating scientists to cover various sub-fields related with liquid crystal research. Some of the scientists, between a handful to a dozen over time, emerged as primary nodes in the network, producing the most paper publications, winning the most grants, and receiving the most patents. Usually leaders in their own subfields, these primary nodes not only worked with each other in conducting cutting-edge research, but also built their own sub-networks through various means and extended collaboration with other scientists throughout the university system, across the nation, and around the world. In order to better understand and illustrate the success of the LCIKSU researchers, the smart data collected on their papers published, grants received, and patents awarded is processed using various network analysis tools so that the degree and frequency of their collaboration can be measured and analyzed. The resulting assortativity, average clustering coefficient, degree centrality, closeness centrality, and between centrality indicators fully support the assessments made by individual researchers that the concentration of a large number of scientists, especially the primary nodes, at LCIKSU and the close collaboration among them have made it possible for these networked scientists to produce more and better research results at greater speed. After all, it is this sustained high level of research that has made LCIKSU the lead inventor of the liquid crystal display.

Joseph Schumpeter, one of the best-known economists in the 20th century, accurately observed in the early 1940s that technological progress was increasingly becoming the business of teams of trained specialists. However, team innovators who have played a growing role in innovation and invention have not received adequate attention. This examination of LCIKSU not only puts the researchers and their networks in the spotlight of the invention of the liquid crystal display, but also introduces a new approach that sharply focuses on the networks of scientists and extensively uses smart data. With further development and refinement, this new network-centered and smart-data-based approach has the potential to help narrow the existing gap in the study of modern history of innovation.

Teaching Empathy Through Virtual Reality

Amanda Licastro
amanda.licastro@gmail.com
Stevenson University, United States of America

In Philip K. Dick's Do Androids Dream of Electric Sheep the U.N. secretary proclaims, "[m]ankind needs more empathy" (1968). The poignancy of Dick's novel is its accurate expression of the social challenge of diminishing human empathy. The author offers empathy as the defining characteristic of humanity. As is often the case, science fiction foreshadows our future: longitudinal studies show decreasing rates of empathy in college students over the last three decades. If we believe that empathy is indeed a vital quality, then humanists are uniquely qualified to address this decline: extensive research suggests that empathy can be taught, specifically by reading fiction. Furthermore, preliminary trials indicate that virtual reality (VR) effectively evokes feelings of empathy in viewers. In both cases, the medium can provide the audience with access to situations outside of their everyday experience, offering a perspective into the lives of people unfamiliar to the reader/viewer. Take, for example, the work of documentary filmmaker Chris Milk that immerses the viewer in war torn villages in order to impact immigration policy (see "How virtual reality can create the ultimate empathy machine," 2016) or the content of the New York Times VR application which addresses a wide variety of social justice issues from all over the world. However, as critics such at Janet Murray rightfully argue, the impact of VR is dependent on the execution, which is still in development stages: "[t]he technical adventurism and grubby glamour of working in emerging technologies can make it hard to figure out what is good or bad from what is just new" ("Not a Film and Not an Empathy Machine," 2016). As the digital humanities have encountered with other emerging technologies - most notably data visualization techniques - these new forms need to be critiqued as they evolve (Drucker, 2012). Inviting students and educators to collaborate with industry professionals in the process of consuming, critiquing, and creating open access VR content creates the opportunity to design thoughtful immersive experiences that may address the decline in empathy in college age students. This presentation will explicate a study-in-progress devised to measure the pedagogical impact of VR content in combination with design thinking assignments used to combat desensitization and evoke empathy across the disciplines.

This research is supported with a case study of students in a series of linked courses at a small liberal arts college in Baltimore, MD. Students were exposed to VR content intended to increase their feelings of empathy for people who represent the "Other" in various ways, such as gender, race, ethnicity, and social class. This study was created through a cross-campus collaboration between faculty from the humanities, social sciences, and school of design alongside the theater director and librarians. Using empathy as the central question, each course integrated VR content and related readings into the curriculum. In each case, VR provided access to experiences not possible within the classroom space, for example an immersion into a refugee camp, a simulation of the human brain, and a documentary depicting gender bias across cultural contexts. The VR was scaffolded into each course in discipline-specific ways. For instance, the literature courses focused on readings that depict representations of virtual bodies in tandem with theory on posthumanism, particularly the work of Katherine Hayles and Donna Haraway. At the same time, the theater program produced The Nether by Jennifer Haley, which raises questions about the laws governing virtual spaces through depictions of pederasty and the murder of young children. Simultaneously, courses in psychology and human services integrated VR to discuss the impact of immersive content on social justice reform, and nursing courses looked at the application of VR for patient care and education. To varying degrees, this work was supplemented with readings on feminism, race theory, and disability studies in order to support discussions of "othering" with students. After analyzing the VR content in conjunction with the course materials, students were asked to design a VR experience intended to evoke empathy in the context of a discipline-specific audience. Additionally, members of a local VR company contributed as guest speakers and offered internships for interested students. Surveys were distributed at the beginning and end of the semester that prompted students to define, discuss, and debate empathy. At the end of each course students were interviewed to identify which methods of engagement increased their empathy toward people (in some cases characters) they felt were unlike themselves in significant ways.

As a part of this submission the syllabi and assignments will be shared. Ideally, the speaker will bring a VR headset and gaming laptop so participants can experience and consider how this emerging technology can evoke empathy by providing access to geographical, cultural, political, and biological content unfamiliar to the viewer. The goal is to receive audience feedback on the first stage of this study in order to improve and refine the methods before executing the plan on a larger scale. This study is IRB approved and student consent will be obtained for any student work that is presented.

Flexible Computing Services for Comparisons and Analyses of Classical Chinese Poetry

Chao-Lin Liu
chaolinliu@gmail.com
National Chengchi University, Taiwan

Introduction

As for many civilizations, poetry is an essential part of Chinese literature. Poetry has influenced the development of the literature and language of both classical and vernacular Chinese. Certain of the words that we use today can be tracked all the way back to the Shijing (詩經/shi1 jing1/ -- We show the pronunciations of Chinese characters in Hanyu Pinyin followed by their tones. Here, /shi1/ is for "詩" and /jin1/ is for "經".), c. 1046BC. Research on Chinese poetry is thus instrumental for understanding Chinese culture, and a lot of invaluable results have been accumulated over the past thousands of years from the study and analysis of Chinese poetry.

The availability of digital tools and resources enable researchers to compare and analyze the poetry from certain perspectives that were hard to achieve in the past. In many cases, we can verify the claims of previous researches with solid data, and, in others, we may enrich our understanding of the poetry.

The accessibility of increasingly larger datasets strengthens our research potential. In earlier stages of digital humanities, pioneers focused their work on Tang and Song poetry (it is beyond our capacity to list all previous research in this proposal, and we provide just two samples: Hu and Yu, 2001; and Lo et al, 1997) . Now, we can access digitized texts of poems that were published in the periods from 1046BC to modern days.

Software tools allow us to study the data from a wide variety of perspectives in an efficient way. Search engines and information retrieval techniques (Manning et al, 2008) help us extract relevant texts from a large dataset. Then, researchers can employ domain knowledge for advanced studies with the use of additional tools.

In this paper, we showcase research results that we achieved by handling the available data with existing tools in flexible ways. We collected nine representative corpora of Chinese poetry, one each for a major dynasty in Chinese history between 1046BC and 1644AD. We list the corpora in Table 1, where we assign an acronym to each corpus for ease of reference (See Notes, 1). We also show their Chinese names (**Collection**) and the periods of publication (**Time**). A collection for the Qing dynasty is unavailable yet because an editorial committee is still working toward the completion of this very challenging goal (Zhu, 1994). Excluding the punctuation marks that were added by the data providers, we have more than 16.5 million characters (see Notes, 2) in the corpora.

Acronym	Collection	Time	Acronym	Collection	Time
SJ	詩經	1046-476BC	**CV**	楚辭	475-221BC
HF	漢賦(文選)	202BC-420AD	**PT**	先秦漢魏晉南北朝詩	Before 589AD
CTP	全唐詩	618-907AD	**CSP**	全宋詩	960-1279AD
CSL	全宋詞	960-1279AD	**YSX**	元詩選	1271-1368AD
LCSJ	列朝詩集	1368-1644AD			

Table 1. The corpora of poetry of 1046BC-1644AD used in this study

By flexibly integrating and migrating tools to offer new functions, we can provide researchers with opportunities to investigate Chinese poetry from new perspectives. In the first example, we show a new way to compare the ways that poets use words in their poems. In the second, with our own tools, we can find shared collocations and patterns of poems in different corpora, and this capability allows us to study and compare the styles of individual poets and their dynasties.

	LSY	LB	DM	DF		LSY	LB	DM	DF
春風;秋風	14;2;16	72;26;98	18;11;29	19;30;49	春草;秋草	0;0;0	15;12;27	2;1;3	13; 5;18
春水;秋水	2; 3; 5	3;10;13	4; 5; 9	8;12;20	春色;秋色	0;1;1	9;11;20	3;6;9	20; 7;27
春月;秋月	0; 0; 0	0;40;40	0; 0; 0	0; 4; 4	春來;秋來	4;1;5	0; 3; 3	2;6;8	8; 6;14
春日;秋日	2; 2; 4	2; 1; 3	3; 1; 4	13; 5;18	春光;秋光	2;1;3	6; 0; 6	2;3;5	9; 1;10

Table 2. The frequencies of selected words used in poems of LSY, LB, DM, and MF

A Multi-Faceted Comparison

Jiang (2003) compared the usage of "wind" (風/feng1/) and "moon" (月/yue4/) in the poems of two of the most famous poets, Li Bai (李白/li3 bai2/) and Du Fu (杜甫/du4 fu4/), of the Tang Dynasty (which existed between 618 and 907AD) by comparing the contents of selected poems. Liu et al. (2015) listed the frequencies of frequent words that used "wind" and "moon" in Li's and Du's poems. The numerical comparison shows the differences of the poets in a vivid way.

The software tools can be designed so that we can inspect not just the original poems or the raw statistics about the original poems, but also more complex comparisons.

Table 2 lists the frequencies of frequent bigrams (again, see Notes, 2) that appeared in the poems of four poets, i.e., LSY (for 李商隱/li3 shang1 yin3/), LB (for Li Bai), DM (for 杜牧/du4 mu4/), and DF (for Du Fu) (Note: 李商隱/li3 shang1 yin3/ and杜牧/du4 mu4/ are two very famous poets of the Tang Dynasty)

These bigrams are special in that they are formed by concatenating either “春”/chun1/ or “秋”/qiu1/ with another character, and they represent something related to “spring” and “autumn”, respectively (when used individually, “春”/chun1/ or “秋”/qiu1/ typically represent “spring” and “autumn”, respectively– see Notes, 1). The numbers “14;2;16” in the row of “春風;秋風” and in the column for “LSY” indicate that we have 14 and 2 of LSY’s poems in which “春風” and “秋風” were used, respectively. “16” is the sum of 14 and 2.

The statistics in Table 2 shed light on the differences in word preferences among the poets. Note that the samples in Table 2 are limited, and that a close reading is necessary to reach any further interpretations. Despite these limitations, we still can explore comparisons from various perspectives. “春風” and “秋風” are the most common choices among all of the rows (They appeared 192 times, i.e., 16+98+29+49). In contrast, “春月” and “秋月” were not as popular (They appeared only 42 times, i.e., 40+2), and none of the poets used “春月”. In terms of personal preference, “春風” appeared in LB’s poems three times often than “秋風”. The results of LSY are similar to those fore LB, but DF seems to prefer “秋風” instead (The ratio for “春風”: “秋風” is 72:26 for Li Bai, 14:2 for Li Shang Yin, and 19:30 for Du Fu).

The entries that have “0”s can be linked to strong personal preferences. For instance, LB did not use “春雨” and “春來”, while he did use “秋雨” and “秋來”. DM is special in that he did not use “春天” or “秋天”.

We can provide different ways to compare the styles of poets, e.g., converting the frequencies in Table 2 to probabilities of seeing the same word in the poems. By building a vector space representation (Manning et al, 2008) for each poet, we can calculate a score of similarity for style as in many other researches.

Networking Names and Words

In addition to comparing the words of the famous poets, we may also attempt to compare the words and themes of the poems that were produced by friends. We can look up whether two poets were friends in professional databases like the China Biographical Database (CBDB) (Fuller, 2015). A database like the CBDB can also provide alternative names of poets so that we may algorithmically find friendships among poets by checking their writings (Liu et al, 2015). After identifying a group of poets who were friends, we can investigate whether the words, styles, and themes of their poems are related. A procedure such as which we used to produce statistics like those in Table 2 may be useful.

A poet may be influenced by another poet even though they were not personally acquainted. It is believed that poets of the same school of poetry (we use “school of poetry” to translate “詩派” /shi1 pai4/) share similar styles or words. Hence, information about the membership of a school of poetry provides a starting point for an investigation.

We may also search for poets who shared the same words and collocations in their poems as a clue for an indirect friendship. Given the millions of characters in our corpora, we need to have an efficient mechanism to identify poems that shared collocations and patterns (Liu and Luo, 2016), and using our own tools, we can precisely identify words that were shared by poems of different poets and of different dynasties (see Notes, 2).

The ability to identify the shared words between individual poets also automatically allows us to compare the patterns that are frequently shared between any two corpora. In Figure 1, two words are connected if they frequently co-occurred in poems. Part (a) shows the shared collocations in poems in the YSX and CTP, and (b) is for the shared collocations in poems of the LCSJ and CTP. The differences between (a) and (b) indicate that the highly shared collocations changed from dynasty to dynasty, i.e., from Tang to Yuan and from Tang to Ming. A collocation with a different word may suggest that the word contributes a different sense in the poems, e.g., “春風-桃花” and “春風-何處” in (b), and this can be verified by reading the poems that used these collocations. Sometimes, the links suggest replaceable words, for instance, both “千里” and “萬里” can go with “十年” in both (a) and (b). It should be noted that the collocations often carry information about the imagery of the poems.

Concluding Remarks

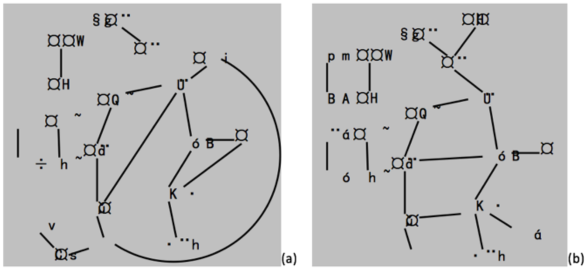

Figure 1. Frequently shared collocations between poems of two corpora (a) YSX and CTP (b) LCSJ and CTP

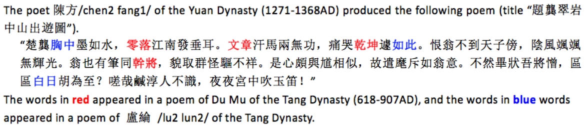
We briefly discussed how we studied two new research problems by flexible applications of our tools. The new tools provide new forms of data as in Table 2 and Figure 1 for interesting and useful research. We are working toward an in-depth understanding of Chinese words by studying when, who (Liu and Luo, 2016), and how the words (see Figure 2) and their collocations and patterns were used in Chinese poetry, and our tools will help domain experts study challenging and interesting problems about it (Liu, 2016). We also hope that the information and visualization that we have found and established for words can contribute to an interactive version of the complete Chinese lexicon (Cheng et al, 2016).



The poet 陳方/chen2 fang1/ of the Yuan Dynasty (1271-1368AD) produced the following poem (title "題龔翠岩中山出遊圖").

"楚龔胸中墨如水，零落江南發垂耳。文章汗馬兩無功，痛哭乾坤遽如此。恨翁不到天子傍，陰風颯颯無輝光。翁也有筆同幹將，貌取群怪驅不祥。是心頗與馗相似，故遣麾斥如翁意。不然畢狀吾將憎，區區白日胡為至？嗟哉鹹淳人不識，夜夜宮中吹玉笛！"

The words in **red** appeared in a poem of Du Mu of the Tang Dynasty (618-907AD), and the words in **blue** words appeared in a poem of 盧綸 /lu2 lun2/ of the Tang Dynasty.

This research was supported in part by the grant 104-2221-E-004-005-MY3 from the Ministry of Science and Technology of Taiwan, the grant USA-HAR-105-V02 from the Top University Strategic Alliance of Taiwan, and the Senior Fulbright Research Grant 2016-2017.

Notes

1. 詩經 /shi1 jing1/, 楚辭 /chu3 ci2/, 漢賦(文選) /han4 fu4 (wen2 xuan3)/, 先秦漢魏晉南北朝詩 /xian1 qin2 han4 wei4 jin4 nan2 bei3 chao2 shi1/, 全唐詩/quan2 tang2 shi1/, 全宋詩/quan2 song4 shi1/, 全宋詞/quan2 song4 ci2/, 元詩選/yuan2 shi1 xuan3/, 列朝詩集/lie4 chao2 shi1 ji2/

2. It is important to briefly mention the differences between Chinese characters and words for readers who are not familiar with the Chinese written language. Characters are the basic units for Chinese words. A Chinese word can be formed by one or more characters. For instance, "水"/shui3/ and "果"/guo3/ are two characters. They can be used individually to represent "water" and "results", respectively. A word consisting of *n* Chinese characters can be called an **n-gram** in linguistics, e.g., "水果" is a **bigram** that represents "fruit". While the majority of the words in vernacular Chinese are bigrams and trigrams, the proportion of unigrams in classical Chinese is very large.

Introduction and Main Findings

Chinese characters are the basic units for Chinese words, and a Chinese word can include one, two, or more characters. Many characters can function as words in Chinese. For instance, “人文” represents “humanities”, and “人” and “文” are characters that carry their own meanings. Words that contain two, three, and more characters can be referred as *bigrams*, *trigrams* and other appropriate names for *n-grams*. Chinese does not separate words with spaces like English, so a reader must “segment” a character string into words to understand Chinese statements.

Mandarin Chinese has evolved over the past thousands of years (Yong and Peng 2008). Documents written in current vernacular Chinese contain a large number of bigrams and trigrams, while texts of classical Chinese (sometimes referred to as “literary Chinese”) contain many more unigrams. In the Academica Sinica Balanced Corpus (ASBC), unigrams contribute only 2.1% of word types, but constitute a 44.8% share of word tokens (“types” refers to distinct words in linguistics, e.g., “today is today” has three tokens and two types). In contrast, bigrams and trigrams together constitute 82% and 53% of the word types and tokens, respectively.

Zipf discovered that the relative frequencies of words are inversely proportional to their ranks in Chinese and English documents (Zipf, 1932) in his endeavor to establish a theory of *Principle of Least Effort* (Zipf, 1949). Many researchers have attempted to find the parameters in the Zipf-Mandelbrot distributions (see also, Piantadosi, 2015) for English and for Chinese (see Ha et al, 2003) many have explored extensions and applications of the law (see Altmann et al, 2002).

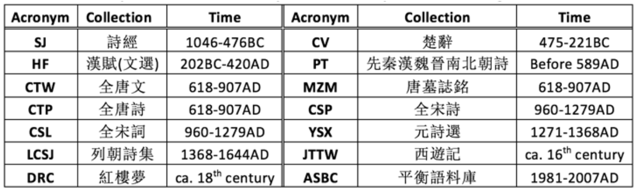
Previous research works for Chinese have focused mainly on fitting the Zipfian distributions to Chinese corpora. Some considered a distributed sample of corpora (Altmann et al, 2002), and others confined their analysis to a specific corpus (Deng et al, 2014). Some researchers have pondered on explanations for why the statistics of languages obey the Zipfian distributions (Powers, 1998, and Piantadosi, 2015).

We examined the Zipfian distributions of 14 collections of Chinese texts that were published from 1046BC (the year when the Zhou Dynasty (周朝) of China began) to 2007AD, and we found that the genres and epochs of the collections influence the distributions. The majority of our collections are poetic works written in classical Chinese. We also included official documents of the Tang Dynasty, novels of the Ming and Qing dynasties, and news articles of modern days.

The character distributions for the corpora of poems of 618-1644AD (the period stretching from the Tang dynastry to the Ming dynasty) exhibit strikingly similar Zipfian distributions. In contrast, the character distributions of the three genres of corpora that were all written in the Tang dynasty are distinguishable, although the characters frequently which are used in these documents are very similar. The word distribution of the ASBC differs significantly from other character distributions, indicating the importance of differentiating character- and word-based models of Chinese.

Corpora and Comparisons

For ease of references, we assigned an acronym for each of the 14 corpora, and show their names in Chinese (**Collection**) and periods of publication (**Time**) in Table 1.



Acronym	Collection	Time	Acronym	Collection	Time
SJ	詩經	1046-476BC	CV	楚辭	475-221BC
HF	漢賦(文選)	202BC-420AD	PT	先秦漢魏晉南北朝詩	Before 589AD
CTW	全唐文	618-907AD	MZM	唐墓誌銘	618-907AD
CTP	全唐詩	618-907AD	CSP	全宋詩	960-1279AD
CSL	全宋詞	960-1279AD	YSX	元詩選	1271-1368AD
LCSJ	列朝詩集	1368-1644AD	JTTW	西遊記	ca. 16th century
DRC	紅樓夢	ca. 18th century	ASBC	平衡語料庫	1981-2007AD

Table 1. The corpora used in this study include texts published during 1046BC-2007AD.

The corpora consist of representative literature that has been published since 1046BC. In particular, we have at least one collection for each of the major dynasties that existed before 1644AD. The majority of our collections are of poetic works (we consider SJ, CV, HF, PT, CTP, CSP, CSL, YSX, and LCSJ collections of poetic works) which fact lends itself to the study of the effects of genres on the character distributions. A collection of poetic works for the Qing Dynasty (which lasted from 1644 to 1912AD) is unavailable because an editorial committee is still working on its production (Zhu, 1994).

The corpora contain more than 42 million characters, excluding the punctuation marks that were added into the corpora by the data providers. When counting the characters, we also exclude characters that cannot be shown on ordinary computers. The frequencies of such rare and obsolete characters are not large, so ignoring them will not affect the statistical properties reported in this study.

Only the ASBC was segmented and the segmentation was verified by human experts. Hence, we can inspect its character and word distributions. The other corpora were written in classical Chinese and we do not have a reliable way for segmentation, so we will only analyze the character distributions.

We created charts that are based on the typical form of Zipf’s law:

$$\log\left(\frac{f(w)}{N}\right) = k - \alpha \log\left(r(w)\right)$$

where w, $f(w)$, and $r(w)$ denote a word, its frequency, and rank in a corpus, respectively. The rank of the most frequent word in a corpus is 1. N is the size of the corpus, and k and ✔are constants.

Observations and Discussions: Influences of Genres and Epochs

The generalizability of the Zipf’s law is the main reason that it has attracted the attention of many researchers. It can be applied to various natural distributions including those of part-of-speech of words (Wang et al, 2012), city sizes (Anderson and Ge, 2005), and corporal revenues (Chen et al, 2008).

Figure 1 shows the Zipfian curves when we consider the character distributions of all of the 14 corpora. We intentionally plot the curves in one chart, although this makes the individual curves undistinguishable. Although the curves are not linear, which is common as reported in the literature, the curves show a consistent trend, suggesting a common regularity that is shared by Chinese texts that were produced over the period of 3000 years.

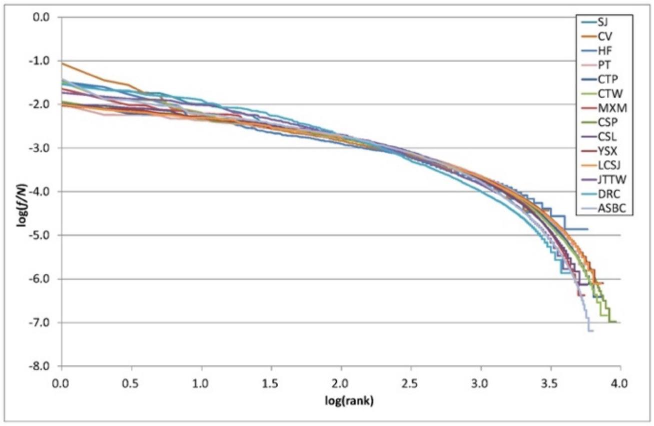


Figure 1. Zipfian curves of 14 corpora suggest a common trend. (Character distributions)

Instead of treating the 14 corpora as a single corpus to fit the resulting distribution for Zipf's law, we examined the curves to investigate possible factors that influenced the positions of the curves. In Figure 2, we show the curves of lyrics ("詞" /ci2/) and poems ("詩" /shi1/. The left halves of the curves overlap almost perfectly, which strongly indicates that the poetic works share very close statistical characteristics.

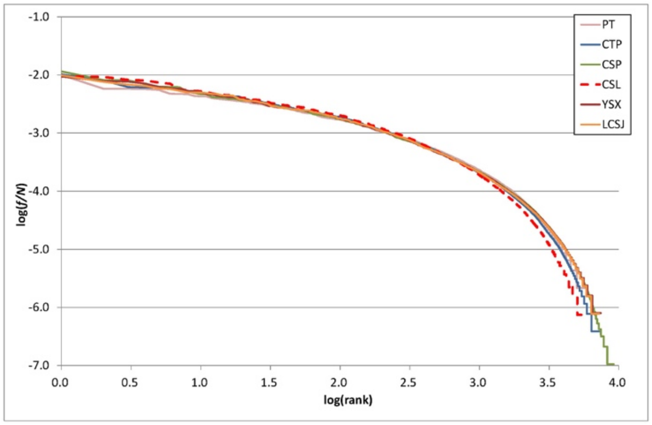

Figure 2. Zipfian curves of the corpora of lyrics (the red dashed curve) and poems (the rest) are strikingly similar. (Character distributions).

Table 2 lists ten most frequent characters found in each of the corpora and for which the curves are plotted in Figure 2.

Corpus	Ranks									
	1	2	3	4	5	6	7	8	9	10
PT	不	無	風	有	人	雲	之	何	日	我
CTP	不	人	山	無	風	一	日	雲	有	何
CSP	不	人	一	無	山	有	風	來	天	日
CSL	人	風	花	一	不	春	無	雲	來	天
YSX	不	人	山	風	一	雲	天	日	有	無
LCSJ	不	人	風	山	一	花	日	雲	有	無

Table 2. The most frequent ten characters in poems and lyrics remaining stable over time

The lists are very similar, and, out of the 60 characters in Table 2, there are only 16 distinct characters (some of which are homonyms, for which only one pronunciation is provided). In fact, we can compare the most frequent characters of any two corpora, e.g., the CTP and the CSP, to further investigate their similarity (Chen et al, 2012), and we found that the most frequent 1700 characters in the CTP and the CSP are the same characters.

Not all of the corpora of poetic works have similar curves. We added the curves for the SJ, CV, and HF in Figure 3, and it is evident that these new curves do not overlap with those in Figure 2 very well. The poetic works in the SJ, CV, and HF were produced very much earlier than those listed in Figure 2.

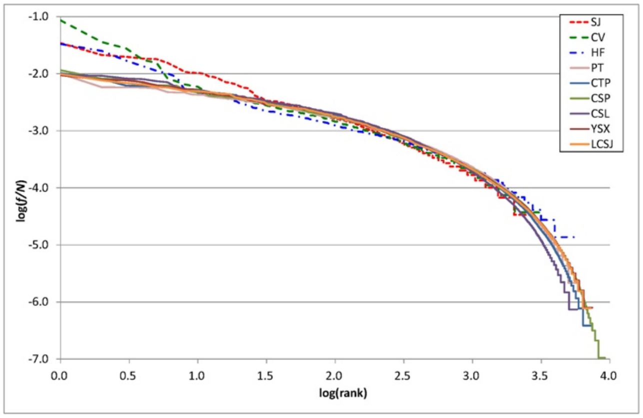

Figure 3. Curves for ancient poetic works (SJ, CV, and HF) do not coincide with those of later poems.

While the time of the production of the corpora affects the Zipfian curves, the curves for corpora that were produced in the same dynasty may not be the same. The CTW, MZM, and CTP are three different types of works that were all produced in the Tang Dynasty. We compared the most frequent characters shared by the CTP and CTW, and found that the sets of their most frequent 2000 characters differ only in three characters. Despite such an extreme overlap, their curves in Figure 4 suggest that genre affects the character distributions.

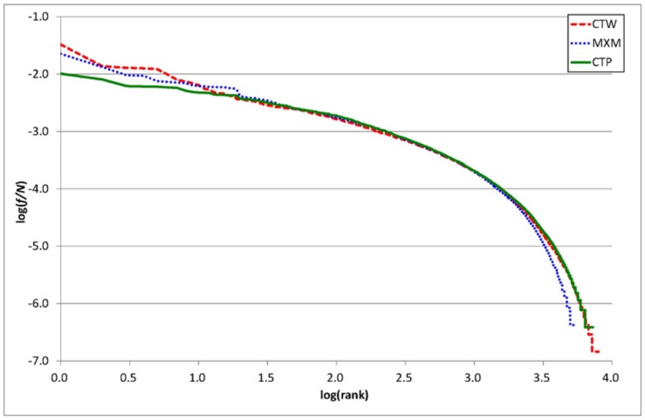

Figure 4. Curves of corpora that belong to the same dynasty but of different genres deviate from each other.

Given the above observations, one may have expected that the curves for the novels that were published in the 16th and 18th centuries, i.e., the JTTW and DRC, will deviate from the curves for the earlier poems, as the curves in Figure 5 show.

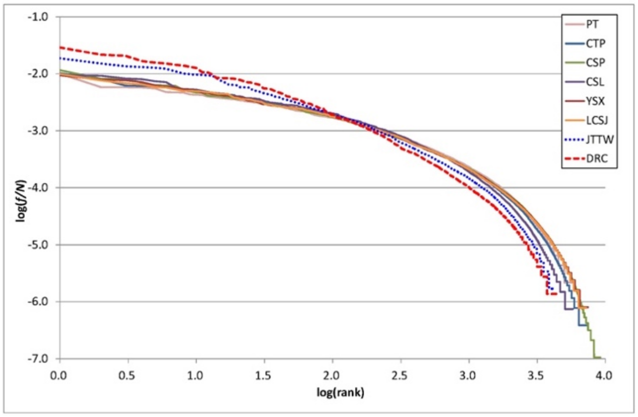

Figure 5. Curves of corpora that contain novels of 16th and 18th century (JTTW & DRC, respectively) deviate from the curves in Figure 2.

Character vs. Word distributions

We considered the character distribution when we analyzed the contents of the ASBC in Figure 1, where we found that the character distributions of the vernacular and classical Chinese texts show a reasonable common trend. The ASBC contains documents that were written in vernacular Chinese, so we must also analyze its word distribution, and Figure 6 shows the curves for both the character and word distributions.

A chart like that of Figure 6 can mislead one to infer that Chinese texts do not conform to Zipf's law. It is well accepted that the number of Chinese characters is limited, although there is no consensus about the exact number of characters. In contrast, there is virtually no limit on the number of legal Chinese n-grams. As a result, the sharp downturn of the character distribution and the intersection of the two curves in Figure 6 are expected, and this can be observed in languages other than Chinese in some special settings (Montemurro, 2001). We should examine the Zipfian curves on the same basis, e.g., character or word, while considering cultural factors that may influence actual language usage.

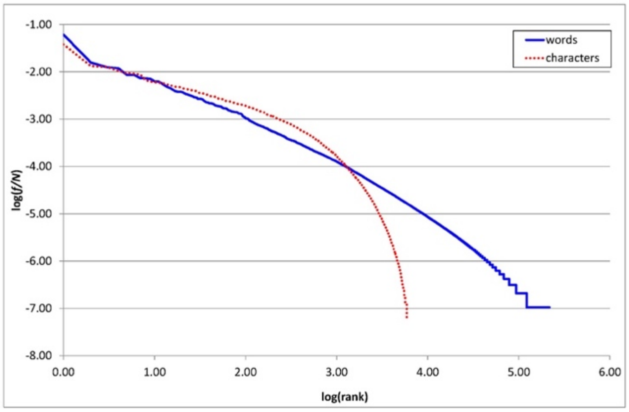

Figure 6. Word and character distributions for the ASBC differ significantly.

Concluding Remarks

We have judged the similarity between the Ziphian curves based on the visual closeness, though we can quantify the degree of similarity when desired (Hu and Kuo, 2005). Researchers have noticed the deviations of Zipfian curves at the high- and low-frequency ends (Hu and Kuo, 2005, Rousseau and Zhang, 1992) and tried to find density functions that fit the data. The statistics at the high-frequency ends of the curves are evidently more reliable. We focused on the deviations at the high-frequency ends of the curves, and discussed how the deviations in these regions may relate to the genres
and epochs of the corpora, employing the lists of most frequent characters of the corpora as extra supports.

Introduction

The structured repositories in cultural heritage have become the most used infrastructure for knowledge management towards different kinds of systems and platforms, ensuring a complete interoperability and reachability of data. Thanks to the semantic web paradigm, we are able to manage and enrich our data using formalisms and data standards: examples include digital libraries and digital archives, as well as SPARQL endpoints. However, the fragmentation of data produced by different kinds of mapping methodologies and different representations of the knowledge to be managed leads to some discrepancies between domains and results obtained during data retrieval.

A typical example is the study of an inscription, which will be addressed by linguists with regards to language; by philologists with regards to its text; by historians as a primary source; by archaeologists as material testimony of events and by conservationists as a piece of matter to be preserved and restored. In that scenario, semantic interoperability and standardization are two fundamental elements as they guarantee the circulation of knowledge inside a shared environment.

This paper aims to present the methodology followed in the Nurcara Project concerning resource integration and knowledge management. Nurcara consists of a dataset (almost 300 records) composed of textual Latin documents from the Medieval Age that provide historical context for the area of Monteleone Rocca Doria in Sardinia (Sassari, Italy) between the 11th and 15th centuries. Starting from an SQL database, our solution focuses on the development of a semantic framework solution able to both automatically map the relational dataset in CIDOC-CRM ontology on-the-fly and aggregate the knowledge from different repositories or endpoints. This method aims to semantically enrich Nurcara's dataset with external resources from the same domain, such as SPARQL-endpoint and Linked Data resources.

Nurcara project

Nurcara started from the following directive: to make accessible to the community the huge amount of published and unpublished medieval documents about Monteleone Rocca Doria that until now have been only accessible from the researchers.

Thanks to a collaboration between the Spanish Ministry of Cultural Heritage and the University of Sassari, it has been possible to start archival research of historical documents from the National Archive of Cagliari, the Historical Archive of Alghero and the General Archive of the Crown of Aragon in Spain. During the research almost 300 medieval documents in Latin, Catalan, Castilian and Sardinian were cataloged and stored in a MySQL database. The documents dated from the 11th to 15th centuries and related to Monteleone Rocca Doria (SS), which made them useful for defining the socio-economic context of the area during the medieval age.

Interoperability and semantic enrichment

The interoperability and semantic enrichment of the data represents one of the most important milestone of the project. It is crucial to publish the dataset in an accessible format with Semantic Web technology such as SPARQL or Linked (Open) Data.

In order to reach our goal, we started with the conceptualization of the entities from the relational database and the definition of the semantic schema. CIDOC-CRM has been chosen as the main reference model.

CIDOC-CRM is an ontology created in order to offer "definitions and a formal structure for describing the implicit and explicit concepts and relationships used in cultural heritage documentation". The CIDOC-CRM model is a semantically rich model used to conceptualize the cultural heritage domain composed of 86 classes and 138 properties. The purpose of CIDOC-CRM is to provide a common definition for heterogeneous forms of information, and to enable their integration despite possible semantic and structural incompatibilities.

In order to translate data stored in the Nurcara relational database to the CIDOC-CRM ontology (expressed in RDF-Resource Description Framework) we have used the D2RQ tool that will provide an automatic mapping between the relational database and the CIDOC mapping schema.

D2RQ is a popular mapping platform for publishing relational data as a virtual RDF graph. It enables legacy relational databases to be exposed on the Web, according to the principles of Linked Data, and to be included in the Semantic Web. D2RQ exposes relational databases as SPARQL endpoints. It translates SPARQL queries posed on a virtual RDF graph to SQL queries posed to the underlying relational database.

Mapping Solution

The mapping process started with the definition of the main entities useful for the definition of the conceptual model directly from Nurcara's database:

- Document (E84 Information Carrier)
- Author (E39 Actor)
- Issue place (E53 place)
- Issue date (E50 Date)
- Type (E55 Type)
- Title (E35 title)

We chose these entities as a starting point for the mapping activities because from a conceptual point of view, they cover the minimum knowledge representation useful for the description of the documents from Nurcara's database. Furthermore, with the aim of defining a more suitable (event-oriented) semantic model with respect to CIDOC-CRM ontology, we defined some "abstract" entities that are outside the structure of Nurcara's database, but are present as classes in CIDOC ontology:

- Dataset (E73 Information Object)
- Event (E5 Event)
- Activity (E7 Activity)

Here, the use of the abstract classes as an intermediate layer allowed us to guarantee a more detailed and coherent conceptualization of the proposed model with respect to CIDOC-CRM ontology. Then, thanks to definition of the "Dataset" as E73 Information Object, it is possible to extend the proposed model with CRMdig (developed as a compatible extension of ISO21127) application profile from CIDOC-CRM ontology, which allows us to encode metadata about the steps and methods of production of digitization products.

The defined conceptual schema has been directly implemented as a mapping file (using D2RQ syntax) in D2RQ in .ttl format, in order to ensure the live mapping process between Nurcara dataset and CIDOC-CRM ontology.

In order to enrich and extend the dataset, we have also considered in the mapping.ttl schema other Linked Data end-points such as DbPedia or Geonames, which are specified by prefix and reachable via a proper SPARQL query directly from D2RQ SPARQL end-point.

Data accessibility

As previously stated, after the mapping process, the data are expressed and exposed as RDF graph based on CIDOC-CRM structure.

Hyperlinking

The D2R server supports hyperlink navigation by providing links on the RDF and XHTML levels. Any RDF triple whose object is a dereferenceable URI can be seen as a hyperlink. This is how resources published by the D2R Server are interlinked with other databases and external RDF documents. To aid discovery of related resources, D2R Server includes an rdfs:seeAlso triple with every resource description that points to an RDF document containing links to other resources produced by the same ClassMap (In our case, DbPedia or Geonames). If resources are identified with external URIs, then an additional rdfs:seeAlso link points to a local RDF/XML document that contains everything the database knows about the resource. By dereferencing the external URI and by following the rdf:seeAlso link, RDF browsers can retrieve both authoritative and non-authoritative information about the resource.

Search

The D2R Server allows the users to query non-RDF databases using the SPARQL query language over the SPARQL protocol. Queries are executed against a virtual RDF graph representing the complete database. Query results can be retrieved in the SPARQL query result as XML or in SPARQL/JSON serialization.

Conclusion

In spite of progress in the area of RDF storage, a large quantity of data is still stored in non-semantic repositories or relational databases.

Nevertheless, especially in the domain of the humanities, we are seeing growth in the use of semantic platforms for the management of digital data as a common method of knowledgement management. The CIDOC-CRM ontology is one of the most used in digital humanities. In this proposal we want to show how a specific dataset as Nurcara can be successfully integrated under the much more generic CIDOC-CRM structure, and how the knowledge can be easily enriched thanks to LOD integration. In order to reach the goal, the scalability and the full customization offered by the D2RQ server has played a crucial role.

The future development of this project concentrates on the integration of the Description Logic algorithm and reasoning system with the purpose of increasing resource discovery with respect to the domain utilized by the Nurcara project.

Mapping concepts and authors from 20th century Portuguese magazines of ideas and culture

Magazines of ideas and culture constitute a very unique and exceptional set of sources, whose richness comes from an ample participation of intellectuals and artists, including some of the most influential individuals of their time. The fact that Fernando Pessoa first published most of his work in these periodicals clearly illustrates their importance (Andrade, 2003). These authors' prolonged participation, over issues published during long periods of time, allows us to capture and understand the movement of ideas and the diversity of their voices, in a continuous process of debate and update.

The periodical press played a very strong historical role in France (e.g., Charle, 2004; Pluet-Despatin et al., 2002), Italy (Frigessi, 1979), the United States (Tebbel and Zuckerman, 1991), and Brazil (Luca, 2011; Martins, 2012), to mention a few examples. The history of magazines in Brazil is particularly interesting to us, due to the very direct relationship between Brazilian and Portuguese intellectuals, who often wrote in the same publications (Guimarães et al., 2013).

In Portugal, all prominent intellectual movements used the periodical press, and specifically magazines, as a place of reunion, where they shared, discussed, and made their ideas public. In the first half of the 20th century the diversity of published magazines was as ample as the diversity of artistic, cultural, intellectual, and political movements. Magazines were used not only to reach other intellectuals but also a wider audience, with a commitment to establish a strong and informed public opinion, in search of what many contemporary authors believed to be "a universal rationality present in every person" (Andrade, 1999: 31, translation ours). The press was, among other things, a territory of political struggle and intervention.

For almost two decades now, the research group Free Seminar of History of Ideas (Seminário Livre de História das Ideias, n.d.) has been working on building a comprehensive and extensive database of some of the most important 20th century Portuguese magazines of ideas and culture. The project Magazines of Ideas and Culture (Seminário Livre de História das Ideias, Revistas de Ideias e Cultura, n.d.) has taken a multidisciplinary approach from the very beginning, encompassing knowledge from fields such as history of ideas, library science, and information science. Its aim was to build a relational database containing exhaustive information on authorship, quoted authors and works, subjects, concepts, and geographical names, for all articles contained in these publications.

One of the main methodological aspects of the project was the segmentation of the traditional "key-words" field in two: subjects and concepts. The key-word was deemed a too insufficient and imprecise instrument for obtaining a comprehensive understanding of the underlining ideas and ideological frameworks contained in these magazines.

To avoid the use of divergent criteria in establishing what could be considered a concept, a conceptual thesaurus, for use by researchers, was discussed and developed by the team beforehand. The first step in this process was to reach a consensual definition of the two relevant operative fields; in very broad terms, a concept was considered abstract, whereas a subject was deemed the materialization of an idea (e.g., Koselleck, 2004; Skinner, 2005 and Castro, 1996: 11-21, for a somewhat different theoretical approach). For example, in an article containing the concept "war," acceptable accompanying subjects – limited by actual article contents, of course – are any and all specific armed conflicts, as well as all the thoughts and ideas that can be produced on "war." We seek to determine concepts from a comprehensive, rather than explanatory, perspective. This means that, in any given article, all structuring concepts mobilized by the author, in accordance with the conceptual economy underlying the discourse, are relevant and thus collected.

Utilizing a conceptual framework also makes it possible to record the use of a concept without a verbatim textual mention of the word (Lisboa, 2015: 133-145). The need for a critical understanding of the texts made the use of tools for text recognition (OCR) inadequate. As such, all the input information is collected and validated by researchers.

The definition of the conceptual thesaurus followed principles of parsimony, consistency, and clarity, avoiding redundancies and repetitions, while at the same time favouring common criteria and language comprehensibility for all users:

> *"While making no claim to absolute denotation or universality, and agreeing with the fundamentally subjective use of concepts, we believe that the use of a large number of concepts is in fact ubiquitous, in parallel with the difference between language and speech. However, notwithstanding the differences between language and the uses of language, we must be able to achieve some level of systematization, as found in most dictionaries and similar works of reference*."

The resulting conceptual network constitutes one of the strongest virtues of the project, allowing for a clear delimitation of the general and specific terms that structured thought as a representation of the world, a phenomenon which can be found in magazines of the same political, cultural, or artistic movement. The set of reciprocal concepts in the conceptual map for each movement will allow a clear understanding of the fundamental ideas and thoughts that motivated their authors.

It should be noted that our project does not aim to classify information, but rather to provide a comprehensive reading of the sources. Our output is meant to be the result of a critical analysis of the source and an interpretation of its contents, grounded in the fields of History of Ideas and Conceptual History, and not a mere blind or neutral collection of terms and names. The database is not intended to replace the source, but instead to aid navigation through its complexity, providing meaning and structure to the included corpus of discourses, and highlighting the underlying programmatic and doctrinarian aspect of these magazines.

Our presentation proposal focuses on the magazine *A Águia*, a *monthly magazine of literature, art, science, philosophy, and social critique*, as stated in the subtitle, published between 1910 and 1932. This was the main organ of the republican Renascença Portuguesa, one of the most noteworthy intellectual movements of 20th century Portuguese history. For its 205 issues, published over the five series that make up the magazine's complete collection, 1,903 articles were indexed, and the collected data includes 403 single authors, 4,299 quoted names, and 1,033 concepts, among other descriptors.

We will apply network analysis to our data (Wasserman and Faust, 1994; Scott, 2000; Carrington, Scott and Wasserman, 2005), and intend to focus on the most important authors, i.e., those that have written the most articles for *A Águia*. Connecting individual article authors with the authors quoted in their texts should provide a visual map of intellectual networks, highlighting influences between authors and their ideas, thoughts, and intellectual background. Using information on quoted names will bring to light the shared and individual references of these authors, providing a visual network of the most influential names featured in their participation in the magazine.

We also intend to trace conceptual networks for a few selected authors. By observing the interaction of concepts used by a given author during a long period of time, an illustration of the course and evolution of their thoughts and ideas will hopefully manifest. In addition, observing the connections between concepts used by different authors (which concepts are used simultaneously more often, for example) can highlight profound or subtle differences in their intellectual background. Finally, confronting the two stages of our analysis – quoted authors and concepts – will provide a clear and vivid image of each author's views and discourse.

We believe that quantitative analysis of qualitative information can be a very powerful instrument if there is a strong consistency in the information being analysed. It can bring to light new relationships between authors, conceptual frameworks, or even conceptual transitions within a single author. Shifting from a narrative of intellectual dialogue to a visual movement of thought and ideas can be a powerful tool for obtaining an original and comprehensive image of the structures of thought underlying the intellectual production of a given period, through a particularly significant medium, i.e., magazines.

The tool developed by our research group "is an invitation for the reader to remember that knowledge is, foremost, an exercise of imagination, since the universe of questionable content and the scope of viable answers are both meticulously expanded." (Andrade, n.d.)

Modelling Literary Scholarship

The availability of digitised full-text resources, as well as bibliographical data in standard database format, has recently opened a new chapter in the sociology of literature by revaluating empirical approaches and data-driven scholarship. The road to this “empirical turn” in literary scholarship has been paved by such scholars as Franco Moretti (2005, 2013) and Matthew Jockers (2013), who showed how empirical data like bibliographical records, annotations, title words, genre categorization, etc., may help in generating new knowledge about literary periods. This approach gathered its momentum as other works exploring the possibility of using such data to answer particular research questions emerged. Due to the shortage of space we will name just a few that have the most influence on this paper, dividing them into three research strands. Firstly, the use of bibliographical data for statistical inferences on literary processes, e.g Bode’s (2012) rereading of Australian literary history through the data from AustLit (Australian Literary Bibliography). Secondly, the study of author co-occurrences and mutual references, e.g. visualising literary circles on the basis of such data by Long and So (2013a, 2013b). Thirdly, the application of topic modelling to uncover pertinent issues in literary scholarship, e.g. Goldstone and Underwood’s analyses of the evolution of American literary scholarship on the example of PMLA (2012) and seven major literary journals (2014). In combining those approaches into a macroanalytical study of *Teksty Drugie*, we also adopted the rationale introduced by the 40th anniversary internet edition of *Signs*, a literary journal dedicated to feminist criticism.

Aim

The aim of this study is to apply macroanalytical methods to trace the chronology of transformations of Polish literary studies using the example of *Teksty Drugie.* We hypothesise that the collection of papers published in a leading academic journal on literary scholarship can serve as a reliable approximation to chronological changes and/or breaks in Polish literary theory at the turn of the 20th century. We will first trace the topics present in the journal and then analyse them in diachronic perspective. We will focus on the influence of extra-textual events and phenomena on literary scholarship.

We believe that 25 years is a sufficient timespan to observe linguistic differences which are not caused by regular language change. Other projects conducted by the authors of this paper show that a language change (in Polish) typically spans many decades rather than a mere 25 years (e.g. Eder & Górski, 2016). Furthermore, we deal with conventionalised language of scholarship, so the use of certain terms often relates to a given paradigm rather than to a language in general. Nevertheless, we are aware of possible changes of meaning of keywords while interpreting topic models.

Material

Teksty Drugie is a Polish literary journal dedicated to literary scholarship. It has been published since 1990 by the Institute of Literary Research of the Polish Academy of Sciences. It focuses on literary theory, criticism and cultural studies, while also publishing articles by authors from neighbouring disciplines (philosophy, sociology, anthropology). The journal publishes monographic issues dedicated to particular topics or approaches within literary and cultural studies. All those features make it a good example for exploring the vicissitudes of Polish literary scholarship.

The corpus consists of the entire collection of papers published in *Teksty Drugie* (excluding letters, surveys, notes, etc.) in the years 1990–2014 (2,553 texts, 11,310,638 words). The material covering the years 1990–1998 was digitised, OCR-ed, and then manually edited, in order to exclude running heads, editorial comments, and so forth. Obviously, some textual noise – e.g. a certain number of misspelled characters – could not be neutralised. The material from 1999 onwards was digitally-born, but even though a small number of textual issues might have occurred. We believe, however, that distant reading techniques are resistant to small amounts of systematic noise (Eder, 2013).

Given the nature of Polish, which is highly inflected, lemmatization was necessary for a reliable processing of texts. The corpus has been lemmatised with LEM 1.0. (Literary Exploration Machine) developed by CLARIN-PL (see: Piasecki, Walkowiak, Maryl 2017).

Method

To scrutinise the formulated hypothesis, we applied one of the methods of information retrieval that recently attracts a good share of attention in Digital Humanities circles, namely topic modelling in its classical variant known as Latent Dirichlet Allocation (LDA). The method, introduced by Blei (2012), allows for finding co-occurring cohorts of words that presumably reveal (latent) semantic relations.

The experiments were performed using a tailored script in the R programming language, supplemented by the package 'stylo' (Eder et al., 2016) for text pre-processing, and the package 'mallet' (McCallum, 2002) for the actual LDA analysis. A bimodal network of the relations between topics were produced using the software Gephi (Bastian et al., 2009).

Topic modelling relies on the assumption that particular topics are defined by words co-appearing in a given context. Hence, the definition of "context" is crucial to allow for any reliable observations. A few different solutions have been suggested (e.g. Blei, 2012; Jockers, 2013). In our approach, we did not split input texts into smaller samples, which was motivated by the fact that the vast majority of the studies published in Teksty Drugie are rather short.

Other parameters used in the study included: a stop word list containing 327 words (mostly function words, numerals, and very common adverbs), 100 topics extracted in 1,000 iterations, with the obvious caveat that this choice was arbitrary.

Results

A general overview of the obtained results shows a few interesting patterns. Firstly, we analysed and categorised the topics on the basis of their predominant words. The categories are as follows: literary theory (e.g. literature, fiction, text), poetics (e.g. verse, novel, short story, rhetoric) and methodological approaches (e.g. deconstruction, comparative literature, postcolonial studies, psychoanalysis); history of literature (e.g. romanticism, contemporary poets) and cross-cutting research themes (e.g. death, politics, literacy).

A thorough exploration of such models requires a topographical visualisation capable of showing the connections between various topics, which often share a key word (cf. Goldstone and Underwood, 2012). The network (Fig. 1) is too large to be adequately rendered in this paper (a higher resolution image of Figure 1 is available online), yet even without the knowledge about concrete topics presented, we may see (partly thanks to ForceAtlas2 layout, which highlighted this feature) that groups of topics in our corpus are concentrically distributed. This onion-like distribution allows us to distinguish between the central topics (i.e. those who appear in many different papers) and those who appear less often or sporadically and hence are not particularly well-connected with other topics. For instance, in the geometrical centre of the network we may find topics and words pertinent to literary scholarship: literature, literary, comparative literature, national literatures, Jewish studies, fiction, together with some names of contemporary authors. Outliers are also interesting, and could be assigned to 3 groups: (1) expressions in foreign languages, (2) particular research topics or discourses which introduce quite a hermetic language, not shared in other topics, (3) noise (e.g. word bits generated through some errors in OCR).

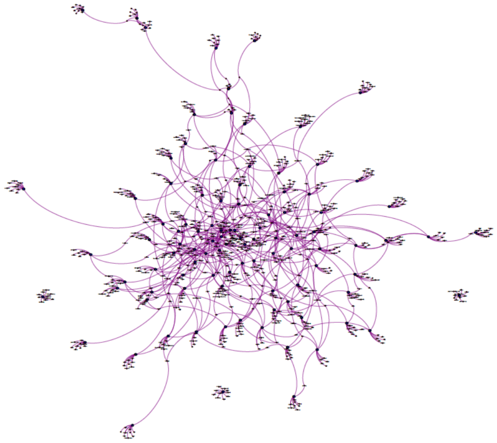

Figure 1. Relationships between topics in Teksty Drugie.

Yet it has to be noted that even the most accurate rendering of the topical distribution is still only a static snapshot insensitive to changes. In order to see the evolution of topics, we need to visualise them on a temporal axis. Due to a shortage of space we present here only a few examples, to show the application of our method. All dot plots are presented below with a trend line based on two period moving average.

Fig. 2 represents the gradual shift of interest from more literature-oriented approaches, to the cultural ones. Both red (topic 19: literature, literary, writer, work) and green (topic 5: literature, research, theory) seem to be dominating until approx. 2007, when the blue line (topic 49: culture, cultural, social) overtakes the green line for the first time. Three years later it becomes the dominant approach, marking the shift in the overall content of Teksty Drugie.

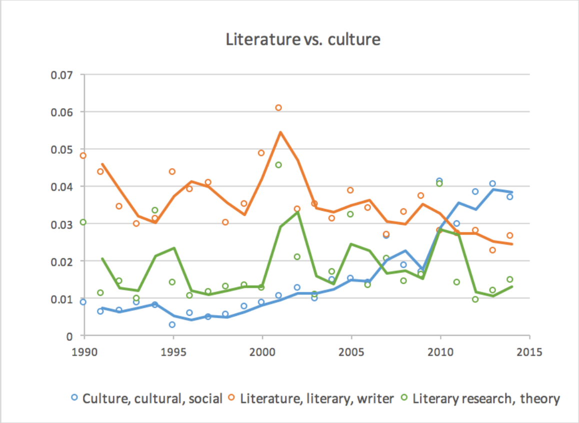

Fig. 2. A temporal distribution of three topics related to literature and culture.

Topic analysis allows us to not only trace the evolution of the journal itself but also to see how the real-world events shape the topics undertaken by literary scholars. Fig. 3 shows the influence of the political transformation in Poland on the content of Teksty Drugie. We see a similar pattern in trends of all topics presented: grey (topic 60: power, society, state, fight, war, law), red (topic 36: political, communism, Polish People's Republic), blue (topic 7: Polish, Pole, national), yellow (topic 94: censorship, exile, novel, positivism, country, London, political). All of them are quite important in the early 1990s and the interest gradually fades until the end of this decade. The spikes around 2001/2002 are caused by the publication of monographic issues which make certain topic more dominant. E.g. Issue No.1-2/2000 was dedicated to socialist realism hence the spike of "communism-related" issue in that year.

This trend shows how political events (namely the transformation and forming of the new democracy) are dominating even the literary scholarship. It could be also the case that more politically charged issues (e.g. history of censorship in Poland) could have been published only after the fall of the communism, hence so many articles in that period.

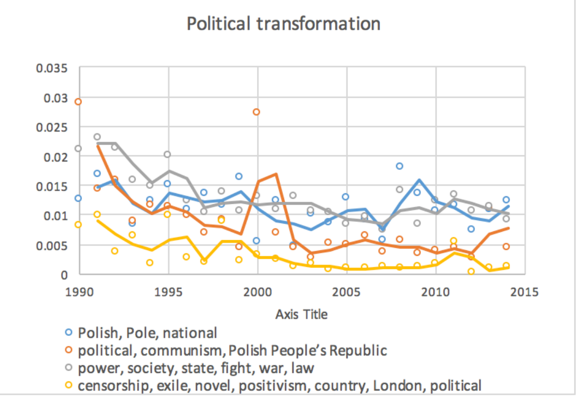

Fig. 3. Temporal shift of topics related to politics.

The last trend we would like to discuss is the emergence of the Holocaust studies in Teksty Drugie. As we can see in the Fig. 4, the red trend line (topic 59: Jew, Jewish, antisemitic) is visible on the fairly same level all through the 25 years, whereas the blue one (topic 18: testimony, Holocaust) is virtually non-existent until 2001.

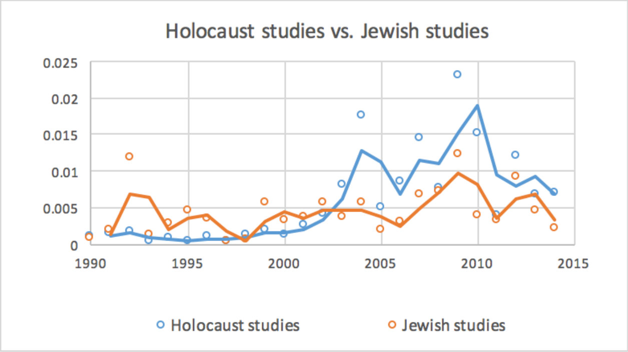

Fig. 4. Temporal distribution of topics related to Jewish studies and the Holocaust.

This sudden boom can be linked to the publishing of the Polish edition of Neighbors by Jan Gross (2000) and the investigation into the role of Polish civilians in the genocide perpetrated in the city of Jedwabne during the World War II. This case opened a long process of re-investigating the troubled Polish-Jewish past, which could be traced also in the issues of *Teksty Drugie*.

Conclusions

In this study we tried to show how extra-textual events influence the content of literary scholarship on the example of Holocaust studies and political transformation, which entailed the prevalence of topics related to politics, power, society, state, and communism in the early 1990s. In the subsequent studies we plan to compare the results of topic modelling with bibliographical data in order to check whether the dominance of a certain topic stems from the large number of scholars who pursue it, or if it instead depends on the fact that a small group of authors published more often than others.

Acknowledgements

The authors wish to thank Dr Tomasz Walkowiak for his extensive help with cleaning and lemmatizing the corpus.

Mapping the Meshwork of the Independent Media Arts

Lindsay Kistler Mattock
lindsay-mattock@uiowa.edu
University of Iowa, United States of America

During the late-1960s and early 1970s, independent media artists imagined a network of organizations that would support the production, distribution, exhibition, preservation, and study of film and video not only in the known centers of activity (New York City and San Francisco), but across all regions of the United States. By 1980 the Media Arts Center Movement had gained significant momentum leading to the establishment of the National Alliance of Media Arts Centers (NAMAC). These centers included national players, such as the Museum of Modern Art in New York City, along with regional organizations like the Rocky Mountain Film Center and Pacific Film Archives, and other metropolitan organizations like Pittsburgh Filmmakers (one of the oldest remaining active media arts centers). These organizations provided services for artists – funding and equipment rentals – and to the surrounding community – screenings, coursework, and study collections. NAMAC changed its nomenclature in the mid-1990s to the National Alliance of Media Arts and Culture, yet the legacy of the media arts center movement continues today. Mapping the Independent Media Community (MIMC) is a project that seeks to illustrate the impact of the individuals and organizations that were part of this larger movement to support the development of independent media arts, not just in the United States, but across the globe.

MIMC is currently in its first phase of development, generously funded by a Major Project Grant from the University of Iowa. Partnering with Carnegie Museum of Art (CMOA) in Pittsburgh, Pennsylvania, the MIMC team at the University of Iowa has worked in conjunction with CMOA's Time-Based Media Project (funded by a grant from the A.W. Mellon Foundation) to digitize and provide access to records contained with the CMOA's Film Section Archives (spanning 1970-2002). The MIMC prototype is based on the data contained within the *Film and Video Makers' Travel Sheet* and *Film and Video Makers' Directory* published between 1973 and 1987. The *Travel Sheet*, a monthly publication, served as a social networking tool for media artists and media arts centers. At no cost, artists could publish booked tour dates along with a general sense of their travel schedule, while organizations posted the contact information for their internal programmers, indicating a willingness to host makers. Over the years, the *Travel Sheet* grew to include sections for new works available, film festival announcements, and other advertisements of general interest to film and video makers. The *Directory*, published in 1978 and 1979 included the information of all of the individuals and organizations subscribing to or listed in the *Travel Sheet*. From its humble beginnings as a single hand-typed 11x17 sheet of paper, the publication grew to include thousands of individuals and organizations from all corners of the globe. Using the data from the *Travel Sheet,* this first phase of the MIMC project serves as a prototype for a much larger and more robust application that will visualize data from a wide variety of sources in order to provide a more comprehensive understanding of the Media Arts Center Movement in the United States as well as global independent media production, distribution, exhibition, preservation, and study.

The MIMC database (built using the University of Sydney's Heurist Academic Knowledge System) currently holds only a few years of the *Travel Sheet* data. However, even this small subset of the data MIMC illustrates that the Media Arts Center Movement was indeed successful in building a wide-reaching network of organizations and individuals. The image below represents a sample of data from New York-based artists reported between 1973 and 1975 in the *Film and Video Makers Travel Sheet* (data from 26 artists residing in New York City and New York state).

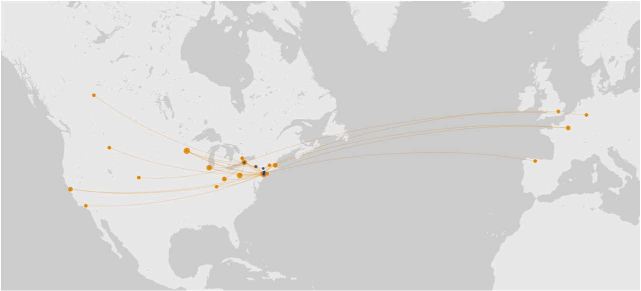

Figure 1: Selected event data from the *Film and Video Makers Travel Sheet* 1973-1975 (created with Palladio).

In the above image, the artists' home address is represented in blue while the event location is represented in orange (the event locations are sized according to the number of events, 99 total). This visualization demonstrates the connections between organizations and individuals emerging from the data in the *Travel Sheet.* Here we can see the beginnings of a network that extends beyond the United States and into Europe and Canada. As data entry and analysis continues, the data promises to demonstrate a global network of artists and media arts organizations as a sample from the 1979 *Film and Video Makers' Directory* illustrates, below.

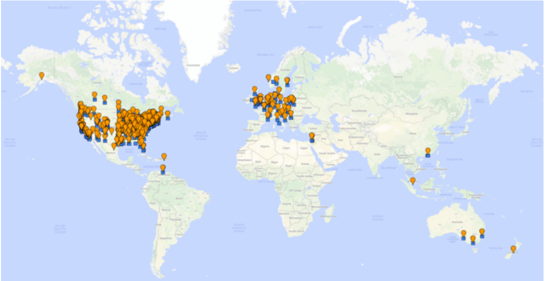

Figure 2: Organizations (square) and Individuals (teardrop) from the 1979 *Film and Video Makers Directory*

While the term network was the preferred terminology of the Media Arts Center Movement, this is an overly simplistic understanding that masks the complexity of the MIMC data. Anthropologist Tim Ingold argues that the lines of a network are connectors, static points joining two nodes, that presume an absolute connection that does not fully illustrate the complexity of the relationship. In contrast, Ingold offers the concept of the meshwork, suggesting that these lines are not connectors, but the "lines of becoming" from Deluze and Guattari's rhizome (Ingold, 2013: 132). These lines do not meet – the nodes in the network map instead represent knots and entanglements in the meshwork, places where lines emerge and diverge rather than connecting in absolutes. The meshwork, like the rhizome, affords multiple narratives and entry points; it offers no hierarchy or structure. MIMC seeks to offer this alternative mapping of the meshwork – the entanglements between artists, distributors, museums, governmental bodies, local communities, and countless other actors in the fabric of the independent media arts.

Unlike other digital humanities approaches to cinema and media history, like Jeffrey Klenotic's Mapping Movies, MIMC provides access not only to a representation of the history of the independent media arts, but access to the archives that hold these traces as well. The MIMC data model includes the provenance for each discrete data point in the database, linking individual records back to the primary source material from which it was derived. These connections will afford opportunities to link directly to the digital archives that hold the digital surrogates as these records, allowing MIMC to serve as an extension of these archival collections as a digital finding aid of sorts. In this way, MIMC is enfolded in the archives; the project does not derive-from but is entangled-with the archival organizations and other sites that hold the history that MIMC seeks to represent, continuing to build the meshwork that entangles the various organizations and individuals represented in the visualizations. In locating and documenting these archival traces, MIMC provides an understanding not only of the historical unfolding of the independent media arts and Media Arts Center Movement, but of the archivalization of this history as well – the project itself becoming further enmeshed and entangled in the very history that it seeks to uncover.

This brief paper will introduce the MIMC project and discuss the development of the MIMC application as well as the potential impact of the project as a Public Digital Humanities resource for scholars and for the archives that collect and provide access to the primary source materials from which the MIMC data is derived. In addition to the database and visualizations, by preserving the source information for each record and linking to the digitized archival records (or archival finding aids), MIMC links the archive of the independent media arts that is distributed across archives, personal collections, the active and inactive organizations that are part of this vast meshwork. While there is still much work to be done, MIMC promises to provide widespread access to historical data that can be reused and re-imagined beyond the initial bounds of the project.

Chatbot Based Content Discovery: Faulknerbot in the Archive

Aaron Mauro
mauro@psu.edu
Pennsylvania State Digital Humanities Lab
United States of America

Introduction

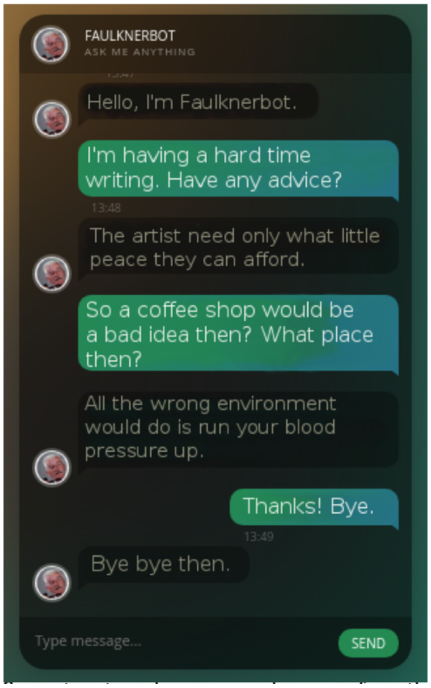
In March of 2016, the failure of Microsoft's proto-type chatbot, Tay, was not just a technological failure. It was a disciplinary failure. It was a failure of an indus-try leader to adopt a critical perspective when build-ing systems in a complex cultural and social environment. Tay, which stands for "thinking about you," was the name given to an artificial intelligence chatbot for Twitter that was quickly corrupted by users and began spewing racist, sexist, and homophobic slurs. Pundits quickly leapt to conclusions about the political beliefs of internet users, but these same pundits failed to un-derstand that this hacking of Tay was in fact a critique of chatbots in the real world. Users of Twitter were exposing a fundamental error made by the Microsoft development team. Because the system learned directly from user input without editorial control or content awareness, Tay was quickly trained to repeat slurs by users eager to embarrass Microsoft.

This moment in technological development makes for an interesting anecdote, but it also represents the moment that chatbots entered the public conscious-ness and became nothing less than the future direction of a unified interface for the whole of the web. Of course, chatbots captured imaginations in the 90s as well. Systems like Cleverbot, Jabberwacky, and Splotchy were fascinating to play with, but they had no real application. Today, text based AI has been identified as the the successor to keyword search. No longer will we plug in keywords into Google, comb through lists of text, and depend on search engine optimization (SEO) to deliver the best content. Search will be around for a long time, but in the near future much more content will be delivered through text based messenger services and voice controlled systems. We've seen the early stages of this change in products like Amazon's Alexa, Apple's Siri, Google Now, and Microsoft's Cortana. There are now bots embedded within common platforms like Slack, Skype, and Facebook Messager. We are now approaching a world that Apple envisioned in 1987 with a mockup system called the "Knowledge Navigator" that sought to give users an interactive and intelligent tool to access, synthesize, present, and share information seamlessly.

Humanities in the Loop

We are likely decades away from a true "knowledge navigator," but the second generation of these chatbots are now in development. The company that developed Siri for Apple is now in the final stages of development on a system called Viv (Matney). Viv is the first viable company to produce a unified interface for text and speech based AI assistants. Facebook is testing project M within its messenger app to allow users to issue commands, access services, and make purchases through text input (Hempel). The remarkable thing about M is that Facebook has built a system with "humans in the loop." This means that when a service is accessed, perhaps by purchasing movie tickets, a human will fine tune the AI generated results for each transaction. There is currently an understanding within the machine learning community that human assisted training of these systems produces more accurate results but will also train more robust systems go-ing forward (Biewald, Bridgwater). The current need for human in the loop systems means that we are at a crucial moment for humanists to lend their experience and critical abilities to the development and training of AI systems. In the field of machine learning, training a system to answer humanities based problems will show how these systems succeed or fail, but they will also demonstrate the value of the humanities in a digital world. If the purpose of the humanities is to better understand what it is to be human, training AI to answer philosophical, historical, or cultural questions will help us understand our experiences as we become more accustomed to intelligent systems in our lives. Grappling with AI, whether it is in a mundane consumer exchange or in matters of grave ethical importance, is rapidly becoming a practical problem in our lives.

With humanists in the loop, we will better under-stand the social and cultural contexts in which these systems appear and avoid the regrettable failure of systems like Tay in the future. We are currently on the cusp of a revolution in the applicability of natural language understanding, artificial intelligence, and conversation based interfaces design. These technologies will have ranging consequences socially, culturally, and economically in the coming decade, but these technologies are also deeply connected to the social and cultural contexts in which they appear. My goal is to train machines to be humanists. It is the literary critic's ability to close read complex philosophical, historical, and artistic meaning that these systems lack. It is the ability of the historian to contextualize political and technological change within the breadth of human progress. It is the dramatist's ability to understand performance and dialogue that will animate our conversations with computers. The digital humanities are well situated to make the most of NLP techniques and find culturally significant training sets.



FAULKNERBOT

ASK ME ANYTHING

Hello, I'm Faulknerbot.

I'm having a hard time writing. Have any advice?

13:48

The artist need only what little peace they can afford.

So a coffee shop would be a bad idea then? What place then?

All the wrong environment would do is run your blood pressure up.

Thanks! Bye.

13:49

Bye bye then.

Figure 1: Faulknerbot interface with basic query and response

Method: Conversational Data Retrieval

Biographical and archival material has been used to train a system to allow a conversation with the famed American author William Faulkner. I will present a system trained with nearly all the interviews that Faulkner has given. Author interviews are an excellent training set because the questions asked by the interview anticipate user interests and model a conversational style of response. The interviews collected during Faulkner's visit to the University of Virginia were instrumental in building this tool. The applications for such a system are numerous. A conversation with Faulkner might benefit a creative writing student in the midst of writer's block. A chatbot offers a more inviting interface for a general public. Most importantly, Faulknerbot will represent a novel form of content discovery for student researchers. Once a user has developed a chat history worth exploring, Faulknerbot's responses link to original archival materials for research purposes.

Current systems have come a long way from the toy-like chatbots that populated the web in the late 90s. After a preprocessing stage using word2vec, which vectorizes the bag of words, this model uses Tensor Flow to generate two complementary neural networks that encodes and decodes inputs and responses. This model has only recently been made accessible to non-computer science researchers recently by Google open sourcing Tensor Flow. is not based on the retrieval based model using a rule based expressions, with a heuristic to determine intent and draw from a predefined response. This is not a simplistic tree model based on nested "if/then" statements. Instead this uses a generative model. This generative model uses sequence to sequence learning with neural networks. This model links words statistically to determine "flows" of meaning through a word vector. Geoff Hinton calls this a "thought vector." In other words, this is an end-to-end model that remains open. Rather than a retrieval method, which limits the scope of the conversation, this system dynamically learns and allows for a retention of what has been said. The generative model allows for this context based discussion without resort-ing to an enormous conversation log. In Tensor Flow, this operates on a Long Short Term Memory (LSTM) network. As I've said, the sequence to sequence model is based on two neural nets. One is an encoder, which encodes input data from the user. The decoder model determines the reply by generating the output, which need not echo the size of the vector. This thought vector generalizes input and links to a target response. This is not a "feed forward" neural net. It is a recurrent neural net that continually retrains on the training data, which is often the marker of a true "deep learning" system. This model makes no assumption about purpose or predetermined output. It simply reinforces relationships between thought vectors over time. There is a deeply emotional resonance that is carried through conversation. The blurring of lines between social media, search, and messaging will result in a seamless and unified interface for digital technology. Driven by the mobile space's demand for streamlined UI design, we will become more reliant on assistive technologies that can anticipate, learn, and adapt to user input.

Conclusion

It is important for the humanities to anticipate this new cultural space. When the Google autocomplete system was introduced to search, there were many cultural commentators decrying the loss of independent thought and the potential for entrenching damaging stereotypes (Postcolonial). The loss of critical awareness and even just the ability to spell. Technology that offends our sense of what it is to be essentially human is usually the next important media type. Chatting with machines tends to cross such lines. There are practical uses for remedial education and composition studies. A functioning Teaching Assistant Bot capable of answering questions about deadlines, assignments, and course policy would be welcome by most educators. Indeed, an AI TA has been developed recently, but it is unclear if this system can be trained on any course material or was custom built for this class (Maderer). Generalizing these systems is a difficult task, to be sure. The newly open sourced Tensor Flow machine learning library can answer questions derived from a training set of just over a million words. When we consider the limits of machine learning in intelligent assistants, scholarly communication through chat interfaces is certainly the next logical step. However, these systems require humans in the loop. They require thoughtful and critical reflection. They require an attention to depth and nuanced meaning. They require a humanist in the loop.

Credit Allocation with the Social Knowledge Timeline

Aaron Mauro
mauro@psu.edu
Pennsylvania State Digital Humanities Lab
United States of America

Introduction

Humanities scholarship is becoming increasingly collaborative, participatory, and public facing. As humanists take up digital tools to conduct and share research, larger teams are needed to complete ever more complex computational tasks. When blending these heterogeneous teams--which may include faculty, librarians, staff, undergraduates, graduate students, postdocs, and community contributors--humanists have an ethical responsibility to offer a fair and transparent accounting of research activities. Tracing the evolution of research contributions is necessary for a range of issues facing digital scholarship such as authorship allocation, promotion and tenure, and reports to funders. The allocation of credit and authorship is an increasingly thorny issue for teams with a range of possible roles and a variety of research outputs and media types. There is, however, a large amount of data being generated by these teams that is capable of describing and measuring the contributions made on a variety of platforms and by multiple team member and community partners.

Despite our inheritance of social and collaborative tools, many of these systems elide the nuance and process of humanities based research. Knowledge creation is not merely a function of how much code is produced. New knowledge is often the result of a key insight made by a team of students, staff, and faculty. These insights are generated in a complex and overlapping system of mentorship, service, teaching, learning, and authorship that are deeply dependent, social, and human. With a system that is possible of visualizing the history of a digital project over the course of years, which may see the ranks of team members change over time, primary investigators and project funders will be better able to address often thorny and ethically charged issues relating to student assessment, mentorship, authorship, promotion, and tenure. Credit, promotion, funding, and credentialing are more complex topics than ever, yet many individuals and institutions rely on simple, outdated structures to assess the value of insights made by networked teams.

Social Knowledge Creation

The Penn State Digital Humanities Lab (Penn State Behrend) in partnership with the Teaching and Learning with Technology group (Penn State University Park) has developed a prototype of an ongoing project entitled the Social Knowledge Timeline (sktimeline.net). By linking together popular collaboration tools, the SKTimeline stores, analyzes, and communicates user data in three distinct areas of social knowledge creation:

- **Collaboration Platforms:** Many scholars are turning to collaboration platforms like Slack, Yammer, and Basecamp to organize teams and foster communication within teams. These systems use an interface similar to a social media feed to pool project member input into a single narrative and eliminate the need for email. These systems help share documents and support conversations that may lead to drafting manuscripts on Google Drive and other services.

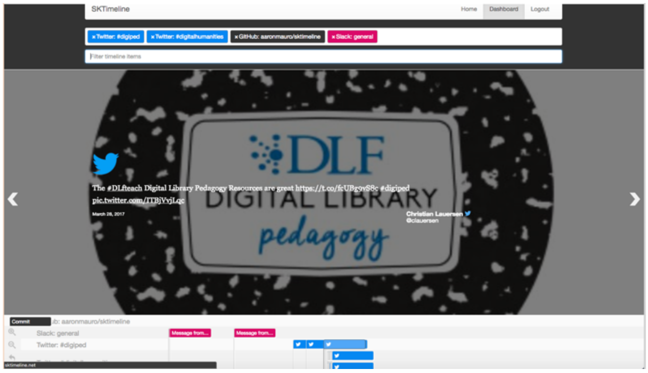
These platforms offer a rich, conversational natural language data set that describes how team members mentor and support each other over time.

- **Version Control Systems:** Github and Bitbucket are two of the most common version control platforms. These tools help facilitate large programming and encoding projects by allowing multiple coders to work simultaneously. When a team member "commits" code, a commit message describes the nature of the contribution as well as the date and time. This message will offer a highly granular view of coding projects as they unfold. Similarly, by including a feed from Google Drive's own version control system, document authorship may be traced with similar precision.
- **Social Media:** Platforms like Twitter, LinkedIn, and Facebook have proven to be fast paced and engaging areas for social and cultural exchange. Twitter has long been a particularly important site for digital humanists. The SKTimeline draws together multiple hashtags and user handles to frame preserve and contextualize this often ephemeral site of both popular and scholarly debate. Hashtags associated with digital projects, conferences, publications, and even course work can be analyzed and set in real time with other platforms.

Credit allocation in large teams is dependent on our ability to describe, quantify, and visualize our activities. By analyzing the rich natural language conversations generated by teams, the SKTimeline solves these ethical and institutional problems. The appearance of "Collaborators' Bill of Rights" for digital humanities projects in 2011 is symptom of a need for greater clarity in heterogeneous collaborative teams (Clement et al 2011). The Modern Language Association's "Guidelines for Evaluating Work in Digital Humanities and Digital Media" are similarly responding to appropriate credit allocation for researchers. There is a need for a more formalized and automated system of data collection and analysis for collaborative researchers across the university.

Machine Learning Contributor Taxonomies

The Taxonomy of Digital Research Activities in the Humanities (TaDiRAH) is used to quantify and describe user contributions. Machine learning systems like Google's Cloud Platform is used to conduct language analysis, and translation, image recognition, sentiment analysis, and keyword extraction. Custom machine learning systems has also been layered on to these services using the Tensor Flow library to learn the project specific phrasing for contributions. Additional text analysis will be conducted using standard tools like the Natural Language Toolkit (NLTK) to link to TaDiRAH's defined contributions. This project will reshape authorship and credit allocation in the humanities and beyond, but it will also be a perfect test bed for an emerging set of artificial intelligence tools that are now finding common application throughout society. In this way, the SKTimeline is representative of a broader cultural trend toward AI systems in aiding research.



The #DLfteach Digital Library Pedagogy Resources are great https://t.co/fcUBg9vS8c #digiped pic.twitter.com/TTBjVvjLqc

March 28, 2017

Christian Lauersen
@clauersen

Figure 1. The Social Knowledge Timeline displaying Slack channels posts and Twitter hashtags chronologically. Images associated with posts are used for backgrounds on the timeline

Conclusion

Undergraduate course projects, ongoing faculty research with graduate researchers, digital humanities labs, and library based digital research projects are just some of the contexts this round of user testing will examine. The data collected on participating teams against interview and form based user surveys. This kind of socially oriented knowledge creation emerges from a community of practice that moves fluidly between curricular experiences and co-curricular research experiences often hosted in DH labs, libraries, and centers. The SKTimeline seeks to solve a critical problem within scholarly communication in a digital context. The SKTimeline offers a means to capture complex narratives that constitute the organic and nuanced unfolding of humanities research.

Research Center as Distant Publisher: Developing Non-Consumptive Compliant Open Data Worksets to Support New Modes of Inquiry

Robert H. McDonald
rhmcdona@indiana.edu
Indiana University, United States of America

Introduction

In the original Google Books Settlement Agreement in 2008 (Courant 2009), funds were to be set aside to create a research center that would enable researchers worldwide to accomplish data-mining and analysis on texts in the public domain and under copyright in a manner that was secure and compliant with appropriate U.S. copyright law. This did not happen, because the court rejected the agreement in 2011. Despite this, in 2011, the HTDL announced that Indiana University Bloomington and the University of Illinois at Urbana-Champaign would run the HTRC under a cooperative funding agreement with the HathiTrust Board of Governors and the University of Michigan. Since 2014, HTRC has made available as an active production service tools to analyze a set of out-of-copyright content equaling around 4.4 million volumes. In 2016, the HTRC plans to enable analysis of the entirety of the 15 million-volume corpus currently held by the HTDL, the largest digital academic library in North America.

HTRC and Non-Consumptive Research

The HTRC has developed a process to define and work within the concept of *non-consumptive* computational access to support the fair-use of the HTDL corpus as defined within the Google Books Settlement Agreement that was a part of the *Authors Guild et al. v. Google Inc* case.

Currently the HTRC defines the process for *non-consumptive* use of the HTDL corpus as:

> Research in which computational analysis is performed on one or more books, but not research in which a researcher reads or displays.

Operationally, from the perspective of the HTRC research cyberinfrastructure, the HTRC defines *non-consumptive* research as:

> That which requires that no action or set of actions on the part of users, either acting alone or in cooperation with other users over the duration of one or multiple sessions can result in sufficient information gathered from a collection of copyrighted works to reassemble pages from the collection.

This concept has been further refined in the course of the development of the HTRC Data Capsule (Zeng et al. 2014) for secure data analysis and the development of the HTRC Workset Ontology (Jett et al. 2016) and has been codified in the recently released HathiTrust Research Center Non-Consumptive Use Research Policy (HTRC, 2016).

HTRC as Publisher

During the course of work with scholars using the HTRC tools and services to create derivative non-consumptive data sets, the Center has often taken on a set of the roles traditionally played by publishers. These data sets are reviewed by members of the HTRC staff for compliance with non-consumptive use standards prior to release to the authors.

As part of this work, the HTRC has offered as a service the capability to publish these non-consumptive, compliant data sets using a DOI scheme (Downie; 2015). This service enables the creation of new derivatives (Downie; 2015) of published non-consumptive compliant data sets.

A second benefit of opening access to these data sets is the ability to replicate current experiments that have been developed using the HTDL corpus and the HTRC tool set. From this standpoint the HTRC functions as a *distant publisher* of non-consumptive compliant data sets in support of new models of research inquiry.

Distant Publishing as Concept

Prior to defining the concept of *distant publishing*, it is first instructive to understand *distant reading* within the context of digital humanities. *Distant reading* was first codified in 2000 by noted humanist and scholar Franco Moretti:

> Distant reading: where distance . . . is a condition of knowledge: it allows you to focus on units that are much smaller or much larger than the text: devices, themes, tropes – or genres and systems. And if, between the very small and the very large, the text itself disappears, well, it is one of those cases when one can justifiably say, less is more. (Moretti 2000)

Moretti later expanded the concept in his 2013 monograph of the same name (Moretti 2013). Much like Moretti's definition that focuses on enabling a broader view of the text, the *distant publisher* enables a broader view of data sets through bringing to bear the current corpus of computational tools for large-scale textual data mining and analysis.

HTRC as a distant publisher is removed by at least one degree from the creator, and remains distinct from any standardized concept of publisher. Yet, data sets are published under the rubric of the HTRC, and these publications are freed from the constraints of copyright in this context due to their non-consumptive nature. Thus we define distant publishing as:

> Publication of a non-consumptive data set outside of any standardized publishing construct, removed by x degree from the original creator, openly available to the community of scholars for replication and available for re-use in support of the advancement of knowledge.

This definition is one that the HTRC aims to further refine in the coming years. We welcome broader thoughts on this concept from those working to preserve open research data and the software that makes that data accessible for use in scientific experimental replication and re-use for the long-term benefit of the scholarly community.

Distant Publishing Use Cases

Currently the HTRC is developing models that support our current definition of *distant publishing*. These models are illustrated in several use cases, outlined below.

- **Extracted Features Worksets** - HTRC expects this concept to be further refined as we move toward the second round of HTRC Advanced Collaborative Support grants which will be funded in summer 2016. Our most progressive case for distant publishing at this point is leveraged through the publication and release of our main extracted features workset. The current workset is a prototype based on the 4.8 million volume public domain collection from the HTDL. Through 2016-17 this workset will be redefined to include more of the HTDL collection. From this initial workset publication we have seen further refinements of the workset by scholars such as Ted Underwood (Underwood et al. 2013), Colin Allen (Murdock, Zeng, and Allen 2016), and Matthew Wilkens (Wilkens 2013).
- **HT+Bookworm** - The HathiTrust+Bookworm (HT+BW) project (2016) presents textual content through interactive visualization. Whereas HT+BW has previously been used in standalone contexts with pre-determined metadata, currently HT+BW is enabling scholars to analyze custom personal collections from within the larger corpus and the use of HT+BW as a supplement to other uses of the HTRC. This concept could eventually become a new possibility for derived workset publication in its own right.
- **HTRC Workset Ontology** - Currently in development, the HTRC Workset Ontology is part of a collections data model by the Workset Creation for Scholarly Analysis project (HTRC 2016), an HTRC research initiative funded by the Andrew W. Mellon Foundation. The resulting HTRC Workset data model is designed to aid humanities scholars by helping them to describe selected portions of the HTDL corpus that serve as the objects of their research. The resulting worksets are persistent, citable, and can be assessed by other scholars for reuse in additional research processes.

Conclusion

Today's digital scholars are embracing new opportunities to explore their disciplines through the type of enhanced computational analysis that the HTRC provides. As the Center works to define emerging possibilities within the context of non-consumptive research, distant publishing will enable us to engage with the community of open data and open software publishers to ensure that our collections are accessible, open and available for the next generation of distant readers and their plans for new forms of scholarship.

Acknowledgment

The author would like to thank the Executive Management Team of the HTRC, J. Stephen Downie Co-Director, Beth A. Plale Co-Director, Beth Naymachchivaya, and John M. Unsworth, and all of the staff of the HathiTrust Research Center and the HathiTrust Digital Library for their contributions to the tools and services that make the concepts in this paper and the research of our users possible.

Online Shadow Libraries and the Future of Humanities Scholarship

Stephen Reid McLaughlin
stephen.mclaughlin@utexas.edu
University of Texas Austin, United States of America

In a publishing landscape long challenged by small audiences, tightening library budgets, and steady growth in the number of monographs produced each year, potentially illegal text sharing has become an everyday practice for many humanities scholars and students, both those with access to conventional distributions channels (libraries, online databases, inter-library loan) as well as independent scholars and those at institutions with limited library resources. Whereas many researchers in medicine and natural science disciplines have embraced open access publication practices, both in open-licensed journals and via centralized preprint repositories, access to scholarship in humanities fields poses greater challenges.

Due to humanities monographs’ limited commercial value, many titles are only commercially available for a short window. As Borgman has noted, “[l]iterature in the humanities goes out of print long before it goes out of date” (2007: 241), while older works from university presses are “virtually entombed” (McGann, 2014: 133) in the stacks of academic libraries. Meanwhile, factors including rising journal prices and an increase in the number of monographs published each year have led libraries to purchase proportionally fewer monographs than in past decades (Thompson, 2005: 103–6). In turn, humanities scholars’ reputation for “unreadable complexity” (Eve, 2014: 22) may be exacerbated by the unavailability of published research. By contrast, informal circulation can provide a double benefit to scholars, allowing them to secure the prestige of publishing with a name-brand university press while reaching a larger audience than would be possible in print alone (Hall 2013). In this paper, I draw on public metadata sets, download logs from Sci-Hub (Bohannon and Elbakyan, 2016), and interviews with operators and users of illicit text sharing sites to examine their place in contemporary humanities scholarship.

A decade ago, illicit text collections, also known as shadow libraries (Liang 2012; Bodó 2015, 2016), were limited in size and existed on the margins of academic culture. Today, one can find millions of books and tens of millions of journal articles spread among Library Genesis, Aaaaarg, and Sci-Hub, as well as in niche collections such as Memory of the World and Monoskop Log. And yet, these sites’ coverage of literary works and literary scholarship is significantly shallower than is the case for published research in medicine, engineering, and the social sciences.

Most shadow libraries are messy, ad hoc affairs, composed of digital objects in a range of formats and quality levels, drawn from a pre-existing ecosystem of interpersonal text sharing among scholars and students. Metadata for the 1.5 million documents in Library Genesis, which is freely available, exhibits what we might call bounded messiness. A tabular dataset riddled with missing values, text encoding quirks, and duplicate entries, it clearly would not pass muster in an academic library setting. However, the simplicity and flexibility of this system make it well-suited for a text collection compiled, maintained, and mirrored by a culturally diverse community of participants. In this case, a just-good-enough database supports the goals of inclusiveness and replication by others.

In interviews with scholars who use shadow libraries, I have observed a wide range of positions with respect to copyright law and the business of scholarly publishing. While some hope for a future in which copyright is abolished and publishers are driven out of business, many are essentially satisfied with the scholarly publishing ecosystem as it stands today. Most use library resources and purchase physical books, turning to shadow libraries to fill the gaps and evaluate texts’ relevance and quality. Nearly all respondents said they prefer to read printed texts when the option is available. Moreover, if the cost of these sites’ continued existence is that they remain culturally marginal, my participants see this as an acceptable tradeoff.

Several interview participants described their personal document management schemes, an age-old form of scholarly labor that typically remains invisible to outsiders. What is new, however, is that some avid collectors are systematically compiling clean copies of their personal libraries, along with extensive metadata and searchable full-text indexes. They then share these collections among colleagues, either on hard drives or in private online repositories. One respondent described this text curation practice as both a pedagogical strategy and an attempt to shape the scholarly canon in his field of study.

There are no easy answers to the problems shadow libraries pose for publishers and university libraries, leading Bodó (2016) to suggest we should "bet on all horses," throwing support behind academic publishers and shadow libraries alike. For now, exploring how where shadow libraries come from, how they are designed, curated, and maintained, and what their futures may hold — including the eventual, inevitable, closure of individual sites — may help us understand current academic culture and possible future models for humanities research and scholarly culture more broadly.

Semantic Domains in Picasso's Poetry

Luis Meneses
ldmm@cs.tamu.edu

Enrique Mallen
mallen.shsu@gmail.com
Sam Houston State University, United States of America

The question of why Pablo Picasso dedicated a considerable amount of his time to writing around 1935 is open to speculation. Many have cited the Spanish artist's emotional crisis, the political turmoil in Europe in the period between the two wars, and the menace of a fratricidal confrontation in Spain as possible causes. All of these views are predicated on an assumed irreducible conflict between visual composition and verbal expression. However, it should be considered that Picasso's interest in alternative methods of expression might have stemmed from his fascination with linguistic structure as a whole during his cubist period. To quote Marie-Laure Bernadac: "I am in complete agreement with [the] linguistics of cubism as a structural language. Picasso is very conscious of the ambivalence of language, the ambivalence of words ... Picasso always played with the ambivalence of words ... The *papiers collés* [may be thought of] as 'proverbs'; that is, as things that take the place of the verb 'to paint' ... The battle between word and image, between art and reality, between different systems of signs ... but one must never forget that Picasso's cubism is two things at once; it's painting and it's language ... His whole life he was obsessed with the relationship between painting and writing ... the battle between word and image, between art and reality" (Rubin et al., 1992). Many other authors have pointed out the parallel development of structural linguistics as delineated by Ferdinand de Saussure and the explorations of the different phases of cubism by Picasso, Braque and Gris.

The connection between his writings and his plastic works has been explored by Cowling (2002), who refers to both his poems and his artworks as executed in a "spider's web" style: "A glance at the manuscripts reveals that he was attentive to the look and lay-out of the pages, relishing the dramatic impact of such things as variations in the size and style of the script, changes in the flow of ink or the thickness of the nib (and the color when he used crayons), contrasts between letters, numbers, dividing lines and the special punctuation marks he favored, different systems for crossing-out and large blots of ink. The calligraphy varies a good deal and is sometimes ornate and the effect handsome and arresting". For a similar position, we may turn to Baldassari

(Picasso and Baldassari, 2005), who poses a clear link between Picasso's visual works and his poetry: "In the decade between 1925 and 1935 ... Picasso continued to pursue cursive linearity in canvases where poetic shapes and ideograms represented bathers and acrobats. The scrolling lines, bursting constellations, curving grids, and broad strokes that cross the surface of his pictorial work then found a new dimension in his poetic writing. Breton fully sensed its importance ... 'This poetry is unfailingly visual in the same way that the painting is poetic'". Earlier, Daix (Daix and Emmet, 1993) had pointed out that "Picasso did not believe in spontaneous poetry – or painting. His attitude was that of a professional: someone who had put written fragments into his paintings and could certainly paint poems as well. The graphism of his letters and the way they were placed on a page were also a deliberate, visual creation". Despite the close correlation between Picasso's poems and his artworks, one cannot deny that Picasso's poetry is essentially verbal, and not conditioned by plastic principles. This is precisely what makes Picasso's poetry so interesting: it provides a window into Picasso's mind that is separate from his own artistic creations.

Our research has taken us through different approaches in order to analyze Picasso's artistic legacy (Meneses et al., 2008a, Meneses et al., 2011) and his poetry. In our study of Picasso's writings, we first created a concordance of all of his poems and plays, separating the poems by language (Spanish and French) (Meneses et al., 2008b). We then designed a dictionary based on this bilingual concordance of poems that was dynamically generated, identifying the stanzas and lines of each poem. A third step led us to provide an English translation to every French and Spanish term, which allowed us to reduce the number of concepts that Picasso works with. This reduction improved clarity for two reasons: First, we eliminated the language distinction (Spanish vs. French); and second, because we merged morphological variation into single units, so that tense/mood alterations for verbs, and gender/number differences for the noun, for instance, were bypassed. As a result, we ended up with three lexical lists: one for Spanish terms, one for French terms, and one with English translations that links the first two lists. The third lexical list may be considered a semantic dictionary specifying concrete concepts in Picasso's writings.

However, we felt that some aspects of Picasso's poetry needed further exploration. In this paper we propose to explore the possibility that Picasso's transition into poetry is simply one more manifestation of his pursuit of alternative approaches to language as a means of representation. In this sense, one thing that remained to be determined was how concrete concepts in both languages cluster into representative semantic categories; and how these categories interact with each other in semantic networks. For this purpose, we have expanded upon our previous efforts by using statistical models and algorithms. More specifically, we have used Latent Dirchlet Allocation: a hierarchical probabilistic generative model that can be used to represent a collection of documents by topics (Blei et al., 2003) to analyze Picasso's poetry. Our analysis demonstrates that topic modeling can highlight patterns and trends in Picasso's poetry that escape other forms of traditional analysis.

We will elaborate on the details of our current analysis using three points. First, it is safe to assume that all poets limit themselves to a number of representational topics as they compose their poems. We know that the European conflict, the crisis in Picasso's own personal relations and the immediate objects in his surroundings constituted the backdrop of many of his compositions. In this respect, topic modeling has allowed us to more precisely delimit the lexical manifestation of these themes, enabling us to see interrelations between words within particular topics.

Secondly, topic modeling has allowed us to see correlations between concrete themes as identified by certain lexical terms and different languages. These correlations are particularly interesting in the case of a bilingual poet like Picasso. For example, psychological concepts–madness, for example– are often handled in French; while more physical references to his immediate surroundings are circumscribed to Spanish terms. However, in cases where both languages are used to communicate a similar concept, Picasso chooses Spanish when he intends to apply a more folkloric tone. Using the English lexical list of terms, we were able to highlight and identify the interconnections between his poems in different languages.

Finally, we have determined that, in Picasso's poems, certain semantic domains are predominant in each of the two languages he used – Spanish and French. For instance, Picasso is more inclined to refer to food items and everyday objects in his Spanish poems, which thus provides a clear reflection of his physical environment and of the harsh economic situation of this time. On the other hand, his French poems concentrate on more abstract concepts involving politics, religion and sexuality, which may be attributed to the influence of French Surrealist writers.

To summarize, in this paper we propose to analyze the ways in which concepts in Picasso's poems and plays cluster into semantic categories; and in turn, how these categories interact with other concepts within a complex semantic network. Furthermore, through the use of statistical models we have been able to identify and pinpoint representative themes and correlations across different languages. Although topic modeling can point us to patterns and interconnections within Picasso's writings, accurately characterizing the nature of these relationships remains a challenge.

Shelf life: Identifying the Abandonment of Online Digital Humanities Projects

Luis Meneses
ldmm@uvic.ca
Texas A&M University, United States of America

Richard Furuta
furuta@cse.tamu.edu
Texas A&M University, United States of America

The Internet, along with the advent of online technologies has provided researchers with greater opportunities to collaborate and create a myriad of digital projects. Taking our research group as an example, we have collaborated in creating online art catalogs (Meneses et al., 2011), interfaces for visualizing and creating poetry (Meneses et al., 2013), and tools for analyzing and exploring Shakespeare's plays (Meneses et al., 2015, Meneses et al., 2016a). However, the convenience and familiarity of computer networks makes us forget (or overlook) that there is a certain fragility associated with our online tools. In turn, this fragility threatens the completeness and the sustainability of our work over time.

Nowadays, a large portion of the research carried out in the digital humanities includes an online project as one of its components. In turn, these digital projects can be catalogued as distributed resources, which implies that the administrative control of information related to a topic may be spread across online resources and/or collections maintained by multiple scholars in different institutions. This administrative decentralization can lead to changes in content that are often unexpected by a researcher.

These unexpected changes can be caused by different factors or circumstances. Changes can occur because of deliberate actions on part of the collector – for example, reorganization of the structure of the collection, switching to a different content management system, or changing jobs and institutions. Changes might also be due to unexpected events – earthquakes, power outages, disk failures, – or may be due to other uncontrollable factors – death, seizure of computers by law enforcement, or termination of the services from an Internet Service Provider (Mccown et al., 2009).

Over time, great strides have been made to harness and manage the fragility of online resources. Klein and Nelson argued that digital documents do not disappear from the Web, but leave artifacts that can be used to reconstruct them (Klein et al., 2011). Bar–Yosseff et al. carried out experiments to measure the decay of the Web (Bar-Yossef et al., 2004). SalahEldeen determined that nearly 11% of shared resources will be lost one year after being published and that this decay will continue at a 0.02% rate per day (Salaheldeen and Nelson, 2012). Nevertheless, and despite these previous efforts, managing and characterizing change in online environments is a complex problem.

Recently, our research group has been focusing on analyzing the perceptions of change in distributed collections (Meneses et al., 2016b). However, we believe that the inherent characteristics of online digital humanities projects present an interesting (and unique) area for inquiry for two reasons. First, the research aspect of digital humanities projects hinders our previous approaches – as our methods for identifying change in the Web do not fully apply. And second, digital humanities projects have a limited useful life – which is accompanied by research from primary investigator, which may or may not be indicated by updates in the project's content and tools. We have seen many cases of successful projects in digital humanities (that fulfill their original objectives and achieve their expected level functionality) that interestingly become abandoned at some point in time. Examples of abandoned successful projects include the Cervantes Project and the TAMU Herbaria Project. This abandonment might be caused by a different set of reasons –which are not often apparent to its users– such as loss of funding, change in personnel or simply decay in interest. We believe that all these reasons are worthy of study.

All this reasoning led us to formulate the following question: When can online digital humanities projects be considered abandoned? In this paper, we propose to present a study on the persistence and average lifespan of online projects in the digital humanities. More specifically, we will elaborate on their reliance on distributed resources and methods for measuring their shelf life: the average length of time that a digital project can endure without updates until it can ultimately be considered abandoned by its researcher.

Furthermore, we believe that "abandonment" is not necessarily a sufficient designation —as there are different nuances involved. We will proceed to elaborate on them using one of our online projects as an example. Digital

Acting Parts is an online project that encourages active reading and memorization, which in turn leads to a better understanding of Shakespeare's plays. The project has been active since 2013, but online development has shifted to a set of different processes that are carried out behind the scenes. Consequently, the project's online presence has not been updated for some time now (we estimate that it has been at least a year). However, the online tools are quite stable at this point. In this specific case, the lack of updates and new content is not a signal of abandonment. This is clear example of why the rules for traditional websites do not fully apply and new metrics are needed to identify issues concerning online projects in the digital humanities.

Our study is an attempt to categorize change in a very specific domain. As an attempt of categorization, determining the degree of abandonment affecting a digital project over time is a difficult task. A Web resource may gradually degrade from being correct to one that is still of some use by providing access to related information or information about the institution to contact for more information. Abandonment can also be hinted by changes in Web servers, directory structures, etc., which may cause Web requests to still result in a successful responses from a server, yet provide no valid information to the requestor. Based on our findings, we approximate the average shelf life to 5 years, which aligns with reports from previous work (Goh and Ng, 2007).

Additionally, our study will touch upon on potential strategies for the archival and the long-term preservation of abandoned digital online projects. It is important to highlight that different levels of preservation and curation are needed among digital projects. Historically, preservation efforts have been primarily concerned with maintaining the primary artifacts in collections; relegating descriptive metadata to a lesser level of importance. There is an underlying notion that descriptive metadata is static: requiring minimal resources to maintain and consequently making it easier to preserve. However, our previous work (Meneses et al., 2016b) has shown us that this is not the always the case.

To summarize, in this paper we propose to identify indicators of the abandonment of digital humanities projects – as well as identifying their average lifespan. Digital online projects in the humanities have unique characteristics that make them impervious to the metrics that used in the Web as a whole. In our opinion, these unique characteristics make them worthy of study. In the end, the purpose of our study is to gain a better understanding of digital humanities projects, their lifespan and formulate better strategies for their long-term preservation.

Decolonizing Knowledge Structures in Open Access and Scholarly Publishing

Nirmala Menon
nmenon@iiti.ac.in
Indian Institute of Technology, India

One of the agenda questions for the Internet Researchers Conference (IRC) 2017 scheduled to be held at IIIT, Bengaluru India is: "What research tools and infrastructures are needed to study, document, annotate, analyze, archive, cite, and work with (in general) digital objects, especially those in Indic languages?" However, before we get to this core question in the research arena we need to confront the fundamental gap in the conversation– that there are as yet very few digital objects that are created, developed and preserved in Indian languages. Shodhganga, a digital repository for dissertations and theses from universities in India, is a national digitization project that has now grown substantially as a scholarly resource. Similarly, we have the National Digital Library, a project that plans to make curricular access electronic. However, both extraordinary projects are still limited to works that are primarily written in English. This is especially unfortunate in literature research. Literature departments across universities in India have a robust scholarship agenda and have some niche publications that focus on the works of literatures of the different languages as recognized in the 8th schedule of the constitution of India. What is missing is a bridge or a platform that enables a conversation between the scholarships in these languages. Certain university department structures– those lacking a department of Literature hospitable to comparatist conversations– have to take some responsibility for this lack of conversation. There are complicated economic and social factors beyond the scope of this discussion that are at play in this disproportionate representation of Indian literatures. It suffices to say, we need specific digital tools that recognize and fill this gap.

At the Open Access Scholarly Publishing project at IIT Indore, we have tried to identify and fulfil what we see as two scholarly imperatives: 1) a commitment to open access environment as crucial for research accessibility and 2) providing a platform for multilingual scholarly production with an emphasis on Indian languages. The Digital Humanities and Publishing Research Group at IIT Indore has a two-pronged approach to what we see as a fundamental infrastructure problem: the absence of a polyphonic platform for a scholarly kitchen! The publishing project KSHIP was born from deliberation over these crucial issues challenging scholarship publishing in India.

KSHIP or Knowledge Sharing in Publishing recognizes this gap and advocates a philosophy of open access as crucial to a cooperative global knowledge production network. In its initial pilot/launch phase, KSHIP includes 1) a project of database development of scholarship and criticism in Indian languages. (we are starting with three languages, with the eventual goal of making KSHIP a crowd sourced platform with more languages to be added soon), and 2) we will be a consciously multilingual publishing house soliciting (and specifically targeting) scholarly monographs and translations in Indian languages, while also inviting scholars to host journals in multiple languages. In this session we would like to discuss some of the technological challenges of the project and possible solutions with an emphasis on collaborations across institutions and scholars in India.

The database development project addresses the first issue of dissemination and access to scholarship in regional language literatures in India. We have started a pilot with four languages with citation data from three different languages being uploaded. This will truly be a crowd sourced project in the future and we are in discussion with journals/publishers about uploading data to the platform. At least in the beginning, this platform will also be a part of KSHIP. We are looking for scholars from different languages to contribute to and be a part of this project. The project will be collaborative in the largest sense of the term.

The project also includes a prototype of a translation plug-in tool. This is a crowd-sourcing translation tool developed as part of an UG project and directed by myself and my colleague from Computer Science, Dr Abhishek Srivastava. We hope to finesse the initial prototype of the tool over the coming months (and may even have a final prototype ready by the conference in Montreal!). The translation tool is designed to slice a scholarly paper/article so that one paper can potentially be translated by more than one person, and then moderated and collated at the publisher’s end. There are several challenges posed by such a crowd sourced model. These include, among others, issues of author/translator attribution, for which we are currently discussing and thrashing out different options. The interface will also offer the option of solicited translation, especially in the case of literature scholarship. We will experiment with the crowd-sourced translation using scientific and engineering essays.

In this short paper I will discuss: 1) The infrastructure gap in scholarly publishing in India, 2) the need for this to be addressed with a focus on multilingual publishing, and 3) the technological challenges specific to an ambitious long-term project. These questions will inevitably lead to discussions on digital preservation and the transforming and transformative role of technology in that process.

ELLE the EndLess LEarner: Exploring second language acquisition through an endless runner–style video game

Games have been used to help people learn throughout history (Vankúš, 2005). Video games are interactive and encourage active learning (Domínguez, Saenz-de-Navarrete, de-Marcos, Fernández-Sanz, Pagés, & Martínez-Herráiz, 2013; Watson, Mong, & Harris, 2011) more so than learning via lecture or textbook reading. The interactive nature of games also makes them engaging to the player. Student engagement is an essential component of learning (Fredricks, Blumenfeld, & Paris 2004; Hall, Ramsay, & Raven, 2004; Kahu, 2013). Most scholars agree that games, when designed well, can increase student learning and retention (Ricci, Salas, & Cannon-Bowers, 2009) as well as motivation (Gee, 2003; Fullerton, 2014; Eichenbaum, Bavelier, & Green, 2014).

Sykes and Reinhardt (2013) define game-based second language learning and teaching as the "use of games and game-inclusive synthetic immersive environments" (p. 5) that are designed specifically for second language learning contexts. They also state that few game-based spaces are available specifically for second language learning purposes. Scholars have noted the unintentional effect on second language learning that commercial games can have, for example, children in countries where English is not commonly spoken have been observed as acquiring knowledge of the language as a means to play the game (Sørensen & Meyer, 2007). Other research has focused on second language-learning interactions that learners form in multi-player video environments, including those associated with video game chat rooms (Ryu, 2013). Although some video games that target language learning have emerged, such as *Croquelandia, Language Island, Mentira, MIDDWorld Online,* and *Zon* (Sykes & Reinhardt, 2013), much research remains to be done in the efficacy of this game genre. The central question guiding our research is: How can a videogame best be designed to effectively enhance student second language acquisition?

To answer this question, we turn to Ellis's (1985) recommendations to facilitate language learning: the quantity of input directed at the learner, the learner's perceived need to communicate in the second language, and the here-and-now principles. Current second language pedagogy also stresses that learning should be authentic and goal-oriented. Drawing on socio-cultural theory, researchers have linked second language acquisition with a "language game" (Lantolf, 1997), explaining that play can allow learners to rehearse linguistic forms they already know and to experiment with new input in a low-pressure environment. The game we are developing will satisfy Ellis's requirements for the quantity of input, the necessity for competency in the language (to advance in the game), and the "here-and-now" principle, in addition to authenticity and goal-orientation.

This session will explain and demonstrate *ELLE the EndLess LEarner*, a game prototype designed to enable the study of secondary-language acquisition through an endless runner game platform. The system is designed so that different game features, specifically auditory, visual, and textual cues, can be modified easily by a researcher and the efficacy of each studied in relation to language acquisition and the game platform. The platform has been designed in this way to allow for research into the impact of these different cues and input methods on the activities being studied.

The style of *ELLE* is an "endless runner," which means that the player's avatar is continuously in motion, "running" through the game environment. For example, the iOS game *Temple Run 2*, continuously moves the player forward, without allowing the avatar to stop. The only controls available to the player are turning right or left, and jumping over or ducking under obstacles. The player cannot control the speed of motion though it can be manipulated through in-game objects. This game style results in a fast pace requiring players to react rapidly, and it has great potential to increase student motivation and engagement in the types of common sense practice exercises that help solidify vocabulary acquisition. *ELLE* is being designed in conjunction with modern language researchers and is grounded in the scholarship of language learning theories and evidence-based pedagogical methods.

We chose an endless runner style videogame to address a number of practical concerns, as scholars assert that the connection between game mechanics and intended argument must be intentional (Bogost, 2007). First, this popular style of game is intuitive and easy to play. Next, we believe the endless runner style, being a casual game, will be less intimidating for learners who do not identify as "gamers." The fast pace of this style requires rapid recall and provides immediate feedback in a low-consequence environment that lends itself to repeated play and therefore repeated reinforcement of the content. Endless runner games limit player choices within the game, which allow for an increased emphasis on the language terms being practiced. Finally, this prototype, initially focusing on vocabulary acquisition, lays the groundwork for future iterations of the game as an on-demand language practice tool that will have the ability for instructor modification of content.

We have chosen Portuguese as the initial language for *ELLE* to teach, as it is one of the most important world languages today. As the sixth most spoken language in the world, the Portuguese language is a gateway to the cultural and economic opportunities of Brazil and the rest of the Portuguese-speaking world. From Portugal to the emerging economies of Africa, the Portuguese language has over 200 million native speakers, is an official language in nine countries, and is spoken on three continents. The US government considers Portuguese to be a language of "critical need," especially because of the nation's trade relations with Brazil.

ELLE is being designed as a game system that can continue to be studied and built upon over time. The team's initial goal is for *ELLE* to function as the center of a variety of studies to increase understanding of second language acquisition. *ELLE* is being designed using the *Unreal Engine* and readily available tools and tutorials, to reduce costs and to allow for increased focus on the variety of cue types that are of interest to the research team. This game prototype style, with its manipulable components, will allow the team to quantify the effects of different game features and player actions. Additionally, the components can be used to increase accessibility and to adapt the game based on player needs. This empirical data can then be leveraged and further explored to increase the efficacy of language learning games.

Our research will work to identify what motivates and engages SLA learners, relying on self-determination theory (Ryan, Rigby, & Przybylski, 2006) to ensure an appropriate balance of intrinsic and extrinsic motivational strategies. The design team's collaboration with modern language instructors has identified a lack of postsecondary level SLA supplemental tools that students find motivating; therefore, this prototype has the potential to inform improvements to future tools for second language instruction. This game is intended to act as a supplement to instruction and other classroom activities, rather than a replacement. Because student motivation is such a major factor in learning, the learning research undertaken as part of this project will also examine student engagement using the model of mastery and performance goal orientation (De Clercq, Galand, and Frenay, 2014). Mastery of second language concepts will motivate some students while others may focus on their performance against their peers. In addition to testing the game feature of textual, visual, and auditory cues, the team is also investigating the impact of game mechanics such as leader boards on student motivation.

The team's long-term goal is to create a robust database-driven game that can be easily customized to teach vocabulary words / phrases / pictograms from any semiotic domain, regardless of language or subject, particularly at the primary and secondary school levels. *ELLE* will be leveraged to research socio-cognitive variables of domain language acquisition. Such socio-cognitive variables include questions about how the gaming environment influences learners' motivation and how the interaction within the multimodal space of a video game could be affected by different aspects of identity, for example, gender. Potential semiotic domains could even include STEM subjects such as chemistry and biology. In other words, the proposed project will allow the investigative team not only to develop an effective game through which to introduce a second or additional language but, ultimately, to allow the team to explore both cognitive and social aspects of language acquisition.

An Automated Approach to Model the Transformation Process of the Reuse in Bernard de Clairvaux: How Do Lexical Resources Help?

Maria Moritz

University of Goettingen, Germany

Marco Büchler
mbuechler@etrap.eu
University of Goettingen, Germany

Abstract

To fortify the research of automated, historical text reuse detection, it is necessary to investigate the way in which a text is reused (e.g., verbatim, paraphrased) in order to understand the broader context of a reuse. Our long-term goal is to build a formal theory behind reuse transformations. We have previously investigated two datasets of Bible reuse to analyze how reuse is modified and how linguistic resources support this. In this work, we investigate the ratio of non-literal text reuse, and we measure to which extent the Ancient Greek WordNet—which also contains Latin WordNet—and BabelNet can support identifying lexical relations in Latin reuse excerpts. In doing so, we also show the lack and need of resources for ancient data.

Introduction

The automated detection of historical text reuse is still in its early stages. To reinforce its research, it is necessary to investigate the way a text is reused in order to understand the broader context. Here is where the necessity of lexical resources supporting this task comes in, especially when a text is non-literally reused, and words are substituted with semantic equivalents, such as synonyms or other semantically similar words. Our long-term goal is to formally model reuse transformations. The analysis of the amount and type of substitutions of words with lexically related words enables insights into how text is reused. Applying these insights into future development of detection methods helps to improve them. We have previously investigated two datasets of Bible reuse, trying to understand how reuse is modified (when operations are performed on word pairs) and how linguistic resources support this task. To achieve this, we need to study more and different cases of reuse. In this short paper, we propose and report on work that extends the number of reuse excerpts we investigated in previous work (Moritz et al., 2016), and take another linguistic resource, BabelNet into account. We aim at investigating the current state of lexical resources' support for a Latin reuse dataset. We compare the support we can get from an additional lexical resource to previous results. Specifically, we investigate BabelNet (BN) (Navigli and Ponzetto, 2012), a multiple resource network pulling from different sources, and we compare the reuse detection support (how many words are covered) between BN and Ancient Greek WordNet (AGWN) (Bizzoni et al., 2014), which also contains Latin WordNet (Minozzi, 2009). Both are recently developed resources and the most common for the Latin language. BabelNet is produced from a range of different, contemporary sources, such as Wikipedia and Wikidata. We are interested in the extent to which BabelNet is able to cover words and relations from an ancient reuse dataset. We are especially curious about what words are still supported by current resources. Our ultimate goal is to simulate a transformation process that also supports non-literal reuse. This can help to model the changes that were applied to an ancient text during its reuse history.

Background

The field of automatically detecting historical text reuse is still in its early stages. To date, Büchler (2013) combines state-of-the-art NLP techniques to address reuse detection scenarios for historical texts, ranging from near copies to text excerpts with a minimal overlap, using a method, which selects n-grams from an upfront pre-segmented corpus. While the approach can discover historical and modern text reuse language-independently, it requires a minimal text similarity. Recognizing modified reuse is difficult in general. Alzahrani et al. (2012) study plagiarism detection techniques, such as n-gram-, syntax-, and semantics-based approaches. However, as soon as reused text is modified (e.g., word substitution), most systems fail. Finally, lexical resources support the identification of relationships between words, but they are not free from issues (Jing, 1998) that can appear when they are used to adapt a general lexicon to a specific domain (Miller et al., 1990).

Data

Our dataset contains excerpts from twelve works—mainly sermons and treaties (Literature)—and two work collections—sermons and letters—from the Latin writer Bernard of Clairvaux (c.f., Moritz et al., 2016). All those texts come from the *Sources Chrétiennes* collection (c.f., Mellerin, 2014) (changes in format and orthography may be inserted by the editor). The Biblindex project (Mellerin, 2014) extracted over thousand Bible reuse exerpts from these works, each of which points to a Bible verse. We use the Latin Bible from Biblindex, called *Biblia sacra juxta vulgatam versionem* (Weber R., 1969) to link the excerpts to the respective Bible verses. We come up with 1,128 unique reuse-to-bible-verse pairs. Table 1 shows one example.

	Bible verse	Bernard reuse
Proverbs 18 3	impius cum in profundum venerit peccatorum contemnit sed sequitur eum ignominia et obprobrium	Impius , cum venerit in profundum malorum , contemnit
English	The wicked man, when he has come into the depth of sins, despises: but ignominy and reproach follow him.	The wicked man, when he has come into the depth of evils, despises

Table 1: Example of reuse

Methodology

We use AGWN, which is automatically constructed from Greek-English digitized lexicons, which again were provided by the Perseus Project (Crane, 1985) and also aligns to Minozzis Latin WordNet (Minozzi, 2009). BabelNet (Navigli and Ponzetto, 2012) is a multilingual semantic network that integrates lexicographic and encyclopedic knowledge from WordNet (Fellbaum, 1998), Wikipedia, and others. We further use lemma lists from the Biblindex project, as well as the Latin lemma list from the Classical Language Toolkit (CLTK), which is available in the online GitHub repository of the CLTK (Johnson et al., 2014 2016), to increase the hit rate when querying both resources.

To model the transformation in-between two text excerpts, we define replacement operations (OPs) (see Table 2) that represent the transformation of a reuse to the Bible verse it refers to, as well as an algorithm that identifies those operations between word pairs of a reuse and a Bible verse in a prioritized order. Our algorithm first finds all possible operations for a reuse word, and then applies the most literal operation using the counterpart Bible verse word, which fulfills this operation. This means that if no perfectly or lemmatized matching word is found, relationships of semantic closeness (such as synonyms) for a given word are retrieved. We call the group of semantic operations non-literal operations (c.f., Table 3). We apply our algorithm (which identifies the operations) on Bernard's reuse, first using the relationships queried from AGWN and second, using BabelNet. Afterwards, we show which operations are identified, and calculate a support value for both processes.

operation	description	example
NOP(reuse_word, orig_word)	Original and reuse word are equal.	*NOP(maledictus,maledictus)*
upper(reuse_word, orig_word)	Word is lowercase in reuse and uppercase in original.	*upper(filio,Filio)*
lower(reuse_word, orig_word)	Word is uppercase in reuse and lowercase in original.	*lower(Gloriam, gloriam)*
lem(reuse_word, orig_word)	Lemmatization leads to equality of reuse and original.	*lem(penetrat, penetrabit)*
repl_syn(reuse_word, orig_word)	Reuse word replaced with a synonym to match original word.	*repl_syn(magnificavit, glorificavit)*
repl_hyper(reuse_word, orig_word)	Word in bible verse is a hyperonym of the reused word.	*hyper(cupit, habens)*
repl_hypo(reuse_word, orig_word)	Word in bible verse is a hyponym of the reused word.	*hypo(dederit, tollet)*
repl_co-hypo(reuse_word, orig_word)	Reused word and original have the same hyperonym.	*repl_co-hypo(magnificavit, fecit)*
lemma_missing(reuse_word, orig_word)	Lemma unknown for reuse or original word.	*lemma_missing(tentari, inlectus)*
no_rel_found(reuse_word, orig_word)	Relation for reuse or original word not found in word net.	*no_rel_found(gloria, arguitur)*

Table 2: List of operations and corresponding examples (cf. Moritz et al., 2016)

Results

Table 3 shows the identified operations. Using AGWN, we encounter a high ratio of synonyms (repl_syn), a lot of co-hyponyms and a significant number of hyperonyms and hyponyms. With BabelNet these figures are about a tenth as high. Table 3 shows that the values for **NOP**, **lower** and **lem** (matching words, and words with same lemma) slightly differ in-between both word nets. This is caused by a design decision of our algorithm, which pragmatically permits to reassign a word when it already was used in an association with an earlier word.

	literal				non-literal				unclassified		
	NOP	upper	lower	lem	repl_syn	repl_hyper	repl_hypo	repl_co-hypo	no_rel_found	lem_missing	total
AGWN	4521	1	396	770	397	125	124	316	2470	450	9570
BN	4524	1	397	771	25	21	36	112	3233	450	9570

Table 3: Absolute numbers of operations identified

Fig. 1 shows that AGWN outperforms BabelNet in identifying semantic relations, which represent non-literal text reuse, because these ratios are much lower for BabelNet than for AGWN. We further encounter three significant descents: between 0% and 10%, 30% and 40%, and 50% and 60%. Looking into samples deeply, we find three patterns: i) the more semantic related words are replaced in a reuse, the more likely it is an allusion or analogy, and the less paraphrased or verbatim it is; ii) short allusions are better covered by the Latin synsets than paraphrases with a high ratio of semantic related words; iii) paraphrases with a high literal ratio are covered best. We summarize that both word nets cover paraphrased reuse to a certain extent of replaced words, and AGWN better identifies allusions.

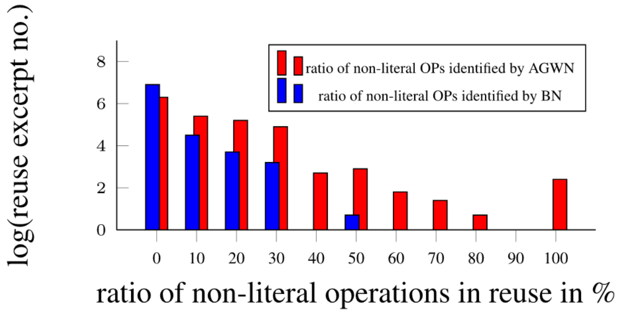

Figure 1: Ratio of non-literal (semantic) operations, aggregated in 10%-steps in relation to the whole reuse length. The reuse number is displayed logarithmically due to clarity reasons.

Lastly, we calculate a support value, which determines the ratio of non-literal operations (c.f., Table 3) compared to them including unsuccessful resource look-ups (no_rel_found) in both, AGWN and BN. For AGWN this value is about 28%, for BabelNet about 6%. Both values are to be understood as lower bounds, because often there is no reasonable relationship in-between two words.

Even if BN coverage is poor, its results tell us, which words of a dataset of medieval, Biblical Latin and Latin of the church fathers are prevailed in a current resource. Some examples are words such as **gloria** (glory) (contained in 17 synsets), **corona** (crown) (contained in 10 synsets), or **nemo** (nobody) (contained in 4 synsets).

Conclusion

We identified the ratio of non-literal reuse in a Latin dataset and showed the support of two lexical resources. Our results show that language resources for Latin reuse are limited and that only a small part of the required coverage is supported. This result raises awareness for the lack of resources for ancient data, despite the growth of language resources for modern languages. Our future work includes refining our operation set, analyzing more languages, increasing the size of our datasets, and investigating probability measures for those data in lexical hierarchies. Since lexical resources will never completely cover the vocabulary at hand, we further consider the application of a form of word embedding.

Acknowledgements

We thank Laurence Mellerin for providing the dataset we used, and for advice on its content. Our work is funded by the German Federal Ministry of Education and Research (grant 01UG1509).

Abstract

The research group on four-dimensional research and communication of urban history (HistStadt4D) aims to investigate and develop methods and technologies to transfer extensive repositories of historical media and their contextual information into a three-dimensional spatial model, with an additional temporal component. This will make content accessible to different target groups, researchers and the public, via a 4D browser. A location-dependent augmented-reality representation can be used as an information base, research tool, and to communicate historical knowledge. The data resources available for this research include extensive holdings of historical photographs of Dresden, which have documented the city over the decades, and digitized map collections on the Deutsche Fotothek (German photographic collection) platform. These will lay the foundation for a prototype model which will give users a virtual experience of historic parts of Dresden.

Introduction

Imagine you're exploring the historic center of a city with its impressive town houses, churches and monuments. What if you could just use your mobile to find out about the historic buildings around you, with detailed visual information about how they were built and the story behind them, mak-ing history come alive before your eyes?

Photographs and plans are an essential source for historical research (Burke, 2003, Paul, 2006, Wohlfeil, 1986, Pérez-Gómez and Pelletier, 1997) and key ob-jects in eHumanities (Kwastek, 2014). Numerous digital image archives, containing vast numbers of photographs, have been set up in the context of digitization projects. These extensive repositories of image media are still difficult to search. It is not easy to identify sources relevant for research, analyze and contextualize them, or compare them with the historical original. The eHumanities research group HistStadt4D, funded by the German Fed-eral Ministry of Education and Research (BMBF) until July 2020, is investigating and developing methods and technologies for this. The junior research group consists of 14 people – including 4 post-doctoral and 4 PhD researchers. Since a focal interest is to comprehensively investigate how to enhance accessibility of large scale image repositories, researchers and research approaches originate from the humanities, geo- and information technologies as well as from educational and information studies. In contrast to adjacent projects dealing primarily with large scale linked text data as the Venice Time Machine project (2017), sources addressed by the junior group are primarily historical photographs and plans. Historical media and their con-textual information are being transferred into a 4D – 3D spatial and temporal scaled - model to support research and education on urban history. Content will be made accessible in two ways; via a 4D browser and a location-dependent augmented-reality representation. The prototype database consists of about 200,000 digitized historical photographs and plans of Dresden from the Deutsche Fotothek (German photographic collection).

Key Aspects

Usage scenarios and research values

Digital image repositories meet a wide range of needs, from research in humanities and information technologies, through museum contexts and library studies to tourist applications (Münster, 2011). Architectural historians have developed various methods of analyzing both preserved and never-built or destroyed structures in chronology and context (Brassat and Kohle, 2003). Style analysis, iconographic approaches, and art sociological methods all address structural historical questions. The technological possibilities of digital image repositories allow architecture historians to draw on a much larger stock of material, and to process and evaluate this from new perspectives. In addition, innovative software tools can be used to locate sources temporally and spatially, or to support dating, stylistic criticism, authorizations or archaeological investigations (Verstegen, 2007). Depending on the user group, a number of contradictory requirements must be met. Historical researchers, for example, need to be able to compare and contextualize sources (Münster et al., 2015, Brandt, 2012, Wohlfeil, 1986), and to trace the relationship between source and representation (Favro, 2006, Niccolucci and Hermon, 2006). This includes identifying formal patterns, singularities, and discontinuities in architecture and cityscape. This raises a host of questions: How do buildings and cities change over time? In which contexts, such as political or formal developments, does a historical cityscape evolve? What similarities can be found between objects in terms of construction standards and requirements, building codes, regional, temporal or personal tastes and styles?

The research group will address these and many more questions in a specific project on the interdependence between urban development and urban photography.

Creating targeted tools for working with image repositories

An adjacent task will be to perform a systematic survey of the needs of users of image repositories, whose findings will be used to conceptualize technological support options. As historic images, objects and information are increasingly being digitized on a massive scale, more content becomes available for investigation; more cross-analyses are possible; more knowledge is collected, structured and shared (Schuller, 2009). The new scale of research and information retrieval creates many new challenges. Many scholars note that online searching for images and information is "counter-productive" due to the amount of irrelevant data retrieved or their limited technical abilities (Beaudoin and Brady, 2011). Access and efficient data retrieval is inhibited for a variety of reasons. The degree of search expertise is as important as the functionalities and usability of the platform (Kemman et al., 2014). A lot of the existing tools of research programs and applications stem from computer science and do not necessarily meet the needs of humanities scholars (Dudek et al., 2015). Users need efficient search and filter functions, an intuitive software interface and navigation system (Barreau et al., 2014). Appropriate documentation through metadata plays an important role in ensuring sustainability (Bentkowska-Kafel et al., 2012, Maina and Suleman, 2015). In contrast, users expect an intuitive and feasible introduction to the topic and data (Maina and Suleman, 2015) with options to find out more as required. The simplest way to link and contextualize visual information is to use highlighted keywords as hyperlinks in texts and captions. Data interaction and processing tools are also essential for research (Webb and O'Carroll, 2013, Hecht et al., 2015).

Photogrammetric methods of visual knowledge generation

A possible technological basis for creating access to large scale image repositories is the spatial and temporal aggregation of data, in this case historical photographs in a 4D model. The potential of photographic images ranges from pure documentation in archaeology and monument preservation, through image interpretation, for example for damage documentation, to the production of complex 3D models for archaeological investigations (Bührer et al., 2001). Geometrical reconstruction from historical photographs is based on photogrammetry. Information from multiple 2D images is used to acquire 2D and 3D object geometries and have frequently been applied on historical and measurement images (cf. Wiedemann et al., 2000, Bräuer-Burchardt and Voss, 2001, Henze et al., 2009, Siedler et al., 2011). Since some decades, traditional analytical photogrammetry has increasingly been complemented by digital image processing and analysis. The elaborate process of manual image analysis can be largely automated, resulting in large image collections from which geometric information can be generated automatically (Pomaska, 2011). To date, automated photogrammetric methods are generally used primarily to evaluate current, mostly digital images. So far, this has rarely been done for historical images, as it involves specific challenges. Scanned analogue records usually have unknown camera metrics, missing or minimal object information and low radiometric and geometric resolution. Our aim is to develop application-oriented tools for photogrammetric analysis of historical photographs, to integrate them into the process of historical image analysis (Fig 1), and to create a spatial relationship to today's situation.

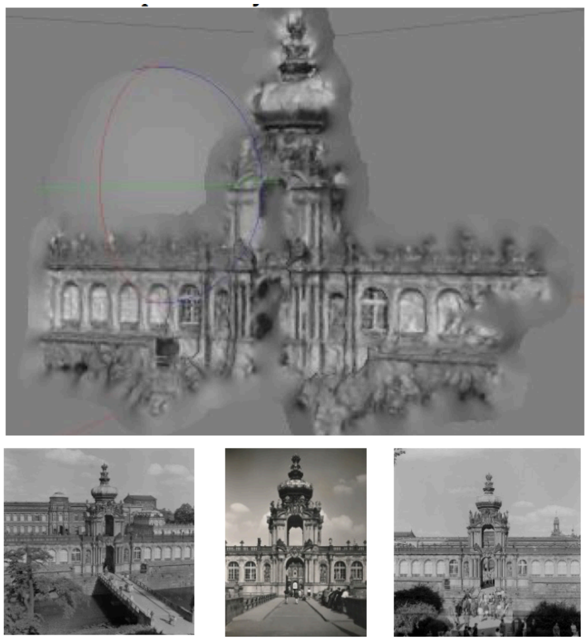

Figure 1. 3D model based on current photographs and historical photographs (proof-of-concept)

Augmented reality

The prototype 4D model, and the 4D historical photographs, drawings, plans, and information within it, will be made accessible via a location or context related information access as augmented reality (Münster and Niebling, 2016). This technology has gained importance in the last few years and undergone extensive testing (Livingston et al., 2008, Zöllner et al., 2010, Walczak et al., 2011, Chang et al., 2015, Chung et al., 2015). Augmented reality describes the enrichment of the real world through virtual data, which can include 3D models, texts, pictures, films or audio data.

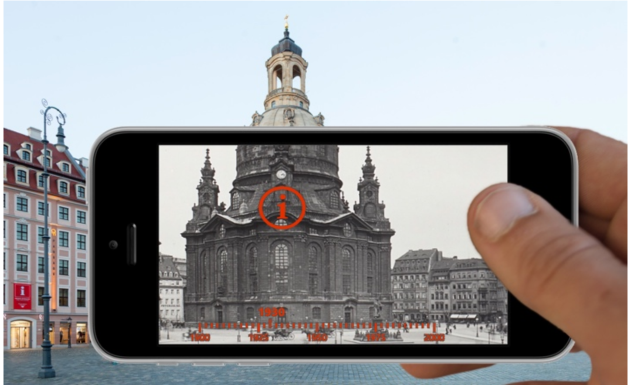

Figure 2. Augmented-reality representation of a cityscape (mockup)

Enriching the reality or replacing parts of reality can help to bridge the cognitive gap between our daily life experience of a cityscape and its depiction in historical photographs (Niebling et al., 2008). In the historical context, the viewer is able to interactively capture visual and textual information about objects in their historical spatial reference system (Ridel et al., 2014). Our investigation will focus on the accessibility of historical data: How can interaction with virtual buildings be designed? Which metaphors can be used? How can augmented reality support educational and research settings?

Figure 3. 4D-Browser (prototype)

As an alternative path, the 4D model will also be accessible via a 4D browser interface for spatially and temporally located searches in media repositories. An basing application prototype of a research platform for 3D reconstruction projects is in development was developed during a master thesis (Bruschke, 2015), employing approaches, such as semantic data linking and visualization of temporally and spatially arranged information (Gouveia et al., 2015). Since the prototype has focused on individual building complexes, the 4D browser application has to visualize an entire city model, which also changes constantly over time. Moreover, a visual interface is proposed to make additional information accessible, such as the current and original location of the depicted object. Further features intended to support scholarly users of the prospected platform are image rectification tools and overlays combining several pictures from different periods which can shed light on changes in a building. Statistical analyses of photographed objects over time may provide information on a building's significance. Last but not least, the application should be intuitive to operate for a heterogeneous user group (Warwick, 2012).

Summary

As a result of huge and concerted digitization efforts, extensive digital repositories of historical photographs have been created in the past few decades. This volume of data presents a major challenge to support search, access and information enrichment for users. In August 2016, the HistStadt4D research group started examining scientific methodological requirements and intuitive user interfaces for dealing with massive media repositories from a multi-disciplinary perspective.

Digital Analysis of the Literary Reception of J.W. von Goethe's *Die Leiden des jungen Werthers*

Introduction

The impact of Johann Wolfgang von Goethe's epistolary novel *Die Leiden des jungen Werthers* marks a singular moment in German literary history, as it sparked a remarkable critical and productive literary reception. After the publication in 1774, so-called *Wertheriaden* — literary adaptations that are formally, thematically and structurally guided by Goethe's novel — appeared in various languages. These texts form our corpus for the Werther Project, which is part of the interdisciplinary DH Project CRETA of the University of Stuttgart.

Literary studies have mainly concentrated on individual texts of this literary reception and on the individual genres to which the adaptations belong. Our research approaches focus on a macro-perspective to recognize recurring structures, elements, motifs and character constellations in all of the *Wertheriaden* with the help of computer-assisted analysis. From this perspective, we want to determine how closely the literary adaptations are based on Goethe's original text *Werther.*

Corpus

Our Werther corpus contains about 150 German and 30 English texts from different genres and literary periods — mainly (epistolary) novels, dramas and poems. The rationale for our corpus selection is based on *Werther's* publication in 1774 and its translation into French (1776) and English (1779). In the last two decades of the 18th century no other work of German literature was ever been translated or adapted in English as often as Goethe's novel.

To establish comparative parameters for such a heterogeneous corpus (which also allow an analysis across all literary genres), we concentrate on specific features which are present in Goethe's original work. Among these discernible and typical characteristics (Martens 1985) are the triangular relationship of the three main characters, the concept of the "Werther character" (emotional, artistic), the monoperspectival narration, the role of nature (with motifs such as "Herbst", i.e. autumn), the subject's relation to society, the so-called "sickness unto death" ("Krankheit zum Tode") with the protagonist's subsequent suicide, as well as structural, stylistic and linguistic similarities (Horré 1997). These reference points will be applied leading to a large scale comparison.

One approach is to compare the different texts on the basis of network and lexical information. In this context, we are concentrating on the visualization of the typical character network of Goethe's original text and whether this triangular constellation reoccurs in the *Wertheriaden.*

Character Networks

The analysis of character constellations is an essential part of literary studies. It shows the dynamic structure of the interactions of the central characters in the text and characterizes them in relation and contrast to each other (Pfister 1982). In the last few years, there has been a growing interest in graph-theoretic visualization and analysis of social networks in literary texts — especially in dramatic texts (Hettinger et al., 2015, Trilcke 2013, Moretti 2011).

Central character constellations occur in all literary genres and form the basis for conflict constellations, particularly for the static counter-narrative between a protagonist and an antagonist. In Goethe's *Werther*, this typical constellation is extended by another figure — Lotte. She mediates between the emotional protagonist Werther, who is immortally in love with her, and Albert, her fiancée and Werther's adversary with opposite characteristics. A central aspect of the Werther Project is the identification of this triad by visualizing the character constellation in the original text and the literary adaptations, as well as detection of deviations.

Method

For the determination of character relations, name lists were derived from Goethe's epistolary novel and its adaptations in close reading. This lexicon-based approach leads to better results than machine learning techniques for named-entity recognition, since complex entities ("Graf C." or "Frau von S.") which exist in the original text have to be determined without doubt. For each character we paid attention to synonyms (e.g. Lotte, Lottgen, Lottchen) and in case of the Werther character we added the personal pronoun "I", due to the first-person narration. Connections are established when two named entities are located at an adjustable distance of n tokens (normalization, stop word removal or sentence borders can be set as parameters). Based on this simple heuristic approach, the typical triad can be identified in both Goethe's *Werther* (fig. 1) and in Ulrich Plenzdorf's modern adaptation *Die neuen Leiden des jungen W.* (fig. 2) from 1972. Another constitutive element of the plot is the addressee of the messages (Wilhelm/Willi) of the Werther character (Werther/Edgar). With respect to the triangular relationship, we aim to compare the vectors of a single pair, like Werther-Lotte in Goethe's novel, with a corresponding pair, e.g. Edgar-Charlie in Plenzdorf's adaption.

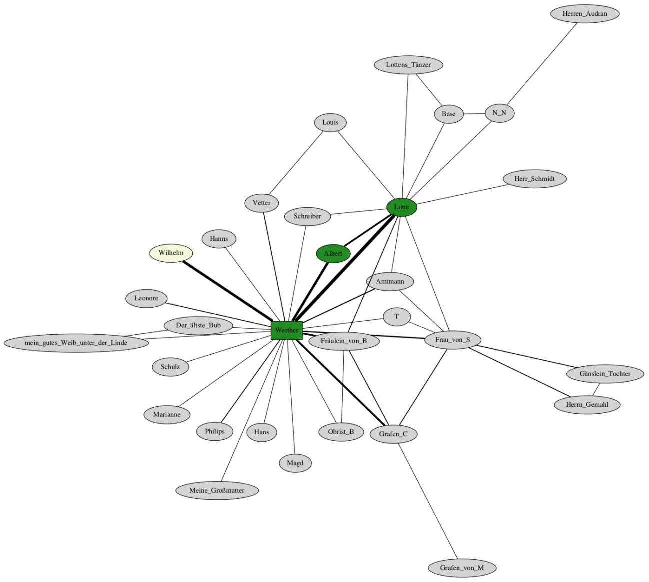

Figure 1: Character network Die Leiden des jungen Werthers (1774); Distance for connections: 8 tokens

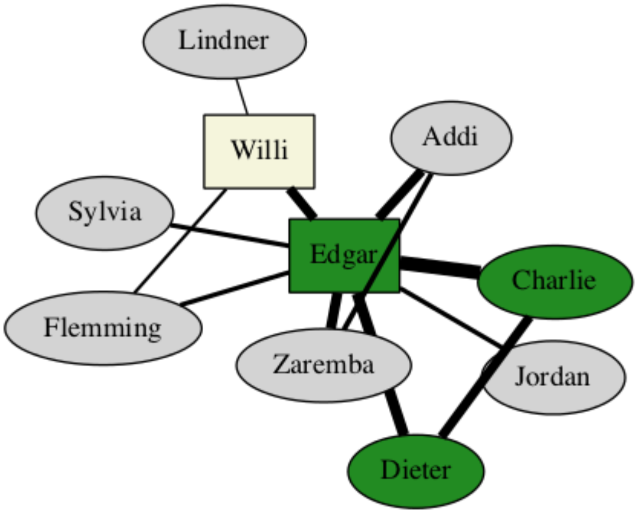

Figure 2: Weighted network of Die neuen Leiden des jungen W. (1972); Distance for connections: 8 tokens

Edgar, the Werther character in Plenzdorf's adaption, takes the central node with the highest degree (the maximum number of connections, cf. fig 3). We noticed a slightly different position of the beloved women in both texts: In Goethe's Werther Lotte appears to be very well connected with other nodes, compared to Charlie in Plenzdorf's novel, who is only in contact with Edgar and his antagonist Dieter (cf. fig. 2).

Die neuen Leiden des jungen W. produces a denser network based on fewer character nodes with more weighted edges. That means Edgar has relatively intense contact to other characters besides his message partner. In contrast, many more characters appear in Goethe's novel, but often only once in connection with Werther, which reduces the network's density.

Average Degree	2.95	2.4
Maximum Degree	21 (Werther)	8 (Edgar)
Density	0.089	0.27

Figure 3: Network measures

Future prospects

The character constellation is determined by an opposition of the sensitive Werther to the rational opponent character Albert, with their love interest Lotte displaying character traits of both. Furthermore, an examination of the relationship pairs with regard to their context is planned.

The usefulness of such an approach is illustrated by the sentence below, which defines the relationship of Lotte and Werther in context:

> **Sie** [Lotte] stand auf ihrem Ellenbogen gestützt und ihr Blick durchdrang die Gegend,

> **sie** sah gen Himmel und auf mich, **ich** [Werther] sah
> ihr Auge tränenvoll, sie legte ihre
> Hand auf die meinige und sagte — **Klopstock!**

The term "Klopstock" is distinctive for the “Werther-Lotte” pair. It reflects their spiritual kinship and characterizes their relationship. However, this expression is found exactly once in Goethe's epistolary novel. Overall, the "Werther-Lotte" pair appears 81 times in the text. Based on these instances we aim to characterize their relationship even with specific terms like "Tanze", "Porträt" or “Klopstock”. This will complete the network visualization of the characters with a description of their individual relations, both in Goethe’s novel and its adaptations.

Acknowledgements

As noted in the Introduction, the Werther Project is part of CRETA, a research center connecting both scholars from Humanities/Social Sciences and Computational Linguistics/Computer Science at the University of Stuttgart. We are grateful to the German Federal Ministry of Education and Research (BMBF) for its generous funding in the years 2016 until 2018 (funding reference number: 01UG1601)

Introduction

Visualization of text can be a useful exploration tool for looking at the corpus of a poet, especially when dealing with a prolific author with a large body of output over the years. In this work, we describe a flexible and extensible tool for analyzing the corpus of a poet, and make a case study of Nâzım Hikmet Ran. Since poetry has its own challenges over plain text, we have developed novel ways of visualizing the structure, the rhythm and affective tone of each poem, as well as ways of looking at the continuities (or discontinuities) of features in the entire corpus over the years. The designed system integrates a database for holding meta-information, and a website for creating and linking interactive, parameterized visualizations.

Nâzım Hikmet Ran is one of the most famous poets of Turkey. Although he was a great patriot, he has spent many years in prison and in exile due to his communistic political views. His poetry is translated into more than fifty languages. We believe this tool can be particularly useful to compare different translations of the poet’s work, to see how certain stylistic or semantic features are retained (or lost) during translations.

Related Work

Most poetry visualizations focus on the aesthetics of information rather than the functional aspects. An example is Diana Lange’s visualizations that transform individual poems into beautiful visual displays, resembling flowers. A similar project is Boris Müller's Poetry on the Road, which turns a text into an image through an arbitrary transformation function, for instance by treating every word as a location and creating a heat map of the entire text. The outcomes of these projects do not tell us much about the poets or the œuvres in question.

In contrast to such artful renderings of poems, there are studies that focus solely on the grammatical and structural problems of poetry writing. Such studies rather try to find quantitative ways to analyze poems, enabling a computational approach for the evaluation of technical quality and subtlety of the rhymes (Opara, 2014; Dalvean2015). In the same line of research, there are visualization tools such as Graphwave, SentimentGraph, SentimentWheel and Ambiances (Meneses and Furuta, 2015). Such visualization examples constitute the starting point of our explorations for devising a new visualization system that is both scalable and modular in nature, i.e. a tool that would accommodate different natural language processing (NLP) tools, as well as new visualization techniques.

Methodology

In this section, we briefly describe the database structure, as well as the software tools used to create the system.

Database

After his death, Nâzım Hikmet's collected works appeared in a single volume (Nâzım, 2007). The digital version of this volume is not publicly available, but we received a special permission from the publishers to use this volume.

Nâzım is a poet who paid special attention to the visual structure of his poems and it is imperative to retain this structure as accurately as possible. Consequently, line indentations were kept intact for each line, as well as the fonts of the individual words. We also paid attention to the fact that the collected works included some text written in prose. Thus, the database structure, depicted in Fig. 1, is entirely hierarchical and ordered according to books, works in a book, lines in a work, words in a line, and characters in the words. This may seem to be an extensively elaborate representation, but it allows detailed structural analysis, as well as the analysis of visual and rhythmic features of each work.

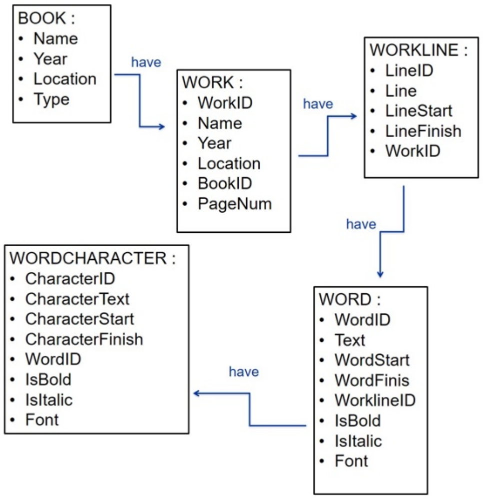

Fig. 1: Database structure.

Software

Since the project involves a dynamic, parametric and interactive system, many software technologies were used. To keep structured data, user data and web page related content, a MySQL database was used. A Turkish-based affect analysis tool was integrated with the system, and Perl was employed to read and parse data for the affect analysis tool. The main programing language of the project is Java and all back end code is also developed in this language. The Spring Framework was used to create the model-view-controller (MVC) structure of the application. In the front end of the application, AngularJS was used to create the MVC structure and to create a single page application. Moreover, to make the application responsive, CSS3 and Bootstrap technologies were used for mobile phone support.

NLP Challenges

In order to parse Nâzım's corpus, a Turkish Morphological Parser and Disambiguator was used (Sak et al., 2008). With the help of this tool, we get part of speech tags of the words, as well as some grammatical information about verbs (i.e. conjugation and tense) and about words' grammatical number. For certain instances, the morphological parser suggests more than one form or number. To solve such problematic instances, an off-the-shelf disambiguator was used. The results of this disambiguation tool suggests the most appropriate form for a given context, which helps in making a decision on the preferred form of a given verb, noun, or pronoun.

The system was enhanced with a text-based affect analysis tool, which returns valence, arousal and dominance values for a given sentence and each word in that sentence (Aydın Oktay et al., 2015). One of the challenges in parsing poems versus prose texts is the lack of a specific notation for indicating the end of a sentence. For the sake of simplicity, each line of a given poem was treated as a sentence, and valence, arousal and dominance values were computed for every word and line individually. These values are stored in the database for fast retrieval.

The System Interface

The generated system works as an interactive visualization tool with a web interface. For the user experience of the web system, a responsive interface is prepared that can even be reached via smart phones. Also, to keep data alive and to allow flexible operations, a single page application is created, with which users can surf between different tabs without losing information. The system design is modular and expandable, as each work unit is separated such that new visualizations can be easily added to the system. The system can also be tailored to visualize a new database easily. The only requirement is that the work of the artist be parsed in the same hierarchical way, and placed on a SQL-capable database.

Visualizations

One of the motivations behind the visualizations is to give information about the analysis on the corpus of Nâzım, and other poets when the database is expanded by the addition of new authors. The tool incorporates a search function, and allows different visualizations to be prepared from the results of the search. Most of the prepared visualizations are interactive charts. They can be used for showing a term's usage over the years, over geographic locations and over publications. The search can be conducted on a collection of works, or in a single work. A separate page was created for searching for a sequence of words, and to prepare comparative visualizations.

We briefly describe two visualizations here to serve as examples. The first visualization is called the "poetry barcode" (see Fig. 2). In this visualization, one poem is visualized, and each line of the poem is represented by a horizontal line. The length and the color of the lines are set according to NLP and affect analysis results, and the lines form six different columns, which show the change of line lengths, usage of active/passive phrases in a line, inflections of words in a line according to person information, as well as valence, arousal, and dominance values of each line.

Nâzım has a lot of stylistic features in his poems. To be able to analyze and extract these features, we have prepared visualizations about the usage of alliteration and his unique verse structure. Alliteration is a stylistic device, in which a number of words, having the same consonant sounds, occur close together in a series. To quantify alliteration, a measure was developed that uses the background frequency of each letter in the poet's corpus. By using a sliding window based evaluation, letter frequencies are calculated, and compared with the base frequency of that letter in the corpus. Fig. 3 illustrates the automatic alliteration detection. Fig. 4 shows a number of additional visualizations in a bird's eye view, including a visualization about passive/active voice usage.

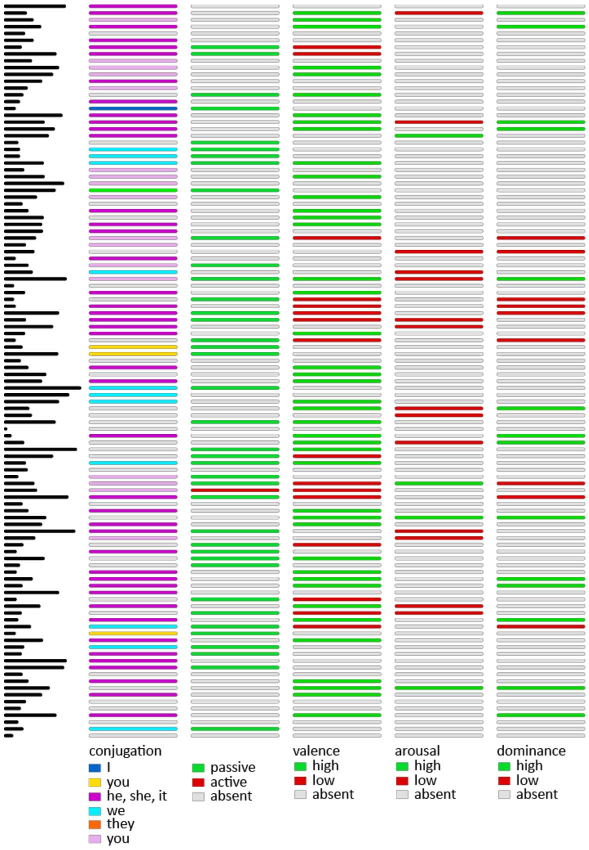

Fig. 2: A poem's barcode, visualizing the structure of the poem together with verb conjugations, passive/active verb usage, and emotional tone.

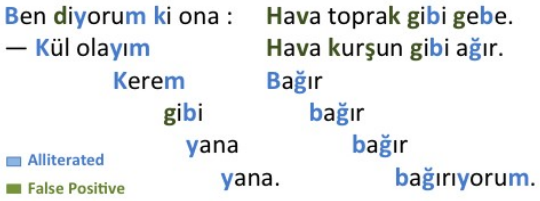

Ben diyorum ki ona :
— Kül olayım
Kerem
gibi
yana
yana.

Hava toprak gibi gebe.
Hava kurşun gibi ağır.
Bağır
bağır
bağır
bağırıyorum.

Fig. 3: Visualizing alliteration in the poem. Best viewed in color.

Conclusions

A complete web page opened to the wider public is in construction, as it requires some security features due to copyrights of the works in the database. But the system is operational in the offline mode, and already provides many visualization options.

Since the database contains composition years and places for poems (where available), it is possible to search for words that are historically relevant for Nâzım. To give an example, a search for the words "hürriyet," (freedom) and "hapis" (jail) restricted to 1919-1938 and 1938-1963, we can easily see that these words' usages are significantly increasing after 1938, when he was arrested for the first time. Other possible uses include the visualization of words associated with different colors, prominent in his poetry, over the years.

The proposed system keeps data and visualizations separate, but well-connected. This enables the addition of new artists to the proposed system. The tool also can be used as a platform to evaluate poetry translation. We show grammatical and affective features of the words in some visualizations like the "poetry barcode". It is possible to use these visualizations to get an idea about translation quality in literal translations, where the emphasis is on word-for-word translation.

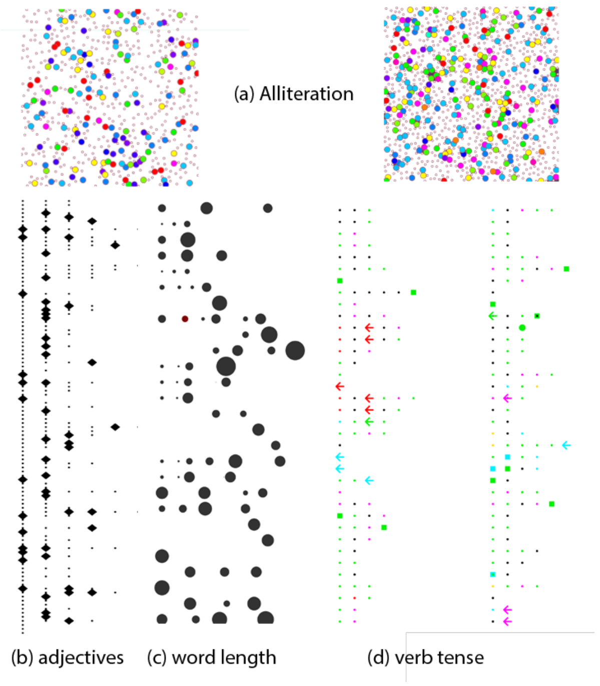

Fig. 4: A bird's eye view of several visualization options in the system. Best viewed in color.

Acknowledgments

We would like to thank Yapı Kredi Yayınları for giving us permission to use the digital version of Nâzım's works. This study is realized in collaboration with Nâzım Hikmet Kültür ve Sanat Araştırma Merkezi.

Introduction

Cinema as a new cultural industry at the dawn of the twentieth century has had a significant impact on the social, cultural and economic infrastructures of modernizing societies. Although cinema from its first emergence was widely adopted, the penetration of cinemas on the exhibition market (number of cinemas, attendance figures) has shown remarkable differences between European countries. Considering the density of cinema theatres and attendance figures as a marker for market penetration, in particular The Netherlands and Belgium stand out: while Belgium abounded in cinemas and film attendance, cinema density and attendance in the Netherlands were traditionally low (Biltereyst and Meers, 2007).

Several scholars have attempted to explain these differences in market penetration, yet no comprehensive, satisfactory explanation has hitherto been found. The low cinema density and attendance in The Netherlands has been explained from the organization of society in various religious and ideological 'pillars' (pillarization) that, until at least the 1970s, compartmentalized the social, cultural, economic and political spheres of society but that excluded the cinema market, that operated 'neutrally' (Dibbets, 2006). However, in similarly compartementalized Flanders a pillarized cinema landscape was successfully created (Biltereyst and Meers, 2007). Others have pointed out that class might have been a possible factor (Thissen and Van der Velden, 2009). Finally, the organization and economics of the industry have been identified as influencing the distribution of cinema theatres (Dibbets, 2006; Boter and Pafort-Overduin, 2009).

Central question

In the context of the research project CINEMAPS the authors aim to map cinema markets in the Netherlands and Flanders in the 1950s, 1960s and 1970s in a comparative study, combining a geospatial analysis of cinema density in both areas with data on pillarization, class and the organization and economics of industry. By projecting these data on historical maps in QGIS, the geographical distribution of different types of cinemas can be compared with patterns in cinema-going and local governmental policies in both countries. This multi-layered, international map functions as a heuristic tool to identify those areas that are interesting for further, in-depth analysis of the factors that explain the differences in market penetration. As such, the project will provide an answer to the core question of how the development of the cinema, as a specific cultural industry, interrelates with the social and cultural dimensions of modern public life in The Netherlands and Flanders, in particular pillarization, class and organization and economics of the industry. In this short paper we discuss our approach and method and present the first results.

Method

In the past decade, the use of GIS mapping technologies has proven a productive tool for analyzing the geo-spatial dimensions of cinema culture (Horak, 2016). The use of mapping is coherent with recent spatial orientations in film-historical scholarship, which “focuses on cinema as social experience, conditioned by factors such as transportation networks, ethnicity, and social group as well as cinema architecture, ticket prices, and the changing patterns of work and leisure.” (Hallam and Roberts, 2014: 20) Such a comprehensive, spatial approach can help to understand how cinema was experienced in the past and how cinema-going influenced the construction of social identity.

The use of GIS technology allows us to study the interrelation between cinema location and the social and economic dimensions of cinema culture at an unprecedented scale. For the comparative research on The Netherland and Flanders, we adopt a three-tiered approach. First, we map all the cinemas according to their typologies, distinguishing between permanent theatres, theatres with occasional screenings and travelling cinemas. Second, while acknowledging the fact that cartels such as the Netherlands Cinema Alliance (hereafter: NBB) extended a strong control over the cinema market (Van Oort, 2016), we also include local government data on the map, to acknowledge the influence of pillarized municipal policy on local cinema cultures. Finally, we map (expected) audiences in relation to their political ideology, religious denomination and income or class. In order to account for the limitations of geospatial technologies in explaining complex human cultural interaction (Verhoeven et al., 2009), in the next phase of our research we will use these maps to identify case studies for further, in-depth analysis.

Mapping cinema density in its socio-economic context – first results

The datasets used (census data, data on religious denomination, local election results, the Cinema Context and Verlichte Stad cinema databases) partly had to be digitized, and all of them had to be harmonized. The harmonization processes consists of equaling the granularity of comparison both nationally and internationally (e.g., comparing municipalities and cantons), the classification of categories (typologies of cinemas, political parties, and religious denomination), and solving discrepancies in periodization between the different datasets. For some datasets harmonization models are available (e.g., for religious orientation), for others they need to be created. The data on cinema locations in Flanders are currently being georeferenced and combined with the harmonized census data and other social datasets.

Since the Dutch data were most complete, in the first phase of the project we focused on mapping cinema density in the Netherlands. The map in Figure 1 shows the geographical distribution of Dutch commercial cinemas in relation to the expected cinema attendance. In general, we can conclude that the distribution of cinemas correlates with the level of expected cinema attendance: many permanent theatres in areas with a high expected attendance, mostly travelling cinemas in areas with a low expected attendance. This is not the case for the area in the middle and East of the country (cities of Apeldoorn and Enschede), which couples high attendance to low cinema density. This invites further research into the particularities of those areas.

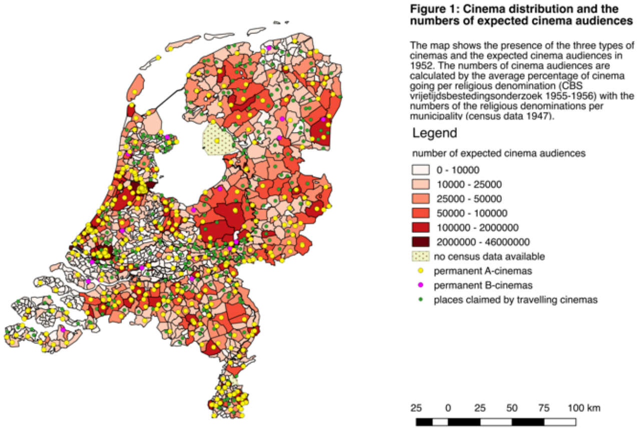

Figure 1: Cinema distribution and the numbers of expected cinema audiences

The map shows the presence of the three types of cinemas and the expected cinema audiences in 1952. The numbers of cinema audiences are calculated by the average percentage of cinema going per religious denomination (CBS vrijetijdsbestedingsonderzoek 1955-1956) with the numbers of the religious denominations per municipality (census data 1947).

Besides the influence of the organization and economics of the industry on the distribution of cinema theatres by the NBB, the local municipal policies were another major influence on cinemas and film screenings. Municipalities issued or refused permits for opening cinemas. Besides, they could prohibit certain film titles by arguing that they presented a threat to local order. Lastly, municipalities could impose (high) local taxes on cinema screenings. In short, this hitherto ignored data provides insights on the influence of pillarization on the distribution of cinemas.

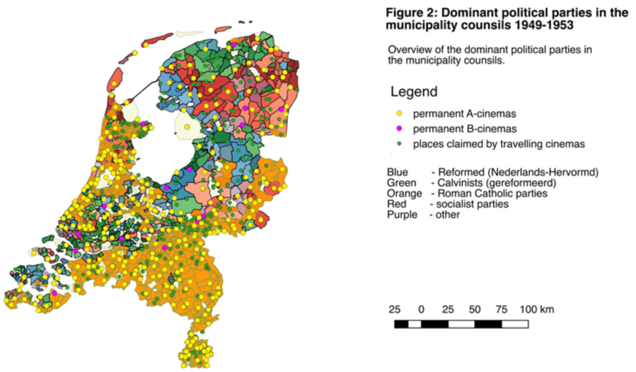

Figure 2: Dominant political parties in the municipality counsils 1949-1953

Overview of the dominant political parties in the municipality counsils.
Legend
● permanent A-cinemas
● permanent B-cinemas
● places claimed by travelling cinemas
Blue - Reformed (Nederlands-Hervormd)
Green - Calvinists (gereformeerd)
Orange - Roman Catholic parties
Red - socialist parties
Purple - other
25 0 25 50 75 100 km

The map in Figure 2 shows a correlation between protestant municipalities (known for discouraging cinema attendance) and low cinema density, whilst Catholic municipalities show a higher number of cinemas. This suggests that religious orientation did influence cinema market penetration, in spite of the supposed neutralizing role of the NBB.

Conclusions and future work

The first geospatial analysis of Dutch cinema culture yielded a number of preliminary conclusions. First, when identifying the data on Dutch cinema locations, it turned out that previous studies had ignored the large number of commercial cinema screenings in places frequented by travelling cinemas (310 in 1949). Although these cinema screenings constitute only a small percentage of the total cinema attendance (1%), the presence of these travelling cinemas does give rise to revisit the assumption that cinema density in the Netherlands was extremely low. Second, in some areas we see a high level of expected cinema-going, but very few cinema theatres - this can be researched further by combining the analysis with data on income and class of the expected audience, as well as further in-depth case study analysis. Third, the mapping of cinema density in relation to religious orientation questioned the assumption that pillarization was not relevant because of the neutralizing role of the NBB. These findings invite a more fine-grained study of local policies as well as film programming. In the next phase we will extend this study by comparing the Dutch cinema market to the Belgian one and use this comparative research to identify case studies for more in-depth research of local specificities of (not) going to the movies.

Text Mining the History of Information Politics Through Thousands of Swedish Governmental Official Reports

Fredrik Norén
fredrik.noren@umu.se
Umeå University, Sweden

Roger Mähler
roger.mahler@umu.se
Humlab, Umeå University, Sweden

How did "information", a concept and a keyword that we take for granted in our modern vocabulary, emerge into the official language? In a previous article for a special issue on digital methods in the journal *Nordicom-Information*, I analyzed the "voice" of the Swedish state and the concept of information in the twentieth century by topic modeling the collection of Swedish Governmental Official Reports (8 000 reports, 1922–). The scope and the long time-span of the corpora makes it an internationally unique source, especially when it comes to study the emergence of interests and attitudes of a single state through time. My results revealed that a topic of information barely existed before the 1960s, then dramatically exploded in frequency, and became a dominant part and parcel in the governmental discourse. In this presentation, I will show how, for example, the rise of an information topic should be understood in relation to a larger, and changing discursive context of Swedish politics.

The findings in this talk result from examining *co-occurring* topics, a less common approach within the practical use of probabilistic topic modeling. A method was used to challenge the previous historiography of information politics by situating an information topic within a larger cluster of topics, so called meta-topics, in all governmental reports from the 1960s, 1970s and 1980s. Studying co-occurring topics is important in order to better understand the nature and quality of probabilistic topic models, as well as the source material that topics represent (e.g. Kaufman 2016).

In collaboration with Humlab, the digital humanities center at Umeå University, and software developer Roger Mähler, topic modeling with Latent Dirichlet Allocation (LDA) was utilized to identify local topics (based on chunks of text) in the reports. Each topic was assigned an average weight based on all the local weights in the entire report. In addition, a co-occurrence value was also computed for all topic-pairs found in the entire corpora. The topic modeling was done using Mallet, and the rest of the calculations, using the output from Mallet, were implemented in Python scripts. The resulting data were visualized and explored as networks using the Gephi software.

This method was expected to give insight into three aspects: (1) the number and diversity of reports in which the information topic over time occurred in, (2) to discover and visualize larger cluster of topics to give a topic of information a position, and hence a context, in those clusters, and (3) enrich the analysis by combining distant and close readings. Thus, the presentation emphasizes the need for switching between a quantitative and qualitative approach, and argues that the findings can be used as a starting point for analyzing the concept of information and its contexts in ways that have not and could not have been done before.

The collection of reports was recently digitized by the National Library of Sweden (2015). The system of commission of inquiry constitutes a cornerstone of the Swedish governmental system. Before the government sends a bill to the parliament, they often appoint a commission to investigate different alternatives of the bill, and the result is a governmental report. Due to the long time-span, the reports cover a wide range of political issues. And, it is the rich diversity of political issues that enables us to view the collection as "the voice" of the Swedish state, similar to what Franco Moretti and Dominique Pestre did when they explored the language used in the World Bank Reports (Moretti and Pestre 2015). Today, incalculable amounts of texts (such as this collection of reports) are not only available online but are also searchable, even down to individual words. This creates a challenge for the humanities to potentially re-rewrite parts of history. That is to say, the digital humanities are now tasked with investigating the ways that changes in language, across and within millions of documents, can be linked to– and thus create new understanding of– developments in society (Jockers 2013).

The Swedish Governmental Official Report series are available for public access at *The Riksdag's open data* website (data.riksdagen.se), and part-of-speech tagged versions are available at Språkbanken (spraakbanken.gu.se) as downloadable XML-files. This study extracted the word stem of all nouns from the reports of the 1960s, 1970s and 1980s, which is sufficient for the study of themes in a text. Each report was split into chunks of 1 000 nouns each (following the work of Jockers 2013). Mallet was then used to compute three distinct LDA topic models, one for each decade, and each consisting of 500 topics. Different numbers of topics were tried out before we settled on 500, based on a breadth variety of what was perceived as concrete political issues (topics). A manual review of the generated topics showed that each decade had been assigned a distinctive topic of a general theme of information. The computed average topic weights for each report, based on weights in each chunk, were used to visualize a network of all reports, and their most dominant topics, with weaker report-to-topic links filtered out based on a configurable threshold. Our pre-study showed that LDA topic modeling often computes a very dominant topic with a weight of over 60%, while the weight of the following topics dropped significantly. Hence, a generous threshold of 0.01 was proved to capture both a discursive core as well as its periphery.

The method used in this study showed three things. Firstly, a distinctive theme of information evolved over time in the official language of the Swedish state bureaucracy. By highlighting reports, in which the information topic was dominant, it was clear that the number of reports increased by a fourfold from the 1960s to the 1980s. Also, by categorizing the reports by state minister of origin, it was revealed that the information topic was associated with growing numbers of political issues over time.

Secondly, the three datasets, one for each decade, were imported, separately, to Gephi. The Force Atlas and Modularity Class algorithms was used to sort topics and reports into larger thematic clusters, or meta-topics. For each topic, the top keywords belonging to a cluster were manually examined as a way to identify the common theme of the topics and the cluster itself. This also allowed for examination of the connections found between the topic of information and other topics and reports.

Thirdly, a distant perspective does not neglect the possibility of adding close reading to the analysis. On the contrary, by zooming in on the topic cluster, it became clear that the reports in which the information topic had a strong presence were often those we least expected. The actual text of reports on foreign policy, research and innovation (among others) presented concrete insights and illustrations of how to understand and synthesize the connection between "information" and various political issues, while also demonstrating the necessity of the concept of information when dealing with various problems and challenges in the post-war society. Hence, the method proved to be a platform for a dynamic interaction between the very close and the very distant that, ideally, could help to strengthen both the quantitative and qualitative perspective as well as the end-result.

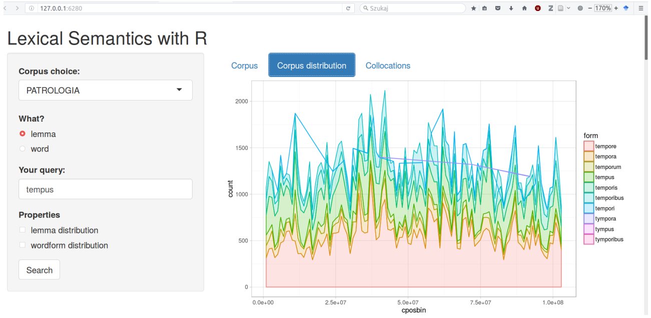
Voces. An R-based Dashboard for Lexical Semantics

Krzysztof Nowak
krzysztof.nowak@ijp-pan.krakow.pl
Institute of Polish Language
Polish Academy of Sciences Krakow, Poland

Introduction

Voces (from Lat. *vox* 'voice', 'word') is an analysis and visualisation dashboard for corpus-based research in lexical semantics. Currently developed as a Shiny application communicating with R session running in the background, *Voces* provides users with possibly exhaustive account of how selected Latin word is distributed across the corpus and what can be told about its meaning. The application is built around a corpus which currently consists of ca. 200M words from texts dating from the Classical era (1 BCE) to the Middle Ages (14th CE). Although *Voces* was originally conceived as a tool of historical semantics research, the application - due to its modular design - may be modified and the code basis can be re-used in new research contexts.



Lexical Semantics with R

Corpus choice: PATROLOGIA

What?
● lemma
○ word

Your query: tempus

Properties
□ lemma distribution
□ wordform distribution

Fig. 1: Voces. User Interface: Word Form Distribution (tempus 'time')

Information computed on a basis of a CWB-indexed corpus is presented to a user through a single-page interface composed of separate widgets arranged in a clear grid layout. Each widget is responsible for displaying in textual or graphical form a clear-cut property of word's distribution or meaning. A heavy use of data visualisation techniques renders *Voces* a convenient tool for exploratory analysis of textual corpora, but the grid layout is also reflection of modular architecture of the application. Each widget is implemented as a separate function which can be extended and adopted by researchers with even limited R programming skills.

Use scenarios

A typical use scenario is triggered when the user specifies a lemma to be looked up. If the search fails, a list of lemmas to choose from is provided. In case of success, neatly separated sections of the dashboard are populated with widgets, each of which corresponds to one sense or distributional property of the word under scrutiny.

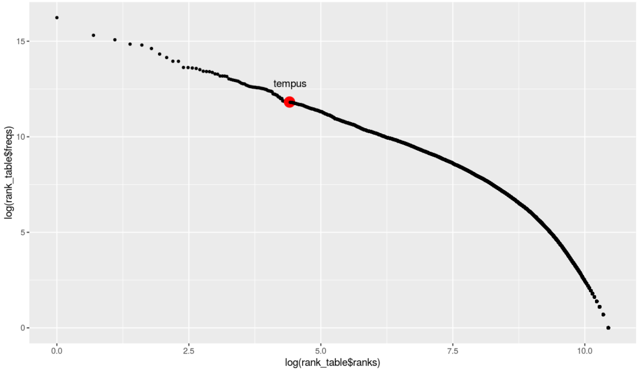


Fig. 2: Voces. User Interface: Frequency Spectrum Plot (Voces. User Interface (tempus 'time')

Word's frequency is summarised as a number of occurrences in the corpus (both raw and p.m.w. counts) and displayed as a highlighted point on a frequency spectrum plot (Baayen 2001). A barplot is provided for investigating change of frequency in subsequent corpus sections. Study of language variation is enabled through widgets presenting word's frequency as a function of such variables as author, work, genre, and – most importantly – time. Users are, therefore, provided with a list of authors who use the word most frequently or a word cloud summarising terms to be found in the titles of works with a particularly frequent use of the word under scrutiny. Genre variation is presented in form of a pie chart, while diachronic dimension - through a bar plot of frequency counts in partitions of the corpus. Diatopic variation study is still to be implemented.

A word's meaning potential can be investigated by means of a set of widgets presenting its contextual properties. The most frequent co-occurrences are enumerated on a simple count list which may be further analysed according to period and genre criteria. A Distributional Semantics Model (Baroni and Lenci 2010) is built from the corpus in order to enable simple meaning computation. Evert's (2014) *wordspace* package and a set of Alain Guerreau's scripts is employed in order to cluster co-occurrences. Similar terms of a looked up word are also computed and then presented in both textual and graphical form.

Users are supported in data and visualisation interpretation through hints which accompany every widget. Their role is to explain not only what the data can mean, but also how the figures were computed, how one can interpret the geometrical properties of a plot, and so on. This, along with the availability of data sets, code snippets, and reports generated on the fly, is what makes *Voces* a tool of reproductive research.

Architecture

Voces was built as a Shiny application (Chang et al. 2016). Its development was greatly facilitated by the availability of a decent documentation and community support (both particularly useful when dealing with framework's complex reactivity model). It turned out soon, however, that it may not be the best choice for web application which has to combine heterogeneous data and non-R code as well. Hence, other solutions are being tested at the moment, those in particular which would provide, for example, more flexible integration of external APIs. The most promising seems to be OpenCPU (Ooms 2014), an application which exposes R session through a RESTful API. This approach allows any application written in some of the less or more popular web development frameworks to easily communicate with an R server instance.

As for the architecture, *Voces* depends on a CQP server instance running in the background which requires corpora to be indexed with the CWB. Communication of the R server with the CWB is assured through the rcqp package (Desgraupes and Loiseau 2012) which offers a set of useful functions providing access to both positional (token-level) and structural (document-level) attributes. Unfortunately, development of this very helpful tool seems to be less active recently and thus *Voces* will soon accept also tabular data as input.

Previous research

Nowadays, corpus linguists may chose from a vast array of free, open source and stable corpus query systems (CQS) which not only allow for efficient indexing of large corpora, but also provide a user-friendly concordance interface and offer out-of-the-box a set of such essential functionalities as collocation lists, simple corpus statistics etc. Both web (CQPweb, NoSketchEngine *etc.*) and desktop applications (TXM *etc.*) are also usually equipped with a less or more intuitive corpus management interface. *Voces*, a dashboard for vocabulary research, is not yet another CQS and has no intention to supersede well-established tools which cannot be easily combated in terms of either robustness or speed. Quite the contrary, the application communicates with the CWB engine and adapts some of the design choices and features of the popular CQS, while hopefully does not inherit their drawbacks.

Unlike the case of the well-known CQS, more emphasis has been put on quick access to multifaceted information rather than on close analysis of occurrences. *Voces* does not attempt, then, to implement some of the features which are traditionally considered an important part of the corpus analytical toolbox, such as concordance sampling, sorting etc. Undoubtedly, the strength of popular CQS lies in their wide applicability: by default, they do not preclude any research scenario. Although agnostic of linguistic theory, *Voces* was originally built for more specific purposes and focuses on semantic properties of the word and its distribution.

What is believed to be one of the main advantages of the present application is that - thanks to its modular architecture - it can be easily extended or adopted by a researcher with even moderate programming skills. In that *Voces* attempts to fill the gap that exists between, on the one hand, fully-blown CQS, which are normally quite conservative when it comes to adding new features, and, on the other hand, single-purpose research workflows built *ad hoc* by researchers. What also distinguishes *Voces* from other CQS is its emphasis on helping users to interpret data. A system of visual and textual hints keeps a researcher informed about where does the data come from, how have they been computed *etc*.

The grid layout is well-known from analytical environment and is especially popular in finances or engineering (Few 2013); in humanities it was adopted, among others, in the Voyant Tools project. It offers a quick insight into otherwise dispersed data and a coherent account of word's properties.

Further research

Voces is currently in an early stage of development. The work focuses on adding new functionalities and plotting types which may sometimes affect application's efficiency. Future work will focus on: (1) optimising user experience; (2) implementing tools for (a) comparative (ie. two-lemma) research and (b) tracking language change; (3) better processing user input (multi-word search).

Motivation

How does mass media affect the way we think about controversial topics such as the “Arab Spring”? What persuasive role do metaphors play especially in opinion pieces?

During the events of the years 2010–2011 in the Middle East & North Africa region a new discourse was established in the German media; immediately these events were assessed as a “wave” of democratization and liberation, and have been metaphorically labeled “Arab Spring”. Metaphors were frequently used to categorize and understand these events (Möller, 2014; Núñez, 2014).

Given the premise that mass media organizes (Couldry, 2010) and shapes social reality (Luhmann, 1996), we analyze how the Arab Spring is categorized and assessed using metaphorical constructions in newspaper opinion pieces. We show ways in which particularly the use of metaphors reveals how the media tried to achieve acceptance for the events based on our cultural models (Quinn and Holland, 1987), which are grounded on our western knowledge.

According to the *Conceptual Metaphor Theory* (Lakoff and Johnson, 1980) metaphors are ubiquitous and exhibit a binary source-target domain structure. The knowledge that we choose to function as a source domain illustrates which conventionalized, overt or tacit knowledge we require to understand new or abstract domains (target domains) in terms of our cultural imprints. Metaphors are instantiated on the text surface and give us clues toward our knowledge basis. Thus, the required knowledge can be described in terms of ubiquitous metaphorical patterns that function as semantic “anchors” in texts, and in terms of conceptual knowledge clusters that function as an intertextual semantic knowledge structure.

As such, we constructed a pipeline that automatically detects metaphors appearing within certain grammatical constructions, before clustering them by presumed source and target domains. The results give us insights into how the Arab Spring is metaphorically structured by semantic clusters in opinion pieces.

Corpus and annotation

Our corpus consists of 300 opinion pieces (Ramge and Schuster, 2001) from five German newspapers, *Frankfurter Rundschau, Die Zeit, Der Spiegel, taz,* and *Die Welt*, which have been written between December 2010 and November 2011 and cover the Arab Spring.

In nine of these opinion pieces, two of this abstract’s authors annotated following grammatical constructions whether they constitute metaphors: adjective-noun (AN) pairs (e.g. “Tunisian spark”), and genitive constructions (GEN) (e.g. “torch of freedom”). Due to their interrelated components they provide a good insight into the structural systematicity of metaphorical mappings (source domain → target domain). The difficulty of the task is reflected in a low inter-annotator agreement (0.45 Krippendorff's α).

Common sources of annotation disagreement included heavily conventionalized metaphors such as "social network", personifications like "self-consciousness of a generation", and metaphors that need a larger context to function. As gold standard for further training and evaluation we only use the agreed upon annotations ("annotated", Table 1).

	Sentences	AN constructions	AN metaphors	GEN constructions	GEN metaphors
annotated	538	968	116 (12%)	102	29 (28%)
complete	11402	19573	-	2758	-

Table 1: Constructions and metaphors in the corpus.

Technical realization

To examine our questions quantitatively, we contrast two approaches to automatically detect metaphors, namely random forests and multilayer-perceptron. The extracted metaphors are subsequently clustered (Figure 1). To extract AN and GEN constructions we first perform automatic preprocessing, including part-of-speech tagging and dependency parsing.

The random forests approach of Tsvetkov (2014) firmly roots in conceptual metaphor theory, mainly employing features extracted from manually crafted resources such as an abstractness wordlist and supersenses, to classify adjective-noun and subject-verb-object constructions. For use on other languages than English, a bilingual dictionary is required. We manually expand an existing dictionary to cover our corpus, and extend their system to classify GEN metaphors.

The described feature-rich approach will be compared – with regards to what (kind of) metaphors can be found – to the shallow neural network approach by Do Dinh and Gurevych (2016), which does not presuppose any specific metaphor theory. It thus does not make use of external features, but rather learns exclusively from given annotations and their context. Preliminary experiments show that more training data is needed for this bottom-up approach.

To gain further insight into usage of metaphor in our corpus, we cluster the automatically found metaphors – resp. their components – into coarse-grained semantic fields. While there are works using a theory-supported top-down approach, e.g. using source domain lists (Gordon et al., 2015), we employ a rather unsupervised approach, without preselecting the number of clusters or manually fixing cluster centers (similar to Shutova et al. (2010), who use spectral clustering for metaphor detection). To that end, we employ Affinity Propagation (Frey and Dueck, 2007), which we supply with cosine similarities between pre-trained word embeddings (Reimers et al., 2014) of the metaphor components.

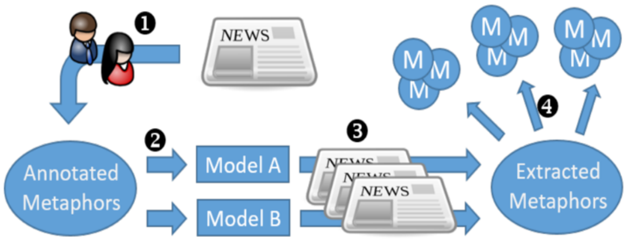

Figure 1: Few newspaper opinion pieces are annotated (1) and the obtained metaphors are used to learn different models A and B (2) (Tsvetkov, 2014; Do Dinh & Gurevych, 2016). These models are then applied to more articles to extract metaphors (3), which are subsequently clustered (4).

Experiments and discussion

We use cross-validation for the intrinsic evaluation of the metaphor detection part. For GEN metaphors, the tested system achieves 0.63 precision, 0.25 recall, and 0.35 F_1-score, with similar performance for AN metaphors. While these results seem low, the actual output of the system when trained on all annotated instances looks promising, and the precision is improved by filtering based on named entities.

Kopf: *Schwertern* des Islams, *Köpfen* des verhassten Regimes, *Handlanger* des Regimes, *Schlägern* des Regimes, *Arm* des alten Regimes, *Zähne* eines Kamms, *Kugeln* des Regimes, *Brust* des Leblosen, *Gesicht* des Exzesses, *Gesicht* der EZB, *Gesicht* des Arabischen Frühlings, *Gesicht* arabischer Demokratien, *Gesichter* der Demonstranten, *Gesichter* der Jasmin-Revolution, *Gesicht* der Revolution, *Gesicht* der Muslimbruderschaft, *Gesicht* der ägyptischen Revolution, *Gesicht* des Landes, *Gesicht* der tunesischen Revolution, *Gesicht* der USA, *Gesicht* ihres Sohnes, *Gesichter* der Vermissten, *Fortsatz* des alten Regimes, *Wand* der Angst, *Loch* der Diktatur, *Schweine* des Regimes, *Augen* vieler Araber, *Hände* des israelfeindlichen Regimes, *Hand* der Sozialisten, *Hände* des Obersten Kommandorates, *Händen* der Börse

Figure 2: GEN metaphors clustered by first noun, with center "Kopf", hinting at conceptual metaphor POLITICAL SYSTEMS ARE BODIES

The clustering creates an impression of which knowledge (source domain) is required for abstract concepts (target domains), and how abstract concepts are "perspectivized" in the corpus, while also giving an overview of occurring intertextual metaphors. Although the cluster assignment and the metaphor detection leave room for improvement (e.g. Figure 2: "face of her son"), the clusters already reveal the systematicity and constraints of metaphorical mappings. Thus, they point to strategies of newspapers that come along with the choice of the (conceptual) source domain.

In Figure 2, bodily parts such as *face*, *head*, *hand* are used as source domains and mapped to political systems or processes (e.g. *regime, democracy, revolution*). This mapping draws on a long tradition in political and philosophical history (Musolff, 2004): *head* and *face* play a central role in our culture – comparing political processes with *faces* or *heads* conceptualize them as human beings. In this cluster the construction *face of* indicates that the events are important, thus construed as worthy to support.

Those prototypical examples for ontological metaphors also support the premise of embodied cognition (Johnson, 1987; Rohrer, 2010).

Sturm: *Schlussphase* des alten Regimes, *Sturm* des arabischen Umbruchs, *Sturm* der Moleküle, *Sturm* der Entrüstung, *Inseln* der Diktatur, *Insel* der Stabilität, *Wind* der Freiheit, *Wind* der Demokratie, *Wind* der Revolution, *Wind* des Wandels

Figure 3: GEN metaphors clustered by first noun, with center "Sturm", hinting at conceptual metaphor POLITICAL SYSTEMS/PROCESSES/VALUES ARE NATURAL ELEMENTS

The positive properties and the movement character of natural elements such as *wind* and *storm* are mapped to the abstract (political) nouns *freedom*, *revolution,* or *change*. They receive a deontic (Hermanns, 1994) character, whereas *dictatorship* is conceptualized in terms of *island* which stands for inertia and stability (Figure 3). These examples already show how the chosen metaphors shape dualistic tendencies by categorizing the events on one hand as a dynamic movement (*wind, storm*) that has to be supported by western democracies, or on the other hand pleading for stability (*island*), thus implicitly supporting dictatorship.

The analyzed clusters and metaphorical conceptualizations indicate a network of source domains that function as key concepts which structure the discourse of the Arab Spring, an assumption we will focus on in future work.

Conclusion and future work

Our study indicates that metaphorical constructions are important in media because of their ubiquitous use in opinion pieces. The generic extracted source domains already suggest that a specific network of knowledge is used in media to highlight certain political aspects of the Arab Spring. Furthermore, they illustrate how contents are emotionalized and ideologized during these events by metaphors and their framing effects. Usage of natural elements or body parts reduces complexity and conceptualizes the events as an organic development, in short: the Arab states become western democratic states. Thus contributing to the extension of western ideology, metaphors impart implicit cultural values. Combining our cognitive and discourse analytical questions we can summarize that the used "bottom-up" clustering is very helpful to get an explorative impression of the "intertextual consistencies" (Verschuren, 2012: 179) of chosen metaphors. They are good textual "anchors" and starting points to investigate the widespread metaphorical use, and thus knowledge domains, in corpora.

With regard to the state of the art, corpus-based methodologies within the Digital Humanities community will benefit from our research by gaining the possibility to automatically compare thematic corpora by using the relationship of their metaphors to the common main cluster as a metric, therefore obtaining a new way to analyze the conceptual network being used. Our approach can help to facilitate corpus studies, e.g. by analyzing other discourse segments which deal with the implicit construction of identity and alterity within opinion pieces by using metaphors.

In our presentation we will highlight the results and give a structured impression of the mappings and the implications of the used metaphors in our corpus and present in short our methodological basis.

In future studies we will compare the conceptualization strategies of the Arab Spring and "Refugee Crisis" in German media, since we assume that the same metaphors and the same (metaphorical) interpretation patterns occur. Further, we plan to investigate another theory of metaphor which is based on Black (1954, 1977) and Gehring (2010). The latter model is strongly interweaved with current discussions about "Begriff" (Müller-Meiningen and Schmieder, 2016; Gehring, 2005, 2010) and discusses its ideological implication(s). Furthermore, the emphasis is placed on the function of metaphors as an epistemological tool by investigating, amongst others, the evolution of ideas and cultural values, e.g. in the historical text collection "Natur&Staat" (1903-11).

Introduction

JazzCats (Jazz Collection of Aggregated Triples) is a prototype project which uses Linked Open Data (LOD) to support musicological, historical, and prosopographical analyses. It has increased access to (and the openness of) data published online through a twofold process: firstly, information hitherto unavailable to users has been shared and incorporated into the project, and secondly, data previously locked in non-Open types (e.g. PDF) has been published in a machine-readable format, increasing discoverability in the context of the wider Web. Connections between datasets that could only be identified through a human user engaging separately with each existing project have now been made explicit, and the resulting aggregated data is queryable from a single user-interface (UI).

Three projects contribute to *JazzCats*: a social network connecting musicians through various types of relationships is provided by LinkedJazz (Pattuelli, 2016); details of solos within performances (including pitch, key, and chord changes) are available from WJazzD (Pfleiderer et al., 2016); and Body&Soul (Bowen, 2013) is a discography of over 200 recordings. These complementary data contain instance-level overlaps for recordings and musicians. Bringing these resources together has enabled a new type of research question, possible only through using criteria from one dataset to inform and hone results from another.

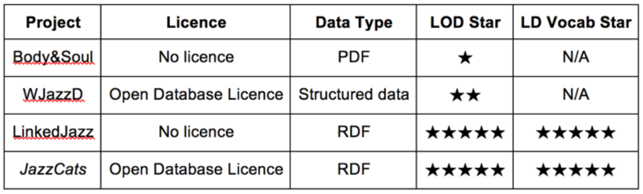
Limitations of existing data publication methods

The sub-projects at the heart of *JazzCats* engage with the 5 Star Standard of LOD (Berners-Lee, 2006) to different extents (see Table 1). The data for Body&Soul has been published online as a PDF, making it an ideal example of 1

Star categorization. WJazzD allows users to download both the database and the software (2 Star). LinkedJazz provides two separate data-dumps of RDF (with an additional, earlier set of triples also available), containing both dereferenced URIs and those which point to human-readable pages. We have categorized this project as 5 Star, because DBpedia resource URIs (related through **owl:sameAs** relationships to LinkedJazz resource URIs) are used (even if the retrieving of additional data from external sources is currently not possible via the LinkedJazz SPARQL endpoint). Publishing the information from the first two datasets with distinct HTTP URIs, connecting them to each other as well as to the RDF acquired from LinkedJazz, makes *JazzCats* 5 Star standard.

Conversion to Linked Data (LD) does not automatically ensure that information is more reusable or discoverable by data consumers on the Web (Bechhofer et al., 2013; Janowicz et al., 2014). Closed systems can benefit from LD, and whilst adherence to the LOD paradigm is an essential criterion for enabling reuse of any project's RDF by other data publishers, effective queries by a wider base of users can be restricted by idiosyncratic or project-unique vocabularies. To encourage good practices, Janowicz et al. (2014) have introduced a 5 Star rating, ranging from LD without vocabulary use (0 Star) to a vocabulary that is linked to by other vocabularies (5 Star). The term vocabulary is used in a broad sense to include all types such as schemata, and ontologies. We have categorized LinkedJazz as 5 Star because it links to other vocabularies and metadata about the vocabulary is available.

JazzCats makes extensive use of properties and classes from other vocabularies, including the Music Ontology (MO) (Raimond et al., 2007), the Event Ontology (Raimond and Abdallah, 2007), FOAF (Brickley and Miller, 2014), and SKOS (Miles et al., 2005). It is currently classified as a 5 Star since metadata about the *JazzCats* ontology is available in a dereferenceable and machine-readable form, but other vocabularies do not yet link to *JazzCats.*



Project	Licence	Data Type	LOD Star	LD Vocab Star
Body&Soul	No licence	PDF	★	N/A
WJazzD	Open Database Licence	Structured data	★★	N/A
LinkedJazz	No licence	RDF	★★★★★	★★★★★
JazzCats	Open Database Licence	RDF	★★★★★	★★★★★

Table 1: Evaluation of the JazzCats composite projects

Increasing accessibility through *JazzCats*

A previously unpublished CSV containing Body&Soul data was cleaned and enriched with additional information held in PDF files using OpenRefine (2013) to create a new, open access dataset (Bangert, 2016). An existing workflow (Nurmikko-Fuller et al., 2016) was then reproduced to map this tabular data into RDF using an Open-Source data integration tool (Web-Karma). This workflow relied on domain expert user-input to complete the ontological modeling and instance mapping stages within Web-Karma (University of Southern California, 2016). To support the future alignment and enrichment of this data with other musicological datasets, the underlying ontological structure extensively utilizes the properties and classes of the MO. The data structure has been documented on the website of the *JazzCats* project (Bangert et al., 2016).

Both the data and the software for WJazzD are available for download from the Jazzomat Research Project website. Although structured data, and in adherence with the 2 Star LOD publication criteria, information in this form is not accessible for machine-inferencing, and the clustered tables can be difficult for human users to navigate. The data was converted to RDF by repeating a second workflow as described in Nurmikko-Fuller et al. (2016) using the D2R server (Cyganiak and Bizer, 2012). This automated process produced clusters of triples based on database information categories (e.g. melody, beats, sections), which are mostly expressed through **xsd:strings** and **xsd:integers**. Mappings were made where applicable to connect these elements together using MO properties and classes. An overview of the ontological structure, and a detailed subsection illustrating the different properties are documented and defined on the *JazzCats* website.

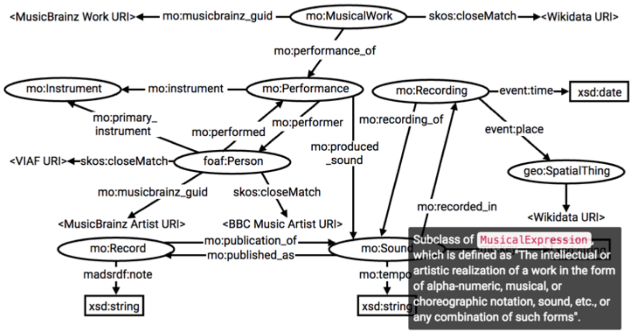
LinkedJazz provides two separate datasets for entities and the 12 different types of interpersonal (both professional and social) relationships between them. Adding these RDF-dumps to the *JazzCats* triplestore enables queries combining this prosopography with performance metadata derived from the other projects which make up the entirety of the *JazzCats* data.

Publishing these datasets as RDF using common vocabularies and ontologies known to have been utilized in other digital musicology projects increases their discoverability and the value. As data publishers, adhering to LOD standards allows us to further benefit from any additional future linkage. A conscious decision has been made at the onset of the *JazzCats* development process to publish RDF, ontologies, and raw data in Open and accessible formats, with appropriate licensing, to allow for the replication of our workflow, verification of our findings, and reuse of any or all of the composite parts of the project. *JazzCats* is made available under the Open Data Commons Open Database License (Miller et al., 2008). The aim throughout has been to produce and publish data that adheres to the FAIR data principles of being findable, accessible, interoperable and reusable (Wilkinson et al., 2016).

Evaluation of *JazzCats*

Although the data in *JazzCats* adheres to a 5 Star standard of LOD for accessibility and openness, the current UI presents a barrier to access for human users. At present, the project RDF (RDF Core Working Group, 2014) is contained within an instance of the Open-Source version of the Virtuoso (OpenLink Software, 2016) triplestore, and is only queryable using the default SPARQL endpoint, accessible from the *JazzCats* website. Example queries demonstrate how results can be generated by drawing from all three datasets simultaneously (Nurmikko-Fuller, 2016), but engagement with the data beyond the parameters set by these existing samples requires the user to have the necessary skills to construct new SPARQL queries (W3C RDF Data Access Working Group, 2008). Aware of the dichotomy of skills between music scholars and the ability to formulate such queries, the authors acknowledge that at present, the site UI presents notable barriers to access.

To address this, we have provided extensive documentation of the underlying ontological structures on the project website. Each of the sub-projects is illustrated with diagrams that include an interactive feature which provides the scope notes for a given class when hovered over with the cursor (see Figures 1-3). The diagrams also show the inherent connectivity of the graphs within *JazzCats*, and the directionality of properties (arrows running from domain to range). The combination of easy access to appropriate documentation for the data, the underlying ontological structure, and examples of functioning queries enables specialists to access *JazzCats* data according to their research interests. In addition, a Pubby interface (Cyganiak and Bizer, 2011) serves as an alternative Linked Data front end that enables users to navigate through the triples without the need to use SPARQL. Influenced by ongoing work at ResearchSpace (Oldman et al., 2016), planned future developments of *JazzCats* include the development of a GUI that will allow users to generate ontologically valid queries using dropdown lists generated by available properties for each class. This step will further help open *JazzCats* for experts and scholars along the full length of the digital humanities spectrum.



Subclass of MusicalExpression, which is defined as "The intellectual or artistic realization of a work in the form of alpha-numeric, musical, or choreographic notation, sound, etc., or any combination of such forms".

Protesters' shouts of "no justice, no peace" ring out over the rows upon rows cars forced a standstill on the 405, one of Los Angeles' busiest highways, on a July night in 2016. This recent protest by Black Lives Matter is notable and representative of an emergent social movement strategy. More than more than half of the 1400 protests relating to Black Lives Matter movement in nearly 300 U.S. and international cities from August 2015 to November 2015 effectively shut down transportation infrastructure (Badger, 2016). This contemporary activist practice can be seen as a logical tactic that shares roots with the historical occupations of schools, restaurants and administrative offices that occurred during protests in the civil rights movement in the United States in the 1960s and 1970s, as an earlier generation of activists rallied against racial segregation. Our proposed project makes accessible for the first time the history of transportation in Los Angeles and demonstrates through interactive maps, archival documents and audiovisual materials, as well as recorded oral history interviews why Los Angeles highways have become a productive site of protest. Contemporary highways are historically situated sites of contestation in which previous generations of racialized communities have paid the high price for Los Angeles' development into a renowned center of both commerce and culture.

Historian Eric Avila's (2014) *Folklore of the Freeway: Race and Revolt in the Modernist City* focuses on the racist highway projects that targeted and sought to isolate minority communities. With origins in the Jim Crow South, he argues, "federally funded highways were instruments of white supremacy, wiping out black neighborhoods with clear but tacit intent" (p. 43). Post-War Los Angeles, like many American cities, saw a rise in the prosperity of white, middle-class Americans who racialized desires and fears led them to towards suburbia in Los Angeles county and beyond. Redlining, restrictive covenants, and other practices of racial discrimination kept the dream of suburban home ownership out of reach of racial minorities. The new American dream came hand in hand with another new phenomenon, traffic. Highways, according to urban planning historian Joseph DiMento (2009), were recommended by urban planners as "the greatest single element in the cure of city ills. The federal government had stepped in by 1956 to cover the construction costs for highways by up to 90 percent. Much of this federal funding was also used by cities to rebuild and "redeem" urban areas (Semuels, 2016). New highways were not only placed not only as to move residents easily into suburbs and to other cities in the region, but were strategically planned and right placed by cities to eradicate what were termed "slums" and "blight," areas heavily populated by persons of color and the poor

(Semuels). Thus highways came to break apart rich and long-standing communities of color in Los Angeles and throughout the United States.

From the Chicano artists' depictions of the highway in East Los Angeles to second-line jazz parade in New Orleans, Avila illustrates how performative activities pleasure and protest by inhabitants remediate the spaces near highways to promote and reflect their own diverse perspectives, practices, and lived realities. East Los Angeles serves an important example of a racialized working-class community threatened by the construction of freeways. In the 1960s, the 60, 10, 101, 710, and 5 Freeways were all extended to cut through the East Los Angeles neighborhood. This environment spawned what Raul Homero Villa has coined as East LA's "expressway generation," from where some of East LA's finest muralists emerged. Throughout the 1970s, ASCO, one of the area's most important Chicano art collectives, used the walls of the freeways as a canvas to paint political slogans, like "Pinchi Placa Come Caca" (Fucking Pigs Eat Shit), "Gringo Laws = Dead Chicanos", "Kill the Pigs", and "Comida Para Todos" (Food For Everyone). ASCO turned these geographical sites of state power, the freeways, into forms of communication that expressed the relationship between spatial formation and racial tension.

The Black Lives Matter movement in Los Angeles has strategically returned to freeways. The press release for a December 23, 2015 protest that shut down a significant section of the 405 Freeway in the Westchester neighborhood explains the reasoning behind blocking freeway traffic. It states, "On one of the busiest travel days of the year, Black Lives Matter is calling for a halt on Christmas as usual in memorial of all of the loved ones we have lost and continue to lose this year to law enforcement violence without justice or recourse" (McReynolds, 2015). Pete White, an organizer with Black Lives Matter and the L.A. Community Action Network, told local news, "In this Christmas season, we're saying there is no mistletoe in our neighborhood, and it's not going to be business as usual" (McReynolds, 2015). Black Lives Matter actions in 2013, 2014, 2015 and 2016 have all resulted in successful and strategic blockages to major thoroughfares, clogging the arteries of the city, and bringing major media and popular attention. The tactical retaking of freeways in a notoriously automobile-driven city is symbolically and materially significant.

We will develop an online interactive repository to provide new access to a descriptive and underrecognized history of political contestation including the urban renewal movements of the mid-20th century, the activism of the expressway generation, and today's Black Lives Matter protests. The necessity of creating and animating this history is most clearly highlighted by the fact that there exists no consolidated archive of the historical images, dates and events related to this phenomenon. Our goal with this project is to provide a resource that would first, document the intersections of freeways, racial justice, and urban social movements in an easily-accessible website and second, promote sustained research and activism relating to this topic. Users are able curate their own path through the repository, for example, by navigating through the map, or scrolling through archival records linked to particular subjects arising within an oral history. This history will be illuminated through the activation of archival documents, video footage, and oral history interviews with individuals who have been involved in the historical development and issues of access intertwined with Los Angeles highways.

The Psalter Project: Providing Mediated Access to Religio-Political Subjects in Early Modern England

Nandra Perry
nandraperry@tamu.edu
Texas A&M University, United States of America

Bryan Paul Tarpley
bptarpley@tamu.edu
Texas A&M University, United States of America

Emerging from the crucible of the religious upheaval that characterizes the English Renaissance is arguably the most influential English book ever printed in terms of its impact on Anglophone religious, literary, popular, and legal culture: *The Book of Common Prayer* (BCP). Encoded within its pages is a kind of algorithm, an annually recurring process, a *ritualization* of both private devotion and public worship for generations of post-Reformation English readers. Taking our cue from Brad Pasanek (*Metaphors of Mind:*

An Eighteenth-Century Dictionary, 2015) and Peter Stallybrass ("Against Thinking." PMLA, Vol. 122, No. 5), both of whom have drawn useful analogies between the database and the commonplace book, we employ the creative anachronism of the "Bible app" to describe the function of the BCP in early modern England. As the first such "app" of its kind, the BCP choreographed religious meaning and ritualized worship for a whole generation of English Bible readers, shaping them into religio-political subjects who were then able to situate their lived experiences within a communally shared time and space. From the perspective of the Early Modern layperson, the BCP provides mediated access to the newly translated biblical text. Of course, from the abstracted perspective of the nascent nation-state of England, the BCP functions as a way to mitigate new anxieties surrounding the democratization of sacred scripture. As the legally established, official means by which sacred text is encountered, the BCP is nothing less than a masterpiece of social engineering.

To extend the metaphor of text as program, the BCP can also be thought of as a class, one which can be inherited and sub-classed, instantiated and "hacked" according to the agenda of particular readers who would produce, via their nuanced reading of BCP ritual, slightly different kinds of subjects according to the specific context in which they find themselves. Of particular interest to the project at hand is a 1586 BCP which has been highly "sub-classed" by one of its owners. Bound together with the prayer book is an entire psalter, whose collection of 150 psalms is cross-referenced in a single hand, which also makes occasional thematic/tonal annotations. In our examination of this prayer book, we wish to develop a methodology for accessing the kind of subject such a "re-engineered" BCP might have produced.

Implied in the very notion of access, of course, is mediation. Within the limited scope of our project, we do not have recourse to the intense amount of labor required to perform a rigorous exegesis of the entire psalter according to how its 16th-century readers might have read it. What we do have, via the psalter's marginalia, is what one (or perhaps two) reader(s) selected as noteworthy in their BCP-regulated practice of reading the Psalms. We also have our own attempts to thematize and register the tone of those same texts. Given these assets, we attempt to provide via the Psalter Project a representation of how a subject produced by this prayer book might look *from our perspective*. Our hope is that, despite the inherently mediated nature of such a representation, we might provide students and scholars alike a better understanding of the "programmatic" nature of religious para-texts like the BCP.

The Psalter Project was born out of Dr. Nandra Perry's scholarship in Early Modern English literature in partnership with Bryan Tarpley's work as Lead Software Applications Developer for the Initiative for Digital Humanities, Media, and Culture (IDHMC) at Texas A&M University. Perry's work with the 1586 prayer book led her to apply for a Summer Technical Assistance Grant with the IDHMC, at which point she was awarded some of Tarpley's development time. Together, they (we) designed a relational database schema for recording the cross-references and tags found in the 1586 prayer book, as well as a web-interface for entering and viewing them. A beta version of the project is available for viewing.

Before commencing development on the Psalter Project web app, a survey of extant, web-based tools was performed to determine whether any one tool (or collection of tools) already satisfied our requirements. Given the marginalia we have to work with (a large amount of scriptural cross-references and thematic tags), we wanted a tool to facilitate the capture and analysis of this data. While there are indeed several digital annotation tools available, such as MIT's Annotation Studio, or the University of Virginia's PRISM, none of these tools allow for the rapid entry of scriptural verse range references and tags. Tarpley implemented the database schema by creating a MySQL database and wrote the web application in Python using the Django web framework, as well as other web-related technologies, such as the jQuery Javascript library and the Bootstrap CSS framework. The database and web app are both hosted by the IDHMC's server infrastructure at Texas A&M. As a way of beta-testing the app, Perry then recorded a sampling of the psalter's cross-references and tags, and also included her own tagging of the referenced verses in terms of both thematic content and perceived emotional impact (affect).

While the Psalter Project in still in development both in terms of methodology and finished product, a preliminary sketch of our reader is emerging via the various views made available through the web app. There is a visualization of the thematic and affective tags in the form of tag-clouds weighted by frequency, a view of the most frequently referenced verses along with their tags, a break-down of all referenced verses (and associated tags) by any specific thematic or affective tag, a presentation of the network of referenced verses (and associated tags) by any specific verse, and a presentation of any of the 150 Psalms in its entirety where referenced verses can be hovered over, displaying tags and referenced verses. At this initial stage, we believe that this multi-faceted portrayal is revealing a reader with a profound sense of group identity as the loyal subject of a just God who provides deliverance to the deserving and punishment to "bad" subjects and oppressive outsiders. The effect, it would seem, is the sacralization of a religio-politics in which the reader's relationship to God is analogous to his/her relationship to the nation-state (and vice versa), thereby justifying, in turn, a posture of hostility toward outsiders and "bad" subjects.

With this paper, we intend to not only provide a more fully fleshed-out representation of the Early Modern religio-political English subject, but to interrogate the various assumptions and methodologies we use to provide this representation so that we might improve the Psalter Project web application. We hope to be able to provide this web application (both in terms of an open- source repository and as an IDHMC hosted web service) to other scholars in the future, so that they too might be able to provide (mediated) access to religio-political subjects.

Medieval Textual Transmission Modeling in Unity3D

Lynn Ramey
lynn.ramey@vanderbilt.edu
Vanderbilt University, United States

How did texts and ideas circulate within and between societies in the Middle Ages? We know that there were many potential vectors of movement: pilgrimage, crusade, merchant caravans and ships, and itinerant performers, to name a few. However, particularly in societies where transmission was largely oral, scholars usually cannot identify specific moments and locations when stories moved from one location to the next. For the medieval period, this lack of data has historically been the cause of heated debates as scholars identify stories that share common elements, but due to historical or political reasons they are resistant to any notion that one nation's literary tradition is "indebted" to another. Nonetheless, societies are influenced by art and ideas from around the world, and denying the contributions of global societies to stories that are held dear leads to isolationism and a sense of cultural superiority. In 2016, US Congressman Steve King (R-Iowa) questioned what non-whites have contributed to civilization. I am presenting an early version of a project that aims to address a part of that question, giving an immersive digital experience of what some of those contributions might look like and just when and how they occurred.

My project uses the Unity game engine to create stories of textual transmission. In particular, I am modeling how elements of the Thousand and One Nights could have circulated between East and West via the Lusignan court at the crusader kingdom of Cyprus circa 1194. In collaboration with Professor Sahar Amer (Arabic Studies, University of Sydney), we have identified a story from the Arabic text, The Prince Qamar Al Zaman and Princess Boudour, that shares narrative patterns and tropes with Old French romances *Floire et Blanchefleur, L'Escoufle, Huon de Bordeaux*, and *Miracles de la fille d'un roi.* Of course, each story has unique elements, but some of the striking scenes (dramatic public unveiling of mistaken gender identity) and themes (a princess who cross dresses and becomes an itinerant knight search of her lover only to be such a valiant warrior that she winds up married to her lord's daughter) are repeated. What is the relationship between Princess Boudour and Blanchefleur? Circumventing the theories of Joseph Campbell and Vladimir Propp that stories have basic, shared, "universal" components, we look at cultural context and emphasize variants. Our digital story will research and test various proposed vectors of transmission that ultimately result in the morphing of one story into a different incarnation of the same tale. While we will never have all versions of a story with changes and variations as it moved from one culture to the next, we can find the smoking gun as it were— places, times, and persons that we know participated in the exchange of objects, texts, and people. By making these moments visible we can test theories and vectors of transmission.

For example, in the medieval period stories were often changed slightly to please the patrons who paid for them. Traveling minstrels would insert the names of local lords or knights into the story, likely to increase eventual payment at the end of the evening. Stories might also change to use more familiar geographical locations. More dramatic changes could find their way into via mistakes in translation or understanding of stories that passed from one court to the next. Some scribes and minstrels enjoyed changing tales drastically in order to leave their own mark. Within our 3D environment, users will experience the multicultural and multilingual Lusignan court and its environs. Users must make small decisions that will ultimately result in changes, sometimes dramatic, in the final tale.

By illustrating just a few of the factors that influence storytelling and cultural interaction, we conceptualize two audiences. The first is someone who may not have ever considered how much cultural interchange can happen in simple storytelling. As the user makes choices, he or she sees and experiences directly the storytelling environment, becoming agents in the creation process. Our second audience is the researcher who, while being abstractly aware of all of these factors, may not see the potential impact of textual manipulation on a story important to his or her research. By working through these connections in an immersive environment, researchers will consider the global nature of the movement of ideas and interchanges in other texts.

The project brings together two areas of academic interest: global medieval studies and spatial studies. Both areas have well-developed audiences.

1. This project is part of the Global Middle Ages Project that aims to make apparent the global cultural interactions that took place in the medieval period, a time that is frequently studied in nationalistic isolation with an apparent assumption that before the modern period people did not travel and were not aware of the wider world around them. With its strategic location in the Mediterranean, Cyprus served as a crossroads between east and west in the Middle Ages. Despite their disparate backgrounds, the Cypriots lived together on this relatively small island for centuries. Scholars (Andrews, Carr, Grünbart, Nicolaou-Konnari, Rogge, Schabel, and others) have looked at this multi-cultural space, establishing moments of contact and exchange using artifacts of architecture and art history. We will extend their work using data gathered from literary works.

2. As we create a space where users can experience the past, we must consider that the meaning and experience of that space was likely very different 1000 years ago. Robert Tally, following and modifying the work of Bertrand Westphal, Leonard Goldstein, and others, suggests that perceptions of time and space changed radically about the time that linear perspective arose in artistic works. In a medieval illumination, for instance, one might have snapshots of past, present, and future within one framed block. Foreground and background rest in the same plane. Starting with perspectival drawing, Goldstein suggests that space became experienced as 1) continuous, isotropic, and homogenous; 2) quantifiable; and (3) perceived from the point of view of a single, central observer. As a contrast, a medieval map such as the 1375 Catalan Atlas evinces a different notion of time and space, at least in terms of visual representation. The map simultaneously includes the Queen of Sheba, the three wise men, and the Great Khan from vastly disparate eras (Old Testament, New Testament, and thirteenth century). Distances and landmasses are not measured to a modern sense of scale, though meaning can be induced from the relative sizes given to different areas and cities. Furthermore, we cannot know from which end the viewer was meant to see the map, as the writing and images are oriented in all directions. Space could comprise multiple times and places, and the lack of orientation toward a particular viewer indicates that perhaps multiple perspectives were expected.

In this sense of space, medieval maps share many traits of video game maps, including the relationship between place and object, where time, distance, and proportion vacillate between being important and irrelevant. For Mario in Super Mario Bros., the distance on the map is not proportionate to the difficulty of the task of reaching the next point. On the Catalan Atlas, Sheba and the Three Wise Men are a part of the map because they share space and time since Creation, showing that time unites us (we are all postlapsarian and part of the map of Christian history) and separates us (we can never meet up since we do not exist at the same moment). A video game engine provides a superlative space for modeling these pre-modern notions of time and space that tell us much about how people, ideas, and texts circulated in the medieval Mediterranean.

Introduction

In this talk, we would like to outline a proposal for a shared task (ST) in and for the digital humanities. In general, shared tasks are highly productive frameworks for bringing together different researchers/research groups and, if done in a sensible way, foster interdisciplinary collaboration. They have a tradition in natural language processing (NLP) where organizers define research tasks and settings. In order to cope for the specialties of DH research, we propose a ST that works in two phases, with two distinct target audiences and possible participants.

Generally, this setup allows both "sides" of the DH community to bring in what they do best: Humanities scholars focus on conceptual issues, their description and definition. Computer science researchers focus on technical issues and work towards automatisation (cf. Kuhn & Reiter, 2015). The ideal scenario– that both "sides" of DH contribute to the work in both areas– is challenging to achieve in practice. The shared-task scenario takes this into account and encourages Humanities scholars without access to programming "resources" to contribute to the conceptual phase (Phase 1), while software engineers without interest in literature per se can contribute to the automatisation phase (Phase 2). We believe that this setup can actually lower the entry bar for DH research. Decoupling, however, does not imply strict, un-crossable boundaries: There needs to be interaction between the two phases, which is supported by our mixed organisation team. In particular, this setup allows mixed teams to participate in both phases (and it will be interesting to see how they fare).

In Phase 1 of a shared task, participants with a strong understanding of a specific literary phenomenon (literary studies scholars) work on the creation of annotation guidelines. This allows them to bring in their expertise without worrying about the feasibility of automatisation endeavours or struggling with technical issues. We will compare the different annotation guidelines both qualitatively: by having an in-depth discussion during a workshop, and quantitatively: by measuring inter-annotator agreement. This will result in a community guided selection of annotation guidelines for a set of phenomena. The involvement of the research community in this process guarantees that heterogeneous points of view are taken into account.

The guidelines will then enter Phase 2 to actually make annotations on a semi-large scale. These annotations then enter a "classical" shared task as it is established in the NLP community: Various teams competitively contribute systems whose performances will be evaluated in a quantitative manner.

Given the complexity of many phenomena in literature, we expect the automatisation of such annotations to be an interesting challenge from an engineering perspective. On the other hand, it is an excellent opportunity to initiate the development of tools tailored to the detection of specific phenomena that are relevant for computational literary studies.

This talk has two purposes:

- To discuss these ideas and collect feedback and propositions. This is also an explicit invitation to contribute in the setup of this initiative. We are also welcoming a discussion about the phenomena that should be included.
- To advertise the idea of a shared task and to invite possible participants. The success of STs relies on a certain number of participants. Given that this has never been organized in the DH community before, we want to spread this idea throughout the community to gather estimates of potential participants.

The Importance of Annotations

In computational literary studies, many phenomena cannot directly be detected from the text surface. To find and categorize such phenomena as, for example, the "narrated time" in a novel, it is first necessary to have an in-depth understanding of the text, knowledge about its author or literary conventions, or knowledge of the text's historical context. Therefore, instances of such phenomena need to be annotated either by human experts or software that is tailored to this task.

Unfortunately, many theories describing interesting phenomena are very difficult to apply to real texts. It has been shown numerous times (e.g., Reiter, 2015, Musi et al., 2016) that annotating theories or concepts directly can lead to very poor inter-annotator agreement (IAA): Different annotators have different interpretions of not only the text, but also descriptions of the theoretical concepts. Although subjective annotations have their merit, studying annotations on large scale depends on their consistency, i.e., a high IAA. In addition, many theories are underspecified and provide examples for illustrations only. Creators of annotation guidelines often have to interpret what is meant by a certain statement and extend definitions to cover examples found in real texts.

Annotation guidelines serve as a mediator between the annotators and a theory (that may use specialised vocabulary). Additionally, such guidelines often contain re-appearing instance patterns and their modes of annotation and/or exceptions, as well as many examples from real texts (see below).

We see the creation of annotation guidelines as one of the cornerstones of large scale text analysis in computational literary studies. Additionally, the creation of annotiation guidelines supports systematic disciplinary discussions about concepts and thus may lead to additional findings relevant for the theoretical discourse (e.g., Meister, 1995; Gius and Jacke, forthcoming). Experts from the field literary studies are well-suited to work with annotation guidelines, as annotation of literary phenomena in literary texts can be seen as a special form of close reading.

Phase One: Annotation Guidelines

The Shared Task

In theory, any phenomenon can be addressed in this fashion, as long as it can be defined inter-subjectively, is reasonably frequent, and is of interest in computational literary studies. As a starting point, we propose to address the issue of narrative levels (Pier, 2014). Narrative levels are a core concept in narrative theory (Genette, 1980; Bal, 1997) which in turn has shown to be a promising foundation for automatisation in literary theory (Bögel et al. 2015). The first reason for choosing to examine narrative levels is their ubiquity: every narrative text necessarily consists at least one, most texts contain many narrative levels; each element of a text can be assigned to a specific level. The second reason is our intuition that a definition of "level" in guidelines is as achievable as the automated detection of levels by computers.

Concretely, participating teams are asked to create guidelines for the detection and annotation of a) narrative levels and b) the relation of the narrator(s) to the narrated world (i.e., is the narrator part of the narrated world or not?). Participants are not bound to adhere to a specific narratological theory. The result of this phase, however, will be a fixation on a set of guidelines (that instantiate a theory).

We will select a number of literary narrative texts and provide copyright-free digitized corpora. All “official” texts (development and test sets) will be English literary texts. Naturally, the second step will be to extend this framework to other languages and/or phenomena.

Evaluation

In NLP shared tasks, the predictions of the systems are compared against a fixed test set– the “gold standard”. Since there is no gold standard in Phase 1, we will evaluate the guidelines using an unseen data set. Each participating team annotates this set using their own guidelines before the guidelines are submitted. Submitted guidelines will be anonymized and re-distributed among the participants. Each participant is asked to annotate the evaluation data set using two other annotation guidelines. In addition, we will be collecting annotations from students.

The evaluation data set will thus be annotated according to each participant’s guidelines four times (1x self, 1x student, 2x other participants).

This setup allows direct calculation of inter-annotator agreement. However, IAA should be only one aspect in evaluating the guidelines, but not the only one. Therefore, we will submit a workshop at DH 2018 to discuss the submissions and select final ones. This setup also allows the merging of different annotation guidelines as well as adaptation according to the discussion during the workshop. Soon after the workshop, Phase 2 will commence.

Phase Two: Automatic Prediction

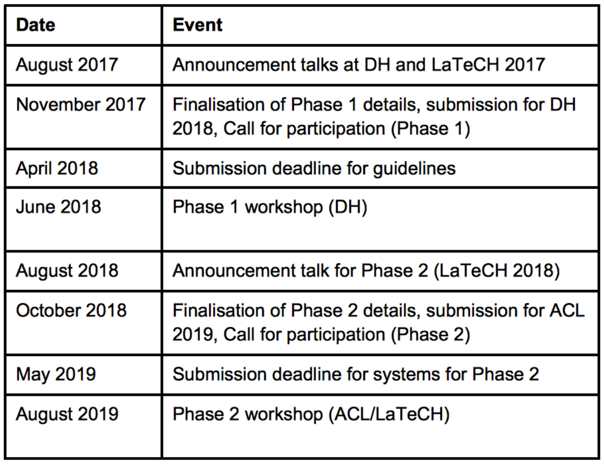
In Phase 2 of this endeavour, the selected guidelines of Phase 1 will be annotated on a large scale by student assistants. Since we do not yet know how long, complex and involved the guidelines will be, there should be close communication between the organizers and the team responsible for the selected guidelines.

As soon as the texts have been annotated, they will be made accessible to participants. For the deadline in Phase 2, participants will be asked to process a new data set – one that has not been released before – and return the predicted annotations to the organizers, who will then make evaluations using standard measures (e.g., accuracy). Finally, there will be a workshop in which each participating team presents its system. This workshop is projected to be coordinated with the LaTeCH workshop series, which has taken place at ACL conferences in the past years (one of the authors of this paper has been a workshop organiser in past years).

There will be no fixation on computational approaches, statistical models, programming languages or environments to tackle this problem. The main benefit of shared tasks towards automatisation is that different approaches can be compared directly. Restricting this possibility space would directly harm the goal.

Technical Details and Timeline

This proposal is innovative in a number of ways: Shared tasks are a new kind of framework in the DH/H community, as such, focalisation have not been investigated in this way before. Last but not least, a shared task with the goal of creating annotation guidelines has not been organized before (to our knowledge). We believe it is more important to do this right than to do this fast, hence we are looking at a rather lengthy timeline.



Date	Event
August 2017	Announcement talks at DH and LaTeCH 2017
November 2017	Finalisation of Phase 1 details, submission for DH 2018, Call for participation (Phase 1)
April 2018	Submission deadline for guidelines
June 2018	Phase 1 workshop (DH)
August 2018	Announcement talk for Phase 2 (LaTeCH 2018)
October 2018	Finalisation of Phase 2 details, submission for ACL 2019, Call for participation (Phase 2)
May 2019	Submission deadline for systems for Phase 2
August 2019	Phase 2 workshop (ACL/LaTeCH)

Attracting enough participants is the main challenge from the organiser's perspective. The main incentives we envision for contributors are excellent publication opportunities: All submitted and generated materials will be published online (open access) under the umbrella of the shared task. Each individual work will be citable. This includes the submitted annotation guidelines, the produced consensus guidelines, and explanation and commentary documents.

In addition to the publication incentive, we believe that our approach is an important contribution towards systematic text analysis in the DH realm. We count on the playfulness and curiosity (in the best sense!) of the DH community to take part in this experiment.

Ngrams Against Agnotology: Combatting Tobacco Industry Narratives About Addiction Through A Quantitative Analysis Of 14 Million Documents

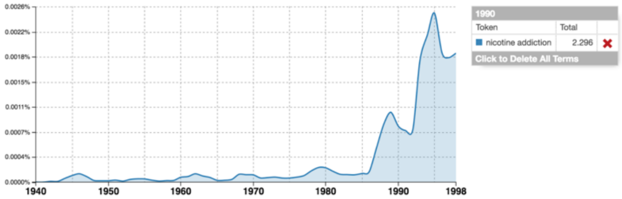
Stephan Risi
risi@stanford.edu
Stanford University, United States of America

What happens when researchers have access to more documents than they could read in a lifetime? As a result of litigation, historians of tobacco have access to over 14 million formerly secret tobacco industry documents, containing incriminating internal memos and research reports but also newspaper clippings and consumer letters (UCSF Library and Center for Knowledge Management). Historians have used this treasure trove to document widespread fraud and systematic deception of smokers by the tobacco industry

(Brandt, 2007; Proctor, 2011). However, industry-friendly historians and tobacco lawyers have started to rewrite some this history by claiming that smokers always knew that smoking is addictive and causes cancer (Brandt, 2007; Proctor, 2011). Usually, these claims rest on a few, well selected documents that support a particular industry claim. Robert Proctor has called processes like this "agnotology," the cultural production of ignorance (Proctor, 2008). Indeed, the arguments of both pro- and anti-tobacco industry historians rely on the same corpus of data: an immense amount of publicly available and full-text searchable documents. Given 14 million documents, there will be some supporting almost any claim.

In this paper, I present one way to counter such agnotological assertions by studying broad trends across millions of documents with frequency analyses. In particular, I counter the claim that smokers always knew that smoking was addictive, an argument often made by tobacco lawyers in court to assign full responsibility to the smoker (Henningfield, Rose, & Zeller, 2006) To refute this assertion, I use frequency analyses with a validation measure to show that smoking only became widely understood as an addiction in the late 1980s and early 1990s, when scientists recognized that the same neural pathways were involved in dependence to both nicotine and harder drugs like heroin and cocaine. This inscription of addiction into the brain replaced older explanations of why people smoke, like personality traits or an oral fixation. Ultimately, I trace how the neurological understanding of nicotine addiction moved from research laboratories to the public: it led to the Surgeon General's warning labels; it enabled smokers to seek out new nicotine replacement therapies; and it made it possible for smokers to successfully sue the tobacco industry for the first time.

Frequency analysis, popularized by the Google Ngram Viewer, is one of the simplest mathematical tools in the arsenal of the digital humanities (Michel et al, 2011). By calculating the usage frequency of terms and expressions over time, it enables users to get a sense of when a term became more or less important. The mathematical simplicity confers it an important advantage: it scales very well not just to thousands but to millions of documents. For this study, I used all 14 million documents (about 10 billion tokens) dated between 1940 and 1998 to create a publicly available website (Tobacco Analytics), where users can create their run their own frequency analyses, akin to Google ngrams.



Token	Total	
■ nicotine addiction	2.296	✖

Figure 1: Screenshot of the relative frequencies of "nicotine addiction" in the tobacco documents from www.tobacco-analytics.org. The presentation will use a number of these graphs to show that smoking only became understood as an addiction in the late 1980s and early '90s.

The main drawback of this method is that the patterns found in the graphs of the Google Ngram Viewer are hard to validate: Does a spike in a particular year represent a statistically significant event or is it just a fluke? Is it caused by 10 or 1000 documents? I address this problem in two ways: First, I allow users to display the absolute number of appearances of a term by year to give them a sense of the number of documents that cause a spike. Second, I am developing a comparison statistic to calculate z-scores using the Corpus of Historical American English (COHA) (Davies, 2010). By comparing frequencies between the tobacco documents and the reference corpus (COHA), it allows me to calculate when frequencies in the tobacco corpus deviate in a statistically significant way (Darwin, 2008, p. 208-222). Given, for example, the above graph of the relative frequencies of the term "nicotine addiction," z-scores can be used to show that the relative frequencies only started to deviate significantly from the comparison corpus in the 1980s.

The tobacco documents provide us with an opportunity to think through the problems that come with access to millions of secret documents. What if millions of dollars in settlements hinge on historical arguments? What if there are immense financial incentives to make false historical claims: to present narratives that are borne out in a few well selected documents, but which misrepresent the corpus as a whole? In the realm of tobacco, historical arguments and knowledge circulate far outside of academia in courtrooms to sway juries or in policy documents to change legislation. The immense size of the tobacco documents archive makes it possible to find a few documents supporting almost any claim. Findings from one group of documents can cancel out the findings from other documents; statements by one expert discredit those of another one. In these cases, quantitative analyses using the whole corpus can be an arbiter of these claims. They are not sufficient to advance historical arguments in themselves, but they can be used to test and disprove hypotheses made on the basis of a smaller set of documents. The Tobacco Analytics project makes powerful digital humanities tools available to tobacco researchers who may not have a technical background, and it allows historians to trace developments within the tobacco industry by examining the whole corpus with the click of a mouse.

Introduction

Presenting images on the web has a long tradition. The <img>-tag was proposed February 1993 by Marc Andreessen, at this time employed by the National Center for Supercomputing Applications of the University of Illinois at Urbana-Champaign, a pioneering institution for the development of the World Wide Web. Marc Andreessen later founded Netscape, the browser that helped to make the web popular. Its most simple form, the image tag contained an src-attribute containing the URL of the image, such as **<img src="http://dhlab.unibas.ch/imgs/sample.jpg">.** Basically, the mechanism to include images into a website has since remained the same. The dynamic manipulation of the DOM with JavaScript (also a invention introduced by Marc Andreessen and Netscape) allowed users to dynamically add, delete or exchange images within a website. Thus complex web-applications that dealt dynamically with images became possible.

However, while on the side of the browser some scaling is possible, the URL had to address an image file with fixed properties (file format, image size etc.). As the computing power of servers grew, it became possible to render the image on the fly with properties that are passed using the HTTP request (e.g. embedded in the URL or as URL-parameters). Recently, the International Image Interoperability Framework (IIIF) emerged as a standard syntax to pass parameters such as image size in pixels, cropping region, rotation angle and file format using a well-defined URL syntax. The IIIF-standard allows to share image resources between web-applications such as Virtual Research Environments (VRE) in a standardized way. There are quite a few IIIF-compliant image servers around, some using a native implementation, some wrapping image transformation programs using a script language such as python.

By a mandate of the State Secretariat for Education, Research and Innovation (SERI), the Swiss Academy of Humanities and Social Sciences (SAHSS) has created a new institution for the preservation and long-term curation of research data in the humanities (Data and Service Center for the Humanities, DaSCH). It ensures permanent access to research data in order to make it available for further research. A pilot program started in 2013 and has been successfully finished. The DaSCH will be permanently installed on January 1st 2017, to guarantee seamless services. The Digital Humanities Lab (DHLab) of the University of Basel has been mandated with the operation of the new institution. For this purposed, DHLab has developed a flexible platform based on semantic web technologies (RDF, RDFS, OWL). Besides text sources, about 500,000 high-resolution images have been ingested to the system during the pilot phase. We decided to use IIIF for presenting the images in order to maximize the interoperability with external systems. Furthermore, we need to preserve only one image file, since IIIF allows using the archiving master also for dissemination and presentation. However, none of the existing IIIF-compliant servers satisfied our needs.

Design Requirements

Therefore, we decided to design and implement our own IIIF server guided by the following requirements:

- Interoperability with internal databases (e.g. RDF-triplestores, RDBMS etc.) containing annotations, metadata etc. as well as access permissions.
- Preservation of all embedded metadata (e.g. EXIF, XMP, TIFF etc.) during all format conversions
- ICC color profile conversions where necessary
- User authentication compatible with the proposed draft of the IIIF for authentication
- High-performance transformation of images including rotation, format conversions (e.g. 16 bit to 8 bit depth) etc.
- Support of Secure Socket Layer (SSL/https)
- A configurable image cache in order to reduce the computational load on the server
- Support of cross origin resource sharing (CORS)
- Import and transformation of images. The server must be able to import images and convert them to the desired master file format (in our case JPEG2000).
- Features beyond the scope of the IIIF-standard such as adding watermarks, size restrictions etc.
- Integrated simple webserver functionality
- Modular extensibility, e.g. integrating support for RTI imaging (both initial transformation and

serving a web-based RTI-viewer – Fornaro et al, 2016)

Implementation

In order to fulfill these requirements, we decided to use C++11 to develop a native, modular, high performance IIIF-compliant image server. A decisive feature was to make the server scriptable with a script language without compromising on performance. We decided to use Lua, an extremely fast, performing, and extensible script language with a small footprint that has only small overhead. It is widely in use for computer games such as World of Warcraft or Minecraft. In order to support different image file formats, we use open source libraries such as libtiff, libjpeg etc. and a modular, extensible architecture. In order to support the JPEG2000 image format, we rely on the kakadu-library. Unfortunately kakadu is not open source, but it is one of the most performant JPEG2000-libraries available. In addition, when acquiring a license, the full source code is provided. Depending on the licensing model, the free distribution of binary packages is included.

In order to reduce the computational load of the server, an efficient caching service has been implemented. The canonical IIIF-URL is used as key for caching since it is unique for each parameter set of the IIIF request.

The Lua-interpreter has been extended with SIPI-specific functionality. Using configurable routes, a fully IIIF-compliant image server has been implemented with the following features:

- Full support of SSL (https) using the OpenSSL library.
- Preservation of metadata. We use the open source exiv2 library and own parsing/generating routines to bridge the differences between the different image formats.
- ICC profiles are interpreted and converted using the open source "little cms" library.
- Before serving an image, a configurable pre-flight lua-script may be executed. Within this script different tasks can be performed, e.g. querying a database for access rights, adding watermarks, ICC profile conversions etc.
- Native support of JSON Web Tokens. JWT's may be analyzed using simple Lua functions (e.g. in the pre-flight script) for authentication and access control.
- Querying other databases using RESTful services. These RESTful query functions are also exposed to Lua.
- Image upload using HTTP multipart/form-data headers. The upload process and file conversions can be controlled with simple Lua scripts.
- Cache control with a simple web-based administration interface.
- Native support for sqlite3 databases from the embedded Lua.

SIPI is open source and can be found on Github. In order to use the JPEG2000 format, a licensed copy of the kakadu library has to be provided by the user. We will provide an extensive manual and binary downloads (including JPEG2000 support) for all major Linux distributions, OS X and a docker image on http://sipi.io

Conclusion

SIPI is a fully IIIF-compliant native image server which integrates extremely well into existing platforms. The flexibility provided by the embedded scripting language, as well as the features going beyond the IIIF specification, allow the integration of IIIIF-based interoperability into existing imaging platforms and image repositories. The support of the secure socket layer (https) access control is a necessity in the environment of digital humanities.

SIPI can easily be customized and extended for special purposes. Elaborated imaging methods (e.g. support for multi-spectral images, image processing functions etc.) could be implemented using the existing SIPI server as base. However, such enhancements will require extensions to the IIIF-syntax. Further development at the DHLab will include the preprocessing of RTI-images as well support for other media types such as PDF and moving image. We are also working on the implementation of the Amazon S3 client-API in order for SIPI to directly serve images that are stored in a S3 compatible cloud storage.

The project *Mapping the Enlightenment: Intellectual Networks and the Making of Knowledge in the European Periphery* is funded by the Research Centre for Humanities (RCH) for the academic year 2016-2017. The project uses interactive mapping tools for visualising, exploring, and analysing the intellectual and geographical networks developed by Greek-speaking scholars of the Ottoman Empire during the 17th and 18th centuries. Based on the convergence of the latest achievements in digital mapping and historiographical discussions about the representation of the Enlightenment, the project develops user-friendly interactive and dynamic web maps of the itineraries of traveling scholars, and visually represent the building of networks between scientific centers and peripheries. Additionally, this dynamic system provides multi-layered maps that enables users to query and visualize data and flows through a modern and robust environment. This interactive interface offers a simple and effective way of showing how the intellectual networks developed within the European periphery in the 17th and the 18th centuries contributed to the shaping of knowledge during the Enlightenment. The project is a collaboration between the Department of History and Philosophy of Science of the National and Kapodistrian University of Athens and the Centre for Digital Humanities of University College, London.

The theoretical background of the project resides in the history of science. Following the general idea that the knowledge systems that gradually dominated European modernity have come into being through a dynamic and multi-layered process, the project is based on the notion of 'moving localities' introduced by historians involved with the Science and Technology in European Periphery (STEP) network. The concept of 'moving localities' enables historians to perceive circulation as a knowledge production process. Locality, in this sense, indicates a complex set of connections, allegiances and commitments which travel with people and thus extend beyond conventional boundaries, creating interconnected intellectual spaces over wide geographical areas. The sense of locality enables actors to perform distinct cultural identities in the course of their travels that are informed, but not confined by those assigned by their places of origin. Thus, locality can be said to be a local culture made active and open to transformation thanks to encounters fostered by travel conditions.

The project takes advantage of the theories of the STEP network on the one hand and the latest achievements in digital mapping on the other, in order to create a visual representation of the above-mentioned concept of 'moving localities'. The creation of a research tool will contribute to enhancing users' understanding of the emergence of modern science and technology as the expression of a dynamical geography. Addressing the spatiality of knowledge, the project focuses on associating particular cultural traits with specific points on a map, and work on tracking down the various paths and encounters through which such cultural traits and the respective knowledge practices evolved. In this context, centres and peripheries are not regarded as tokens of a steady, hierarchical geography, but rather as mutually dependent and co-constructed entities whose status can change with time.

The development of the user-friendly interactive interface initially focuses on the intellectual and geographical travels of the 18th-century Greek-speaking scholars, who developed an extended network connecting the most important European educational centers with the most important power centers of the Ottoman world. Adopting such an approach allows more historical actors to enter the scene, such as the Portuguese *estrangeirados* and Spanish *pensionados*. The visualisation of the paths followed by the Greek-speaking scholars, the *estrangeirados* and the *pensionados* enriches this historical and digital representation of the Enlightenment in the periphery.

The technical plan aims to use and supports open source software. The project ambitiously strives to make every possible bit of information queryable and visualised. On the server side, Apache, PostgreSQL, PHP and GeoServer with PostGIS library are the principal technologies that are used for the processing and serving of the data. On the client side, the latest versions of the web standards model HTML5, CSS3 and JavaScript provides a modern and user-friendly user interface. Initially, the scholars flow data are processed, normalized and ingested into the geo-enabled PostgreSQL database. The visualisations of the data are materialised using the Leaflet library and other JavaScript libraries such as D3.js, Chart.js etc. The combination of the above technologies gives life to our historical data by combining powerful visualisation components and a data-driven approach to DOM manipulation.

This project does not aim to create visuals and maps per se; instead, it perceives these techniques as the medium to assess and display the findings of historical research that critically challenges the received narrative concerning early modern intellectual European networks. The creation of a visual image of the dynamic, multi-layer process of knowledge-shaping in the European periphery challenges current digital projects which mainly reflect the mainstream positivist histories of the Enlightenment. The intellectual networks developed within and across the periphery are mainly absent from the mainstream histories of the Enlightenment and if they are recognized, they are typically treated as the paths of intellectually parochial scholars who were unable to fully embrace the ideal of modernisation through reason and science. Bringing such figures to the forefront, and confirming their role in the production of scientific and technical knowledge, may help historians tell more nuanced stories about the complex cultural encounters, which molded the European intellectual space and the multifarious knowledge exchanges that shaped the notion of European science and technology. By using modern digital techniques, we aim to enhance the picture of the European periphery as a historiographical standpoint in order to transcend the established spatial hierarchies and bring to the fore the continuous re-inventions, conceptual shifts and cultural adjustments, which are responsible for the shaping of modern scientific and technical knowledge. The proposed project presents an innovative narrative of the making of knowledge during the Enlightenment. At the same time, it constitutes a unique combination of the latest web and mapping technologies, and provides innovative means of storing, transferring, visualising, and querying historical data.

We believe that this project is a perfect example of how Digital Humanities, through its interdisciplinary nature of binding together research in humanities with digital technologies, can generate new critical knowledge through the re-interpretation of data that might otherwise be obscured. In addition, with the use of the latest open-source technology in spatial visualisation, the project adds value to the field by providing a showcase of the evolution of relevant technologies and, more importantly, the ways that Digital Humanities can innovatively use them for research. Finally, the project has the potential to offer a basis for a more ambitious project on a larger scale following the successful completion of its first stage. The ultimate aim is to allow other researchers to submit their data to the open-architected and forward-compatible queryable mapping tool and provide a historically more accurate overview of the intellectual movements during the Enlightenment.

Labex Obvil, Université La Sorbonne, France

Resumé

Nous avons conçu une ontologie destinée à indexer le corpus des œuvres numériques littéraires. Cette ontologie prend en compte les dimensions esthétiques et matérielles des œuvres de sorte que l'analyse critique et la production d'archives se croisent dans la tâche de conservation.

Abstract

Depuis le premier générateur de textes conçu par Theo Lutz en 1959, la littérature créée sur ordinateur n'a cessé de produire des œuvres marquées par le caractère éphémère des logiciels et des ordinateurs. Sitôt le support obsolète, l'objet se désintègre. Les traces laissées par l'œuvre sont le plus souvent frustrantes, à la façon d'une fenêtre à peine ouverte sur un paysage riche en textures, et bientôt close. Les textes critiques comprennent un bref descriptif de l'œuvre, augmenté parfois de quelques captures d'écran. Le lien entre les mots et les images, le dynamisme de dispositifs en constant mouvement, le fonctionnement du programme sont perdus. Jamais les exégèses ne font figurer le code-source, la vie de l'organisme fébrile de l'œuvre numérique est dès sa désagrégation insituable. Les traces laissées par les œuvres numériques sont aussi frustrantes que ces chefs d'œuvres du cinéma muet aujourd'hui seulement disponibles sous forme d'une poignée de photographies, d'un scénario et d'une composition musicale. Ce qui animait et faisait le film manque, et c'est du coup le cœur du dispositif qui n'est plus qu'une vaste lacune, un centre absent. Le parallèle avec le cinéma est pertinent dans la mesure où l'œuvre numérique est mobile, caractérisée par la transformation. La littérature électronique est déjà historiquement riche, tout en étant trouée d'oubli. La bibliothèque est constituée pour une bonne partie d'ouvrages fantômes.

L'obsolescence des supports n'est pas le seul problème d'accès, l'incompatibilité des équipements est également un obstacle important à la lecture des œuvres. Ainsi les chefs d'œuvres de la fiction hypertextuelle *Afternoon, a story* (1987) de Michael Joyce et *Patchwork girl* (1995) de Shelley Jackson ne sont lisibles que sur des ordinateurs Mac. D'autre part, les différences entre ordinateurs peuvent complètement changer la perspective sur l'œuvre, en l'éloignant de l'intentionnalité de l'auteur.

Dès lors se fait jour la nécessité de concevoir un point de référence à ces œuvres changeantes et éphémères, un site électronique qui par-delà l'obsolescence prévisible des logiciels et l'absence d'interopérabilité des systèmes, puisse proposer des traces pertinentes de ces objets fuyants. En somme, la tâche à accomplir revient à archiver une œuvre existante, à la concevoir aujourd'hui même comme un présent révolu, à la considérer dans sa mortalité potentielle. Quand l'archivage est accompli après la désagrégation des œuvres, leurs vestiges consistent en des descriptions lacunaires dans des articles critiques, des images qui sont des fragments des objets numériques, parfois quelques mots sur les programmes. Ces traces manquent de pertinence car elles sont le fruit d'actes isolés, dispersés, et tout à fait fortuits. Des aspects essentiels des œuvres ne sont pas couverts par ces archives parcellaires. En créant l'archivage a priori paradoxal d'une œuvre encore accessible, on se rend maître des traces en cessant d'être soumis aux effets du hasard, on trie les faits saillants d'une esthétique au détriment de propriétés secondaires : « Plutôt que l'idée de conserver certains aspects, il faut se demander quels aspects abandonner » (Rouffineau 2016). Quand l'œuvre disparaîtra, ses traits définitoires seront encore consultables dans le site d'archives.
Un tel site aura plusieurs finalités :

- constituer une mémoire de l'objet numérique
- disposer des substrats pouvant servir de supports pédagogiques
- proposer une pluralité de points de vue sur une œuvre protéiforme
- contribuer à un discours critique visant à la définition d'un genre littéraire

En effet, les archives pourront être utilisées dans un cursus universitaire afin de pallier aux difficultés d'accès aux œuvres, et leur diversité corrigera les distorsions d'ordinateur à ordinateur, qui tendraient à une perspective faussée sur l'objet d'étude.

Dans cette perspective nous avons conçu une ontologie pour indexer les œuvres à partir de leurs différentes caractéristiques, qui constituent autant de points d'entrées aux œuvres littéraires numériques. L'ontologie a été construite à l'aide de l'éditeur Protégé (Kapoor et Sharma, 2010) et elle existe dans le format OWL. La photographie d'écran qui suit en donne une image partielle.

Cette ontologie comporte des descripteurs précisant les concepts de la littérature numérique, les fonctionnements des programmes informatiques associés, les genres littéraires, les modes de conservation possibles, et les propriétés multi-médiatiques des œuvres. Les descripteurs font à la fois état de l'esthétique et de la matérialité des œuvres. Le versant esthétique est représenté par les catégories des concepts et des genres littéraires, qui tentent de circonscrire l'intentionnalité des dispositifs. Le concept est le moteur, la justification de l'entité formelle. Bien que les descripteurs soient nombreux (voir tableau 1), on peut dégager trois familles conceptuelles, allant du complet abandon aux tourbillons de l'écran à la recherche du contrôle sur le texte numérique. La contemplation de l'action de la machine, la fascination technologique, représente le premier ensemble conceptuel, au sein duquel le spectateur suit du regard les découpages textuels opérés par le générateur. Le descripteur « immersion dans le langage » décrit bien une seconde tendance visant à entourer le lecteur/spectateur/internaute de mots à peine visibles, qui vont par exemple se télescoper, un mouvement dont l'effet est de faire perdre à l'utilisateur une vision surplombante par rapport au langage pour faire de cet instrument de sens un facteur de désorientation. La tendance inverse, celle de la recherche d'un contrôle, est bien résumée par le concept de littérature ergodique forgé par Espen Aarseth (1997). La compréhension d'un mécanisme complexe permet l'accès au texte. Cette dernière modalité correspond dans le tableau des genres littéraires au jeu vidéo (voir tableau 2). Les genres littéraires peuvent être classés en quatre regroupements : la poésie visuelle, l'animation, le générateur de textes et le net-art. La poésie visuelle et l'animation se fondent sur des effets immersifs dans le langage, l'interactivité accroît cette dimension. Le générateur de textes délègue à la machine la production littéraire, et le spectateur du net-art s'abandonne à un tissage des flux mis en scène par le programme.

Les descripteurs des fonctionnements (tableau 3), des modes de conservation (tableau 4) et des propriétés multi-médiatiques des œuvres (tableau 5) quittent le champ conceptuel pour s'intéresser à la matérialité des écrans. Les fonctionnements (tableau 3) sont génératifs (le programme produit du texte), interactifs, ou bien une séquence est déroulée (film vidéo, logiciel cartographique), enfin l'ordinateur s'ouvre aux réseaux (liens avec des journaux en ligne). Cinq principaux types de documents sont conservés (tableau 4): le texte, l'image, le son, le parcours sous forme d'enregistrement, le programme (code-source). La dimension textuelle des œuvres (tableau 5) s'articule autour des notions d'appropriation et de transformation, de fragmentation, de couplage entre le signifié et le signifiant graphique. La dimension sonore peut être centrale ou bien un arrière-plan, les descripteurs « musique liée au texte » et « reconnaissance vocale du texte » désignent les œuvres électroniques régulées par ou régulant des fichiers sonores. La dimension visuelle peut être inscrite dans l'apparence du signifiant graphique du texte, peut être autonome mais liée sous forme d'images évoluant au rythme des mots, ou bien l'iconicité est indépendante du langage.

Cette ontologie est le premier pas vers la création de l'interface d'un site d'archives, dans lequel coexisteront des substrats, tels que décrits dans le tableau 4, et des points de vue critiques. Alexandra Saemmer souligne cette nécessaire mise en perspective : « La capture n'est pas suffisante, mais c'est une trace, un document, valorisable par une contextualisation » (Saemmer 2016). Parallèlement à l'étude critique des œuvres, qui situera la pertinence des documents, une recherche de toutes les expériences lectorales, spectatorales, perceptuelles, interactives, sera menée à travers le web. En raison des différences d'ordinateurs, il est nécessaire de puiser dans les nombreux blogs et forums de discussion toutes les descriptions de rencontres et d'interactions avec les œuvres numériques étudiées. En glanant et en organisant ces expériences distinctes voire divergentes, on rend compte de l'œuvre fuyante et protéiforme qu'est l'œuvre numérique, et on sauve de l'oubli des témoignages reposant sur des supports éminemment friables. Les postulats de ces œuvres éphémères dépendant de programmes, seront rendu pérennes par des documents figés qui seront autant d'artefacts de type muséal.

Introduction

Enjambment takes place when a syntactic unit is broken up across two lines of poetry (Domínguez Caparrós, 2000: 103), giving rise to different stylistic effects (e.g. increased emphasis on elements of the broken-up phrase, or contrast between those elements), or creating double interpretations for the enjambed lines (García-Paje, 1991).

In Spanish poetry, the syntactic configurations under which enjambment takes place have been described extensively, and detailed studies on the use of enjambment by individual authors exist (see Martínez Cantón, 2011 for an overview) including, among others Quilis (1964), Domínguez Caparrós, (2000), Paraíso, (2000), Spang (1983) for a description of enjambment, and Alarcos (1966), Senabre (1982), Luján (2006), Martínez Fernández (2010) for case-studies on a single author. However, a larger-scale study to identify enjambment across hundreds of authors spanning several centuries, enabling distant reading (Moretti, 2013), was not previously available.

Given that need, we have developed software, based on Natural Language Processing, that automatically identifies enjambment in Spanish, and applied it to a corpus of approx. 3750 sonnets by ca. 1000 authors, from the 15th to the 19th century. What is the interest of such large-scale automatic analyses of enjambment? First, the literature shows a debate about which specific syntactic units can be considered to trigger enjambment, if split across two lines, and whether lexical and syntactic criteria are sufficient to identify enjambment. Second, the stylistic effects that enjambment permits are also an object of current research (Martínez Fernández, 2010). Systematically collecting large amounts of enjambment examples provides helpful evidence to assess scholars' current claims, and may stimulate novel analyses. Finally, our study complements Navarro's (2016) automatic metrical analyses of Spanish Golden Age sonnets, by covering a wider period and focusing on enjambment.

The abstract is structured thus: First we provide the definition of enjambment adopted. Then, our corpus and system are described, followed by an evaluation of the system. Finally, findings on enjambment in our diachronic sonnet corpus are discussed. The project's website provides details omitted here for space reasons, including samples for the corpus, results, and other details.

Enjambment in Spanish

Syntactic and metrical units often match in poetry. However, this trend has been broken since antiquity for various reasons (Parry (1929) on Homer, or Flores Gómez (1988) on early classical poetry).

In Spanish tradition, enjambment (in Spanish, "encabalgamiento") is considered to take place when a pause suggested by poetic form (e.g. at the end of a line or across hemistichs) occurs between strongly connected lexical or syntactic units, triggering an unnatural cut between those units.

Quilis (1964) performed poetry reading experiments, proposing that the following strongly connected elements give rise to enjambment, should a poetic-form pause break them up:

- **Lexical enjambment:** Breaking up a word. We translated "lexical enjambment" from Quilis's terms "encabalgamiento léxico" or "tmesis".
- **Phrase-bounded enjambment**: Within a phrase, breaking up sequences like "noun + adjective", "verb + adverb", "auxiliary verb + main verb", among others. We translated "phrase-bounded enjambment" from "encabalgamiento sirremático".
- **Cross-clause enjambment:** Between a noun antecedent and the pronoun heading the relative clause that complements the antecedent. We translated "cross-clause enjambment" from Quilis's "encabalgamiento oracional".

The project site includes Quilis's complete list of syntactic environments that can trigger enjambment, as well as the types identified by our system. Besides the enjambment types above, Spang (1983) noted that if a subject or direct object and their related verbs occur in two different lines of poetry, this can also feel unusual for a reader, even if the effect is less pronounced than in the environments identified by Quilis. To differentiate these cases from enjambment proper, Spang calls these cases "enlace", translated here as "expansion".

Quilis (1964) was the only author so far to gather recitation-based experimental evidence on enjambment. His typology is still considered current, and was adopted by later authors, although complementary enjambment typologies have been proposed, as Martínez Cantón (2011) reviews. Our system identifies Quilis' types, besides Spang's expansion cases.

Corpus

The corpus is based on two public online collections from Biblioteca Virtual Cervantes (García González, R. (ed.), 2006a, 2006b). The first one covers 1088 sonnets by 477 authors from the 15th-17th centuries. The second one contains 2673 sonnets by 685 authors from the 19th century. We created scripts to download the poems, remove HTML and extract dates of birth and death for the authors (About 30% of the 15th to 17th century authors had exact dates of birth and death, for the rest only the centuries were available. Among the 19th century authors, ca. 45% had exact dates of birth and death). Table 1 shows the distribution of authors and poems by century. The corpus covers canonical as well as minor authors, inspired in distant reading approaches (Moretti, 2007, 2013).

Period *	Sonnet Count	Sonnet %	Author Count	Author %
14.5	43	1.14	2	0.17
15	2	0.05	2	0.17
15.5	8	0.21	5	0.43
16	141	3.75	58	4.99
16.5	411	10.93	108	9.29
17	478	12.71	300	25.82
17.5	5	0.13	2	0.17
18.5	13	0.35	6	0.52
19	1150	30.58	361	31.07
19.5	1510	40.15	318	27.37
Total	*3761*	*100*	*1162*	*100*

Table 1: Distribution of sonnets and authors per period.

* Exact dates of birth and death are available for a minority of authors; often only the century was provided in the corpus sources. Periods ending in ".5" cover authors who lived in two centuries. E.g. period "15.5" covers authors born in the 15th and deceased in the 16th century

System description

The system has three components: a preprocessing module to format input poems uniformly, an NLP pipeline, and the enjambment-detection module itself.

The NLP pipeline is IXA Pipes (Agerri et al., 2014). Its results for contemporary Spanish are competitive. Our system uses it to obtain part-of-speech tags, syntactic constituency (e.g. verb-phrase, noun-phrase) and syntactic dependencies (e.g. direct object).

The enjambment detection module is rule and dictionary-based, and exploits the information provided by the NLP pipeline. Rules (30 in total) of different characteristics identify enjambed lines, assigning them a type among a list of 12 types, based on the typology in Section 2 (the full list of types identified by the system is available on the project site).

- Some rules are very shallow and only take **parts of speech** into account.
- Some rules additionally exploit **constituency** info.
- Some rules use **dependency** information, e.g. to detect "subject / object / verb" relations.
- For any type of rule, **custom dictionaries** can restrict rule application to a set of terms. E.g. certain verbs govern arguments introduced by one specific preposition; we itemized these verbs and their prepositions in a dictionary, to complement information provided by the NLP pipeline or correct parsing errors.

Enjambment annotations are output in standoff format. Further details can be found on the project's site.

System evaluation and discussion

Test-corpus

To evaluate the system, we created two reference-sets (SonnetEvol and Cantos20th), manually annotating enjambment in them

1. **SonnetEvol**: 100 sonnets (1400 lines) from our diachronic sonnet corpus of ca. 3750 sonnets (Table 2). This test-set contains 260 pairs of enjambed lines (in other words, if there is an enjambment between lines 1 and 2, we consider that as "pair of enjambed lines" in the reference corpus).
2. **Cantos20th**: 1000 lines of 20th century poetry (Colinas, 1983), showing natural contemporary syntax. We identified 277 pairs of enjambed lines.

The distribution of enjambment types in the test-corpora is balanced (Table 2). The SonnetEvol diachronic test-corpus is balanced across periods (Table 3). It should be noted that balancing across periods does not apply to the Cantos20th test-corpus: it covers the 20th century only.

We annotated the Cantos20th corpus in order to assess the system's performance on contemporary Spanish with natural diction, compared to its behaviour with the SonnetEvol corpus, which includes some archaic constructions and often shows an elevated register.

For the evaluation reported here, each sonnet was annotated by a single annotator. Obtaining multiple annotators' input on the same sonnet to assess inter-annotator agreement (Artstein and Poesio, 2008) is part of our ongoing work.

18.5	3
19	17
19.5	8
Total All Periods	*100*

Table 3: Distribution of sonnets by period in the manually annotated SonnetEvol corpus. The 16th, 17th and 19th centuries cover ca. 30% of the corpus each, and the 15th century covers ca. 10% of the sonnets
**Exact dates of birth and death are available for a minority of authors; often only the century was provided in the corpus sources. Periods ending in ".5" cover sonnets for authors who lived in two centuries. E.g. period "15.5" covers sonnets for authors born in the 15th and deceased in the 16th century

Enjambment-detection tasks evaluated

We defined two enjambment-detection tasks:

- **Span-match**: the positions of enjambed lines proposed by the system must match the positions in the reference corpus for a correct result to be counted.
- **Typed span-match**: for a correct result, both the positions and the enjambment type assigned by the system to those positions must match the reference.

System results and discussion

Precision, recall and F1 were obtained. The definitions for Precision (P), Recall (R) and F1 were the usual:

$$F1 = 2\frac{P \cdot R}{P + R}\ ; \quad P = \frac{\text{nbr. of correct outputs}}{\text{nbr. of system outputs}}\ ; \quad R = \frac{\text{nbr. of correct outputs}}{\text{nbr. of reference outputs}}$$

Table 4 provides overall results for both corpora. Table 5 provides the per-type results on the diachronic test-corpus (SonnetEvol). The project's site contains more detailed results (e.g. per-type results for the Cantos20th corpus, or breakdowns for SonnetEvol per period).

Corpus	Task	N	P	R	F1
SonnetEvol	*span-match*	260	74.18	87.64	80.35
	typed span-match		61.24	72.31	66.31
Cantos20th	*span-match*	277	84.01	89.17	86.51
	typed span-match		78.04	83.39	80.63

Table 4: Overall enjambment detection results. Number of test-items, Precision (P), Recall (R) and F1 in our two test-corpora, for the span-match and typed span-match enjambment detection tasks

Enjambment or Expansion Type *	N	P	R	F1
Phrase-Bounded (all types)	*104*	*66.19*	*88.46*	*75.72*
adj_adv	2	100	50.00	66.67
adj_noun	29	54.55	82.76	65.75
adj_prep	14	58.82	71.43	64.52
noun_prep	39	55.36	79.49	65.26
relword	1	100	100	100
verb_adv	5	50.00	100	66.67
verb_cprep	9	83.33	55.56	66.67
verb_chain	5	100	80.00	88.89
Cross-Clause[12]	*23*	*76.00*	*82.61*	*79.17*
Expansions (all types)	*133*	*61.54*	*66.17*	*63.77*
dobj_verb	65	60.00	69.23	64.29
subj_verb	68	63.24	63.24	63.24

Table 5: Enjambment detection results per type. On the SonnetEvol corpus. Number of items per type, Precision (P), Recall (R) and F1 on the typed span-match enjambment detection task.
* The types are described on our site

For untyped detection (span-match), F1 reaches 80% in the SonnetEvol corpus, whereas F1 for typed detection is 66.31%. For the contemporary Spanish corpus (Cantos20th), F1 is higher: 80.63% typed detection, 86.51% span-match. This reflects additional difficulties posed by archaic language and historical varieties for the NLP system whose outputs our enjambment detection relies on. Expansions get lower F1 than phrase-bounded types overall. But we do not think that the F1 difference between SonnetEvol and Cantos20th is due to the higher proportion of expansions in SonnetEvol (Table 2): Results per-type (see the evaluation page of the project's site) show that phrase-bounded enjambment detection is 10 points of F1 lower in SonnetEvol than in Cantos20th. Also, phrase-bounded enjambment results for the 15th-17th period (with more archaic language) are 10 points of F1 lower than in the 19th century.

A common source of error was hyperbaton: the displacement of phrases triggers constituency and dependency parsing errors. Prepositional phrase (PP) attachment also posed challenges: Verbal adjuncts get mistaken for PPs complementing nouns or adjectives. This is a common problem in syntactic parsing, even for contemporary languages (see Agirre et al, 2008, for English). For historical varieties, Stein's (2016) results for verbal adjuncts and prepositional complements in Old French also suggest the difficulties posed by prepositional phrases.

Creating a reparsing module to manage hyperbaton and improve PP attachment results may be fruitful future work.

Scholarly results and discussion

The system's goal is detecting enjambment to help literary research on the phenomenon, via providing systematic evidence for its analysis.

We consider our untyped enjambed-line detection results helpful, given an F1 of ca. 80% on the diachronic test-set. As an example application, we examined the distribution of enjambment according to position in the poem, particularly in positions across a verse-boundary (lines 4-5, 8-9 and 11-12). Comparing the results for the 15th-to-17th centuries vs. the 19th century (Table 6 and Figure 1), we see that enjambment across the tercets increases clearly in the 19th century, with a small increase of enjambment across the quatrains (lines 4-5) and across the octave-sestet divide (lines 8-9). Given the manageable data volume, we validated the counts for enjambment across a verse boundary (Table 6) manually (but not the more voluminous data for all other positions).

The value of the tool is helping perform such analyses on a large corpus. This opens the door for scholars to assess the literary relevance of the findings, and search for the best interpretation.

Enjambed line positions	Scholarly relevance	15th-17th cent.		19th cent.	
		Count	%	Count	%
4-5	across quatrains	2	0.07	19	0.26
8-9	across octave-sestet divide	2	0.07	12	0.16
11-12	across tercets	20	0.72	147	2.01

Table 6: Pairs of enjambed lines across verse boundaries in the 15th-17th vs. the 19th centuries: Counts of enjambed line-pairs and percentages over the total number of enjambed line-pairs for each period. An example of the types of analyses stimulated by automatic enjambment detection

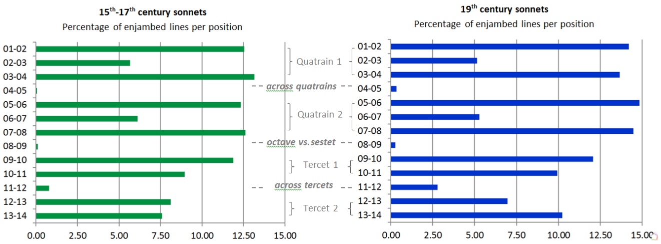

Figure 1: Percentage of enjambments per position in the 15th-17th centuries vs. the 19th.
The y-axis represents line-positions; the x-axis is the percentage of enjambed line-pairs for a position over all enjambed line-pairs in the period. Enjambment across quatrains and across the octave-sestet divide is very rare, with a small increase in the 19th century. The division between the tercets blurs in the 19th century, in the sense that enjambment across them is clearly higher than in the previous period

Outlook

The characterization of enjambment in Spanish literary theory has unclear points. Systematically obtaining enjambment examples is helping us find additional evidence to analyze these unclear points. Moreover, we are not aware of a systematic large-sample study of enjambment across periods, literary movements, or versification types in Spanish, or other languages. Automatic detection can help answer interesting questions in verse theory, which would benefit from a quantitative approach, complementing small-sample analyses. e.g.: To what an extent is enjambment used differently in free verse vs. traditional versification?

Students in our metrics classes are currently annotating enjambment for 450 sonnets. These annotations will permit inter-annotator agreement computation. We will also examine the possibility of using supervised machine learning to train a sequence labeling and classification model to complement our current detection rules.

Acknowledgements

Pablo Ruiz Fabo was supported by a PhD scholarship from Région Île-de-France. We also thank Clara Martínez Cantón's and Borja Navarro's metrics students for their ongoing sonnet annotation work, and Borja Navarro for introducing his students to the annotations required.

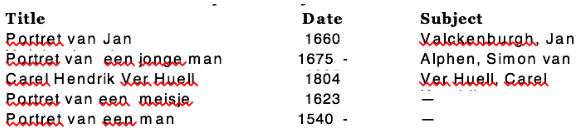
Introduction

The history of color is full of instances of how and why certain colors come to be associated with certain concepts, ideas, politics, status and power. Sometimes the connotations occur arbitrarily, like in the instance when pink was assigned to baby girls, and blue started to be associated with baby boys at the turn of 19th Century [Paoletti, 1987]. Sometimes though, color associations have very tangible reasons, such as in the case of Marian blue, reserved only for painting Virgin Mary over the centuries. The reason is found in the scarcity of the rock lapis lazuli –even more valuable than gold– from which the blue pigments were extracted. Individual colors have convoluted and contested histories, since they have been attached to many symbols at any given time. John Gage, an art historian who has devoted 30 years of research on the topic of color, explains the conundrum of what he terms "politics of color" in a simple fashion: "The same colors, or combinations of colors can, for example, be shown to have held quite antithetical connotations in different periods and cultures, and even at the same time and in the same place."[Gage, 1990].

The purpose of the present study is to introduce a method for automatically extracting color distributions and main colors of paintings, as well as color schemes of people in paintings. By visualizing these over time for cross-referencing with historical data, this study will reveal changes in how particular colors were used in a given time period and culture. In this study, we will look at artworks to find out whether certain colors or tones are associated with a specific sex, and if these connotations change over time. To that end, we apply algorithmic tools to process very large datasets automatically, and information visualization tools to depict the findings.

Related Work

Today, major cultural heritage collections are available online. Digitization and preservation of artworks is an important occupation of museums and cultural heritage institutions, as well as many Digital Humanities projects. Portions of of such digitized collections are made available to further computer vision research in order to scrutinize art historical questions. Such collections are usually enriched with meticulously tagged metadata describing the origins of each artwork. However, these datasets do not provide comprehensive gender annotations. For example, Rijksmuseum's arts database has a wide selection of categories with rich metadata that is primarily about the art objects themselves (see Table 1 – the quantity of meta information and context vary between different art samples), but without any reference to what these artworks hold [Mensink and Van Gemert, 2014]. Automatically determining whether a sitter of a portrait is female or male in a painting is not an easy task.



Title	Date	Subject
Portret van Jan	1660	Valckenburgh, Jan
Portret van een jonge man	1675 -	Alphen, Simon van
Carel Hendrik Ver Huell	1804	Ver Huell, Carel
Portret van een meisje	1623	—
Portret van een man	1540 -	—

Table 1: Sample from Rijksmuseum meta data

Several publications have appeared in recent years with the aim of automatic gender recognition. The survey by Ng et al. described a variety of approaches to gender recognition in natural images [Ng et al., 2012]. Xiong and De la Torre (2013) proposed a practical and effective method for automatically detecting faces in natural or man-made images. Once the face is detected, a supervised classifier is used to determine whether it belongs to a male or female. This requires the ground truth annotation of a large number of face images, from which the automatic classifier learns the visual boundary between these two classes.

There has been focused studies to address face recognition tasks on artistic images [Srinivasan et al., 2015]. For the purposes of face detection, mainstream algorithms perform sufficiently well on paintings that are of interest for this study. Automatic male/female classification is not perfect, it will occasionally get confused and produce an incorrect label. However, over thousands of images, a small number of individual errors will not prevent us from seeing the general patterns of color usage with males and females.

Methodology

In this study, the aim is to analyze the trends of clothing color in different periods, separately for males and females. For this purpose, we work on a database of paintings, for which the era (or date) is provided, and we seek to annotate each image with the gender of the depicted person, as well as a rough segmentation of the area of the clothing. The general workflow of the proposed approach is depicted in Figure 1.

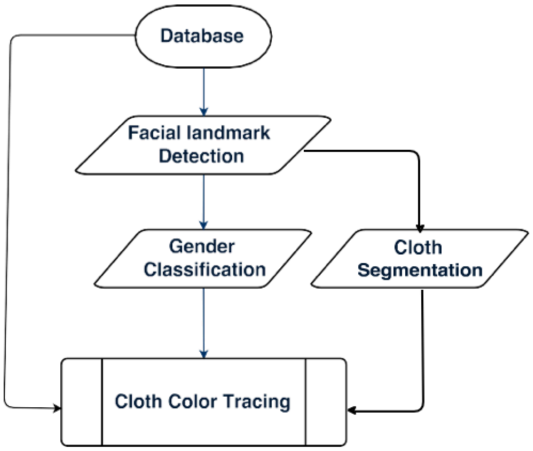


Figure 1. The workflow of the proposed approach.

Database

The Rijksmuseum is a Dutch national museum dedicated to arts and history in Amsterdam. The Rijksmuseum database contains 112.039 high-resolution im- ages with extended meta data [Mensink and Van Gemert, 2014]. However, as mentioned previously in Section 2, the Rijksmuseum database has neither gender nor clothing color information embedded into its metadata. We describe briefly how we determine the missing information.

Gender Classification

We have performed classification of the perceived sex from the face images. This process is commonly called Gender classification in computer vision – not to be mixed with characteristics of masculinity, femininity or sex organs, but what is perceived solely from the face crops on the paintings.

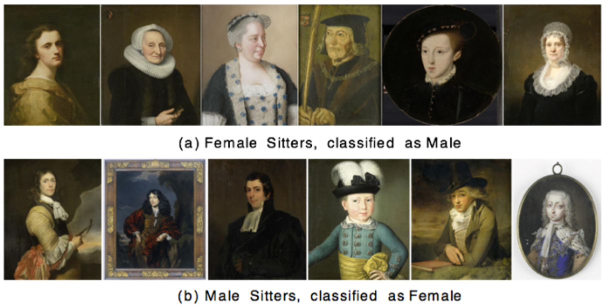
For this purpose we have prepared a test dataset of face images from Rijksmuseum paintings and three training datasets of face images: 10k US Adult Faces[Bainbridge et al., 2013], Labeled faces in the wild[Huang et al., 2007] and in an approach similar to Jia's work [Jia and Cristianini, 2015], we have gen- erated our own IMDB dataset. IMDB dataset images are collected using the Google Image search, using actor and actress names as queries. In total, 5600 male and 5300 female faces were downloaded.

None of the datasets have gender annotations, and hence we have performed face detection and facial landmark extraction methods in [Xiong and De la Torre, 2013], first, then hand-clean face detection and landmark extraction results against false positives and validate gender information (for all 10k US Adult Faces dataset and LFW dataset we had to manually annotate each image, but also Google Image search results for IMDB dataset are not perfectly robust, hence the IMDB dataset also had to be verified). Then we have aligned the faces to a mean shape [Gower, 1975], and extract features that are resistant to illumi- nation effects [Ojala et al., 2002]. We then train a classifier using the sequential minimal optimization (SMO) method [Platt et al., 1998].

The biggest challenge for evaluating gender recognition performance on the paintings is to make sure the ground-truth gender data are actually correct [Mathias et al., 2014]. From our experience, this demanding task requires a full view of the painting, rather than just the detected face. Results of some combinations of the datasets are given in Table 2. We could reach above 75% accuracy on paintings, just by using photographs of actors and actresses in the training of the system. Some of misclassification examples are given in figure 2.

	IMDB	IMDB and 10k	IMDB, 10k and LFW
Female	**62.16%**	62.32%	57.11%
Male	**84.51%**	83.40%	85.79%
Total	**77.21%**	76.41%	76.28%

Table 2. Gender recognition performance on Rijksmuseum. All results are com- parable and best (by small margin) is acquired when only the IMDB dataset is used.



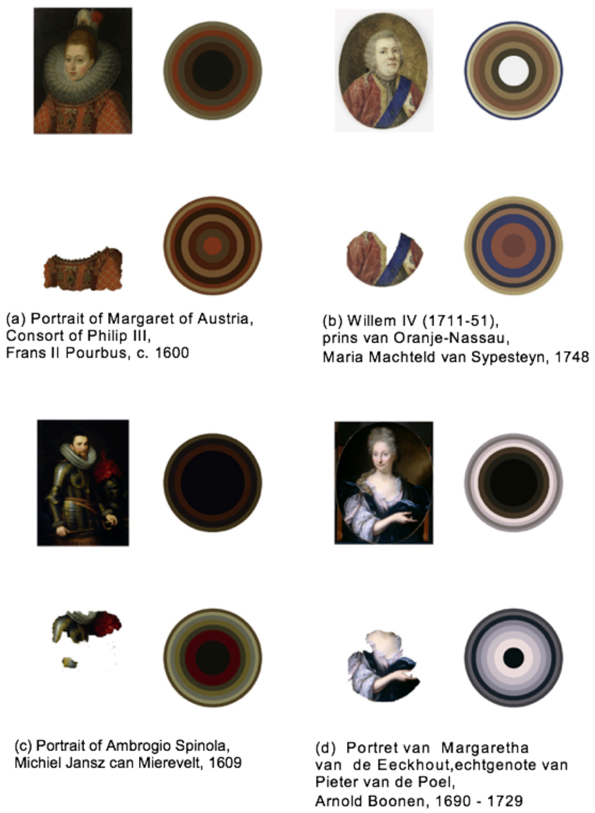
(a) Female Sitters, classified as Male

(b) Male Sitters, classified as Female

Figure 2. Misclassified paintings

Clothing color information

Portrait paintings that are completely focused on the sitter's face have still a lot of background noise that disrupt the color representation of the paintings (see Figure 3). Our hypothesis is that color representation, when focused on the clothing of the model, will still reflect the color scheme that is associated with the gender of the sitter.



(a) Portrait of Margaret of Austria, Consort of Philip III, Frans II Pourbus, c. 1600

(b) Willem IV (1711-51), prins van Oranje-Nassau, Maria Machteld van Sypesteyn, 1748

(c) Portrait of Ambrogio Spinola, Michiel Jansz can Mierevelt, 1609

(d) Portret van Margaretha van de Eeckhout,echtgenote van Pieter van de Poel, Arnold Boonen, 1690 - 1729

Figure 3. Four paintings from the Rijksmuseum collection, classified and segmented in terms of colors.

In order to extract the color information of an outfit we need to do a coarse segmentation of the clothing. We used the GrabCut approach [Rother et al., 2004]. In this method, a user defines an area of interest, as well as foreground and background seeds for the segmentation. In our study, background and foreground seeds are initialized based on the detected face landmarks.

Figure 4 provides an initial visualization of the dominant color distributions for each era, for males and females. Concentric circles have thickness associated with the frequency of the color. Bright colors are relatively rare, as the paintings in our tagged collection are generally dark, with the occasional shaft of light illuminating part of the painting. But a very distinct pattern can be observed in that females wear lighter colors compared to males, and show higher variance over the years. Some painting examples are given in Figure 5.

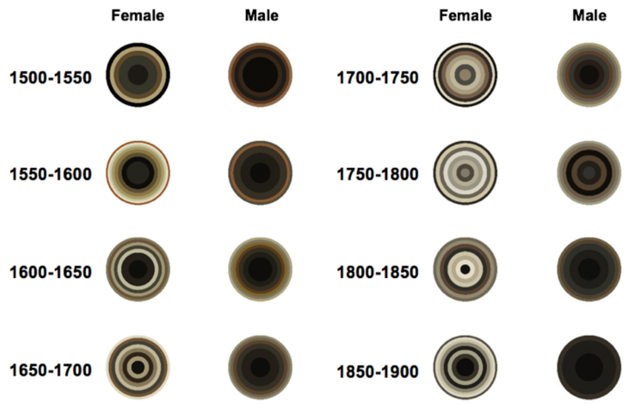


Figure 4. Clothing colors over time. Females wear significantly lighter colors than males. Best viewed in color.

(b) Sample male paintings between 1700 - 1850

Figure 5. Paintings of males and females from the Rijksmuseum database over time. Best viewed in color.

Conclusions

Every period and location has certain dominant color associations and symbolism. To investigate hundreds of thousands paintings in a single sweep requires automatic analysis tools. Our main objective in this work in progress is to perform an analysis on the usage of color for different genders along the centuries, and to develop tools for establishing semantic associations of colors for each particular period of study. With the increased popularity of open-art, this study can be extended significantly by introducing more databases alongside Rijksmuseum, for example, drawing on the Europeana collection [Doerr et al., 2010].

Introduction

In recent years, semantically enhanced Digital Humanities Research has become a widespread topic realized in different environments (e.g. CWRC, Pundit). While semantic graph technologies are mainly used to connect, annotate, query and aggregate strictly formalized entities, there is a lack of interfaces for enhancing acts of interpretations.

Annotations are described as crucial in interpretations and are designated as a killer application (Juola, 2009), scholarly primitive (Unsworth, 2000) and considered as notetaking within main scholarly information activities (Palmer, et al. 2009). Concerning an interpretational act, limitations of annotations are identified (overlapping, flexibility), and there is a demand for customization to the research context and an iterative and agile of schema development (Piez, 2010). Drucker indicates the emergent qualities of interpretation, while suggesting an interface which "supports acts of interpretation rather than simply returning selected results from a pre-existing data set" (Drucker, 2013: 37). In this paper, this desideratum is addressed by designing an interface for collaborative and multi-layered spaces of interpretations based on a semantic graph (Suchman, 2007; Drucker, 2011; Rheinberger, 2010; Barad, 2003).

A specific style of interpretation is chosen as a case study, i.e. collaborative analysis of face-to-face situations in small groups by creating a multiple layered space of interpretation - Objective Hermeneutics. In German-speaking countries, the approach of Objective Hermeneutics is one of the main methodologies used for qualitative analysis (Flick, 2005), which generates deep-structure analyses of cases by reconstructing actions and meanings. Creation of an interface that enables semantic annotations for these acts of interpretations makes it possible to elaborate and explicate a multiple layered space of interpretation.

In the following, we describe settings in the interpretational act of Objective Hermeneutics. Furthermore, the background of the design is outlined in relation to methods, design and data. The main contribution is twofold: (i) realization of an interface focusing the semantic enhancement of the collaborative spaces of interpretation and accountability and (ii) examines the semantic explication of the research data (interactional protocols), the interlinked multiple layered annotations and the possibility to retrace the space of interpretation.

The collaborative interpretational act of Objective Hermeneutics

The theoretical framework of Objective Hermeneutics is based on Oervermann's theory of professionalization (see Reichertz, 2004), whereby the act of interpretation follows strict principles for analyzing 'natural protocols' of social practices (transcripts). In a sequential multi-step procedure of interpretation, the structure of the case is reconstructed. The act of interpretation is realized in small groups where a common space of imagination is created collaboratively, wherein multiple layers of interpretations interfere and make use of falsification and abduction (Flick, 2005). Accordingly, the process of interpretation can be outlined as follows: 1) Specifying research question and analytical framework; 2) choosing appropriate transcript; 3) selecting sequence from interaction protocol (transcript); 4) creating and discussing step by step multiple corresponding stories, perspectives, and connections of the sequence; 5) recontextualisation to the concrete case, whereby in the long run hypotheses of the structure of the case are created iteratively and new sequences are selected (back to 3.). Additionally, 6) a proofing process is started (falsification). Based on this interpretative act, a detailed case structure is created which describes the conflicting motivations, interests and interactions of the actors. While in recent years special research data archives for archiving and re-using the transcripts (non-processable PDFs) have been established, the act of interpretation itself is still paper-based. This situation provides the opportunity for an appropriate case study for designing an interface for collaborative and multi-layered spaces of interpretations (for example, see the archive for pedagogical casuistry (ApaeK) archiving transcripts of classroom interactions)

Methods, design, and data

The research environment for Objective Hermeneutics is based on a participatory design and agile development approach, using Semantic MediaWiki framework. To fulfill the case-related special research requirements an extension for Semantic MediaWiki and a research ontology were collaboratively developed. Besides the analysis of needs and requirements (site visit, artefact analysis) rapid prototyping was used and three versions of the environment were thoroughly tested (the logfile analysis between the last two versions indicates a clear improvement at the interpretation process by reducing the break up rate from 33% to 0%.) A group of distributed researchers across Germany and interested in classroom interactions (topic othering) used the environment in practice over several months and supported the design process by attending meetings and giving feedback.

Interfacing collaborative spaces of interpretations and accountability

Explicating interaction protocols semantically

The act of interpretation in Objective Hermeneutics is based on 'natural protocols' of social practice, which pursue strict notation guidelines for the transcription process (e.g. anonymization, settings of actors, properties like loudness). The transcript is enriched with contextual metadata (e.g. collecting context, duration, and topic). Line by line, each speech act of an actor and relevant interactions are described in detail (based on audio recordings, maps, photographs). This initial base already allows for semantically enhancing the space of interpretation: Interlinking relevant documents, entities, properties, and relations for semantic browsing (Figure 1, 1+2). Additionally, a formula semantically (Figure 1, 3+4) outlines the interactions of the transcript in detail (actor, speech act/interaction, line number). Thus, each annotation of interpretation can be related to this empirical level and the process of interpretation can be retraced. Based on this semantically enhanced transcript, the researchers choose and define their sequence of interest to start their act of interpretation (segment selection).

Figure 1. Metadata of transcript (1, 2) and semantic interactions (3, 4)

Interlinking spaces of interpretation and multiple layered annotations

The act of interpretation in Objective Hermeneutics is semantically-enhanced and explicated by following guidelines for interpretation, whereby the flexibility of interpretation and the computer-mediated co-presence is taken into account. Each selected sequence of the transcript opens up the space of interpretation through multiple layered styles of annotations (stories, perspectives, connections, and contextualization) (Figure 2, 2+3). Subject to their discussions and notes, the researchers specify their arguments and elaborate a common ground for the case analysis. For an adequate interface of the phenomenon, the multiple layered styles of annotations need to be visualized in relation to the corresponding sequence of the transcript (compare Figure 2, 1+3). Closure respectively densification of the space of interpretation is semantically enhanced by creating specific case hypotheses. Researchers create connections between the layered annotations and specific case hypotheses, whereby a hypothesis and its related entities (e.g. layer of annotation, sequence, interaction, actor, or author) can be browsed semantically, described with texts and data representations. Each annotation is described with further relevant properties (e.g. timestamp, researcher name, related sequence) and interlinked within the sematic graph.

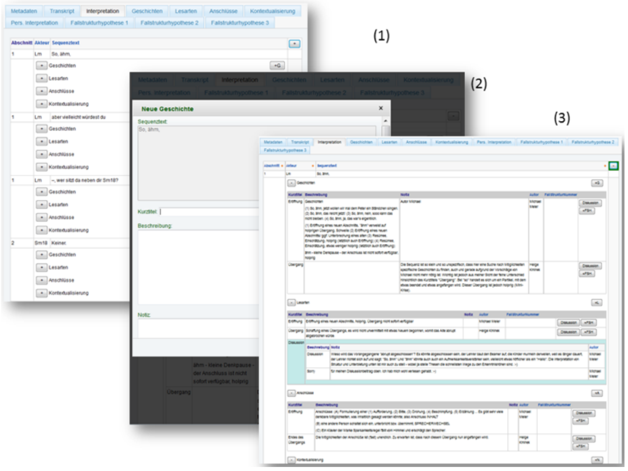

Figure 2. Selected sequences (1), annotation creation (2), and multiple layered annotations and discussions (3)

Retracing the spaces of interpretation and accountability

The analysis and reflection of the research process as well as the spaces of interpretation are enhanced by using a semantic graph and explicating the interaction protocols (transcripts) offering new capacities for retracing the spaces of interpretations (Figure 3). The multiple layered semantic graph interlinks the acts of interpretation and facilitates multiple perspectives for accountability concerning the 1) interaction protocols and their interlinking (Figure 4, 2), 2) the chronological acts of the researchers, 3) the multiple layered annotations for interpretations (Figure 4, 1), and 4) the creation and interlinking of the case hypothesis. Besides these imminent possibilities of the research project, external aspects of accountability can be addressed. While in Humanities the practice of data citations is not widely spread, research communities in Object Hermeneutics have established a citation practice via the archives of the transcripts, referring to the interactions of the transcript in their publications (as bibliographic data). In retracing the spaces of interpretation, the relevant multiple layers of annotations as well as the hypothesis interlinking can be referenced, opened, and described with semantic vocabularies. The semantic graph has been mapped to relevant semantic vocabularies e.g. Wf4Ever Research Object Model (ro), Object Reuse and Exchange (ore), Named Graphs (rdfg), Web Annotation Data Model.

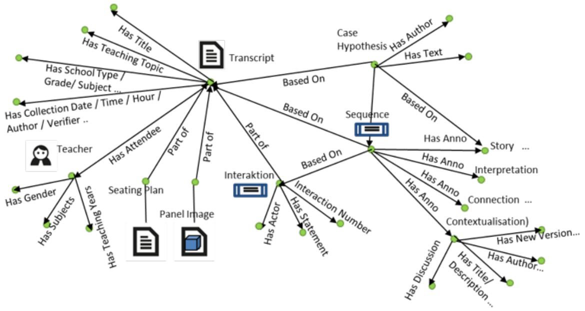

Figure 3. Visualization of semantic graph with traceable entities

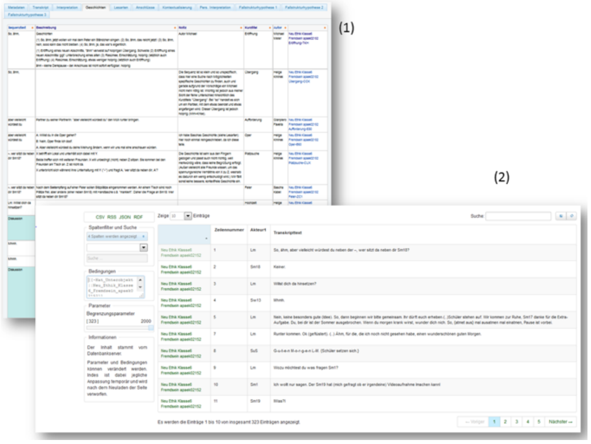

Figure 4. Annotation layer of stories (1) and interactive datatable of interactions (2)

Discussion and outlook

In this paper, we discussed and demonstrated the design of an interface for collaborative and multi-layered spaces of interpretation, using the methodological approach of ‘Objective Hermeneutics’ as a case study. The interface is considered in relation to the phenomenon and the relevant performative material-discursive capacities for the interpretational act, focusing on the use of a semantic graph. The detailed semantic description of the research data (transcripts) and the associated spaces of interpretations (stories, perspectives, connections, and contextualisations along with hypothesis) enable a collaborative and distributed analysis and new ways of retracing the spaces of interpretation (interlinked data, chronological acts, multiple layered annotations, case hypothesis). But time and effort of the semantic enhancement need to be balanced against these added values in each new research project (e.g. interlinking, accountability, data manipulation, visualisation, citation, and openness).

Acknowledgements

We would like to thank the research groups in Objectiv Hermeneutics and Semantic CorA, especially Marc Rittberger, Michael Meier and Sascha Kabel. Initially, the realization of the research environment Semantic CorA was supported by the German Research Foundation (DFG); its further development for Objective Hermeneutics was funded in the context of the eHumanities Center CEDIFOR by the German Federal Ministry of Education and Research (BMBF) no. 01UG1416C.

Letters of 1916 is Ireland’s first digital public humanities project. Launched in 2013, it has become one of the key corpora in providing new insights and understandings of the 1916 period. The project collects and transcribes through crowdsourcing epistolary documents from October 1915 to November 1916 with the goal of creating a window onto a year in the life of the nation. In the middle of the project’s collection period is the Easter Rising (24-29 April 1916), arguably one of the most important events in Irish history as it sets in motion Irish independence from Great Britain in 1921.

The year 1916 was chosen not only because of the centrality of the Easter Rising, but because of Irish participation in the Great War and the historical significance for this throughout the following century in the construction of Irish identity. The collection also reestablishes the role of women in their participation in the Great War as well as the Rising and its aftermath. In addition, epistolary documents were chosen as a record of the everyday and the quotidian, providing a window onto a social history that has too often been repressed or ignored.

With a collection of over 3,500 letters contributed by 54 families and 32 institutions (with new letters being added continually) the corpus is too large to read in its entirety. While search and browse functionality in the project’s ‘Explore’ Database allows users to restrict results to more manageable subsets, the complexity of the letter form, with its frequently meandering content, makes many letters difficult to categorise using a tightly restricted set of keywords. Full text searching also misses many possible letters of interest on a particular topic due to the broad register and idiosyncratic use of language utilised by a wide variety of correspondents (Altman, 88).

A solution to these issues has been to explore the use of alternative methods of analysis and discovery, including topic modelling, vector space modelling with t-SNE vector reduction, and semantic network analysis. These methods provide alternative ways to explore a corpus of this size: too large to be read in its entirety via close reading, yet not big enough to qualify as big data. Rather, this type of collection, not out of reach of many DH projects, might be typified as one of the middle distance in which visualisations can serve as a series of lenses through which areas of interest can be identified for further research.

Topic modelling, although computationally expensive and requiring pre-processing, provides a detailed overview of the corpus and its themes. It highlights the complexity and variety of the letters’ content, as well as suggesting areas for further analysis. Combining the full text of the letters with the editorially-assigned keywords has proved a powerful combination in providing a bird’s-eye view of the corpus by theme.

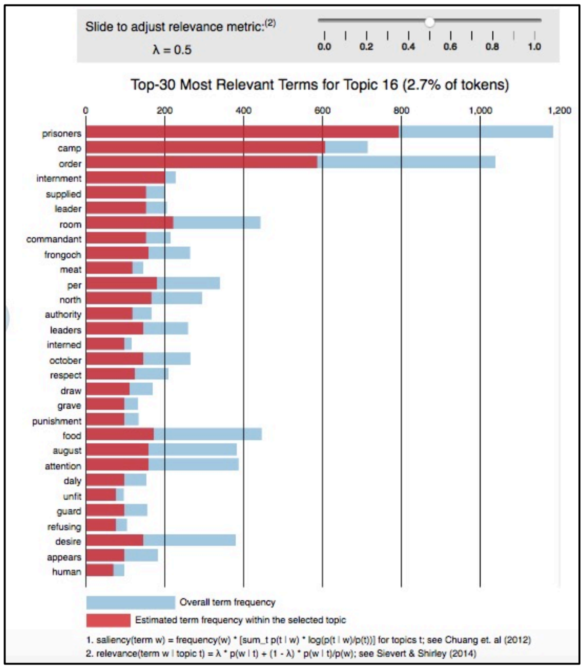

Figure 1. Murder at Portobello Barracks

Figures 1 and 2 show topics 14 and 16 from a model where only the standard stopwords were removed. Topic 14 relates to the murder of Sheehy Skeffington, while Topic 16 focuses on internment. The visualisation was created using 'LDAvis', where the most distinct terms in the topic can be viewed by adjusting the relevance metric λ to 0.5.

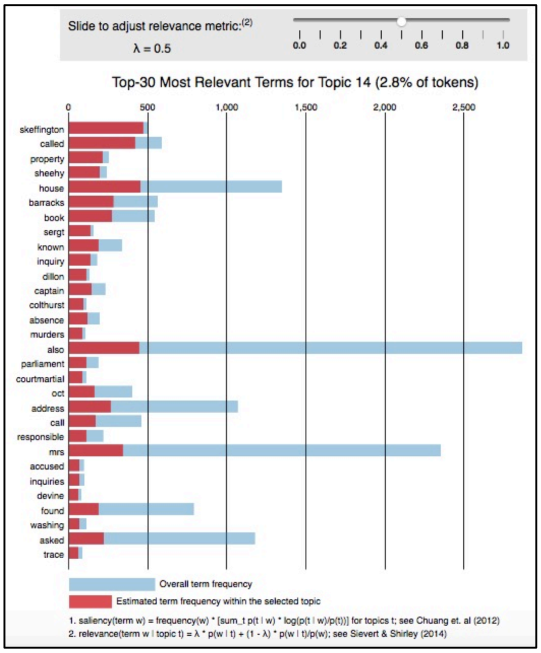

Figure 2. Topic 16 - Internment at Frongoch

Vector space modelling, using the R package 'wordVectors' (Schmidt and Li) which is based on the 'word2vec' algorithm (Mikolov et al.), is effective for a corpus where the researcher is familiar with the broad topics and wishes to zone in on specific aspects. Rather than asking 'which topics are in this corpus?', it allows the researcher to ask 'what does the corpus tell us about this topic?', revealing syntactic and semantic relationships. This type of analysis requires less pre-processing than topic modelling and does not exclude words with a low frequency.

The resulting vector space model can be interrogated, for example by extracting the words nearest to the word vector. For example, the vector for 'rising' (eg the Irish Rising) results in: 'outbreak', 'scene', 'leaders', 'theatre', and 'hostility'. While we may expect the term 'theatre' to refer to a theatre of war, close reading of the six references to 'theatre' in the letters reveals that two refer to an operating theatre while the remaining four are regarding theatre as a place of entertainment. Vector rejection can be used to exclude particular word meanings in cases of polysemy, thus allowing the researcher to specify which meaning they wish to search for. In the above example a researcher interested in entertainment could exclude the alternative meanings by rejecting those words which are related to theatre in the sense of 'hospital' and 'operation'. This would create a vector with the meaning 'theatre as a place of entertainment' enabling a more focused search.

The words nearest the desired search term can be visualised through vector space reduction to two dimensions. We use the Barnes-Hut implementation of t-SNE (t-distributed stochastic neighbour embedding). The visualisation of the 500 words nearest to the vector for 'rising' includes a cluster of words: 'portobello', 'murders', 'accused', 'colthurst' and 'dickson'. This refers to the murders of Sheehy Skeffington, Dickson and MacIntyre at Portobello Barracks on the orders of British officer Bowen-Colthurst.

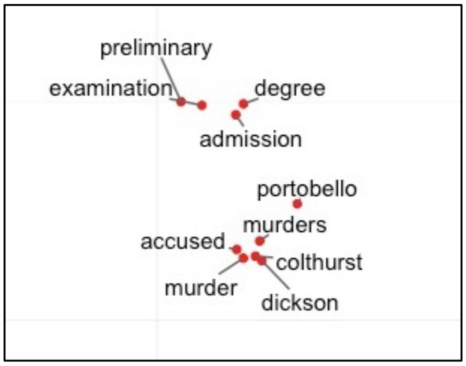

Figure 3. The 'Portobello' cluster

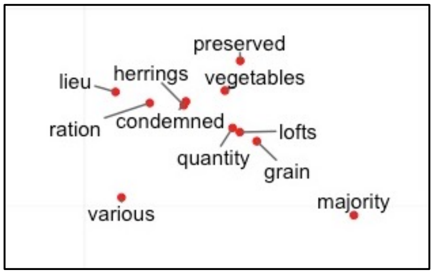

Figure 4. The 'herrings' cluster

A second cluster containing the words ‘herrings’, ‘condemned’ and ‘ration’ is less clear. A key word in context analysis demonstrates one of the strengths of the vector space model, the word ‘herrings’ only appears seven times in the corpus, but it sheds significant light onto the lives of those in internment. Figure 5 illustrates that the first five references to ‘‘herrings’ is in the context of the poor quality of rations provided to the Irish prisoners in Frongoch, a prisoner of war camp where some 3500 Irish men were sent after the British put down the Rising.

	file	position	left	keyword	right
1	L1916_1596.txt	317	the 19th august last salt	herrings	have been supplied to us
2	L1916_1596.txt	329	dinner of fridays but these	herrings	have been very imperfectly cured
3	L1916_1596.txt	391	do not intend taking these	herrings	from the military as doing
4	L1916_1599.txt	52	to refuse the ration of	herrings	as indicated in the second

7	L1916_258.txt	633	consisted chiefly of sardines preserved	herrings	with tom ato sauce and

Figure 5. 'herrings' Key Word in Context

A third analysis builds upon the vector space model by creating a semantic network based on the cosine similarity of terms. The network is visualised using the ‘visNetwork’ R package (Almende and Thieurmel) which can be viewed as an interactive HTML file. This analysis enables the exploration of multiple dimensions of the model. Here terms can be clustered and connected with other terms providing a more detailed representation of the semantic space. This network can suggest a broader and more nuanced range of themes. Each of the analyses, and associated visualisations, provide a transformation of the text, disrupting expectations and providing new avenues for exploration (Clement).

These visualisations are, however, but the first step down the path of the third way. In order to engage the parahippocampal area of the brain, which is responsible for drawing context and meaning, we seek to create a more immersive experience for the reader (Bouchard et al). Thus a layer of interactivity is being explored to enhance these visualisations. While the visualisations themselves provide interesting insights into the corpus, they are, much like a traditional search and browse, rather static implementations in that they are pre-selected and curated. The project is thus exploring how users can be provided with the ability to customise these visualisations through the “slicing” of additional metadata in order to draw comparisons that may not be readily apparent.

However, this type of interactivity is not without its drawbacks. Both topic modelling and vector space visualisations require significant processing power in order to generate the base visualisations and the demands on internal memory of the processing machine are high as a result. Thus, creating these types of visualisations in an “on demand” environment is not feasible without a hardware investment that is beyond the reach of most of DH projects. Thus other options—such as caching, indexing, NoSQL databases, or various other data-related optimisation techniques—must be used in order to develop technical solutions that allow for interactivity while supporting a relatively low cost hardware solution.

These visualisations have begun to offer tantalising new insights into the corpus, providing a third way beyond search and browse. This paper will explore both the visualisations themselves, their strengths and weaknesses within the context of a corpus of the middle distance, as well as the novel readings they enable. The paper will conclude by discussing how interactive visualisations such as these can augment traditional modalities of interaction through a rich toolset for research and exploration.

Introduction

Bernoulli-Euler Online (BEOL) is an interdisciplinary research project funded by the Swiss National Science Foundation focusing on the mathematics influenced by the Bernoulli dynasty and Leonhard Euler. It is being carried out by the Bernoulli Euler Centre and the Digital Humanities Lab at the University of Basel. Its main goal is the integration of different edition projects relating to the Bernoullis and Leonhard Euler into *one* target platform, offering appropriate functionality for researchers interested in the history of science.

The methodological efforts will also be applicable to other editions since they are developed in a generic way. BEOL is based on Knora, a generic infrastructure for humanities data.

Goal of the BEOL–platform and its technical basis

BEOL aims at integrating three edition projects, that are currently all technically different and thus incompatible with one another:

- *Basler Edition der Bernoulli-Briefwechsel* (BEBB): BEBB is an online edition that is based on the MediaWiki software and hosted by the University Library of Basel. It is connected to the library's metadata catalogue for manuscripts (Basler Inventar der Bernoulli-Briefwechsel). The letters are encoded in Wiki markup and are converted to HTML to represent them on the web. The mathematical formulae are encoded in LaTeX.
- *Leonhardi Euleri Opera Omnia* (LEOO): LEOO is a printed edition of the works of Leonhard Euler that was begun in the early 20th century. In the context of BEOL, the volume containing Euler's correspondence with Christian Goldbach (Euler 2015) will be integrated as a proof of concept. This volume has been prepared using LaTeX (as well as the volume with Euler's correspondence with Daniel Bernoulli that has been published recently). We expect to be able to integrate all the other recent volumes set in LaTeX in a similar manner. For the older volumes, the printed books would have to be scanned (including OCR) and marked up.
- Jacob (I) Bernoulli's scientific notebook *Meditationes*: The manuscript is held in the university library of Basel (shelfmark L Ia 3, 367 pages) and has already been digitized. The manuscript consisting of 287 entries is being transcribed at the Bernoulli Euler Centre using XML (The XML format is specified closely to the TEI specifications P5, so it can be transformed quite easily to TEI/XML) for the text and LaTeX for the mathematical notation that is embedded in the XML.

The three edition projects do not only overlap thematically, but also in terms of the persons involved (authors, mentioned persons) and bibliographical items (literature referred to in the texts, references in-between the editions' texts). Letters exchanged between members of the Bernoulli dynasty, Leonhard Euler and contemporary mathematicians and scientists are an important part of these edition projects and thus it is desirable to identify and match the persons in all editions in order to display their relations.

The technical basis for BEOL is Knora, an infrastructure for humanities data (Rosenthaler and others 2015) consisting of an RDF-triplestore, an OWL base ontology, and a RESTful API that allows for querying and adding to the data. The base ontology (see prefix 'Knora' in Figure 1) defines common value types (such as a calendar independent format to represent dates using the Julian Day Number) used among humanities projects and can be further extended in project specific ontologies. BEOL will provide such an ontology (see prefix 'BEOL' in Figure 1), defining its own resource classes and properties needed to represent the edition projects' texts and entities. Wherever possible, existing ontologies will be reused by making subclasses and subproperties. BEOL is part of the NIE-INE project, which aims to create a general-purpose infrastructure for digital editions, using Knora as its technical foundation. A focus of this project will be abstracting out concepts shared by different projects and formalising them as ontologies.

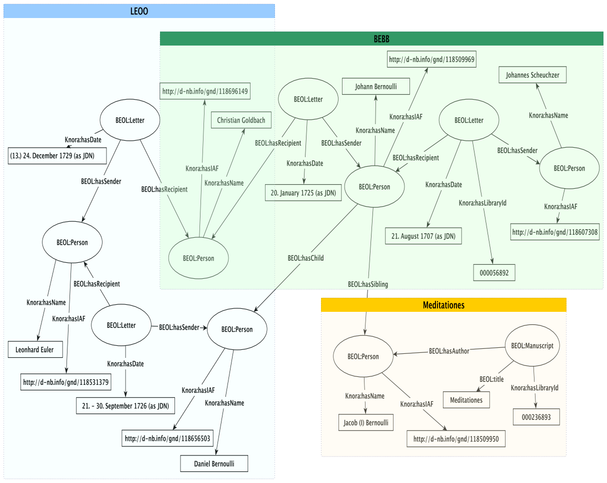

Figure 1: BEOL network and its components

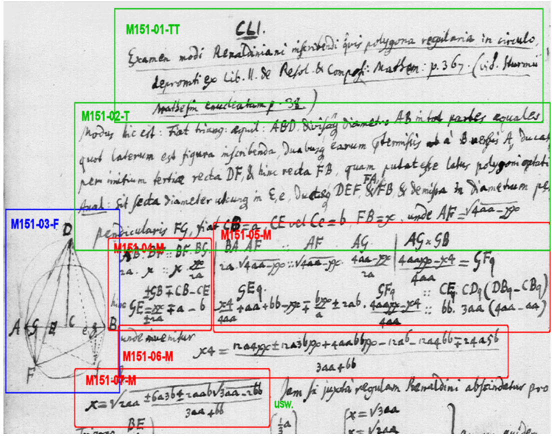
Figure 1 represents all relations between persons (We refer to the Integrated Authority File (GND), and in order to represent locations, we will also refer to GeoNames), letters, and manuscripts (we also link to the catalogue of the Basel university library that keeps many of the original copies of the letters and manuscripts of BEOL), as well as their properties as directed graphs. For reasons of clarity, we use a simplified model here. The coloured rectangles indicate that these have been imported from different edition projects which – considered in isolation – do not allow for this kind of overview. Moreover, indices and bibliographies have to be unified on the BEOL platform (e.g., Christian Goldbach occurs both in BEBB and LEOO). The BEOL platform will be connected to Early Modern Letters Online, so it will be interoperable with other edition projects.

Importing editions to the same target environment

In order to represent all three editions in the same target environment, they have to be homogenised first. We decided to do so using an XML-based approach. This has the additional advantage that we can make both the texts of BEBB and LEOO available as TEI/XML to the outside world quite easily by applying XSL transformations. We can also use the same routine to import the editions into BEOL. Knora converts XML-encoded texts to RDF in order to store them in the triplestore. From RDF, an XML document can be recreated that is equivalent to the one originally imported. A mapping defines the relations between XML elements and attributes and the entities defined in the ontology.

- BEBB Wiki markup can be transformed to XML using a MediaWiki parser. Wiki tags and structures are mapped to XML tags, and references to other letters, bibliographical items, and images (facsimiles of the letters) can be handled. Once the letters are available on the BEOL platform, the old URLs will have to be forwarded.
- The Goldbach-volume of LEOO is set in LaTeX and can be converted to XML using LaTeXML. Additional mappings to the available standard functionality and customisations can be provided using Perl scripts. LaTeXML provides a MathML conversion for mathematical formulae.
- The Meditationes are transcribed in an XML-based format (see LaTeXML). Derived texts of these files can be generated using XSL-transformations. In this way, several layers (diplomatic, normalized) of the text can be produced. Our approach addresses segments defined on the facsimile (see Figure 2) and turns them into a reading text step by step. The figures (see segment 'M151-03-F' in Figure 2) will be extracted by applying a combination of various image processing techniques and redrawn as vector graphics.



M151-01-TT
M151-02-T
M151-03-F
M151-04-M
M151-05-M
M151-06-M
M151-07-M
usw.

Figure 2. Part of Meditatio 151

One of the main challenges in the BEOL project is the faithful representation of mathematical notation and its relation to the surrounding text (see Figure 2) using web technologies. At the moment, we are using MathJax (which accepts both LaTeX and MathML as input formats) to render the mathematical formulae in the web browser. We also consider MathML as an option, although not all web browsers fully support MathML.

We are aiming at developing a browser based user interface that will be based on the Angular 2 framework (although in the meantime, we are already using Knora's current interface, SALSAH) that not only makes it possible to present the texts on the web and to offer search functionality, but also to add to the data (sufficient permissions provided). The users may create their own annotations on the BEOL platform. Basically, the user interface interacts with the Knora API in order to create new resources, manipulate properties etc. Since BEOL is based on Knora, all of its generic functionality can be used for this purpose.

Conclusion

BEOL integrates three different edition projects into one platform and allows researchers to query previously separated contents and add to them. The specific problems posed by the combination of text and mathematical notation can be addressed in a generic manner. All the functionality to be developed will be part of Knora and can be reused by other projects dealing with scientific texts from mathematics and physics.

Introduction

In previous articles (di Lenardo et al, 2016; Seguin et al, 2016), we explored how efficient visual search engines operating not on the basis of textual metadata but directly through visual queries, could fundamentally change the navigation in large databases of work of arts. In the present work, we extended our search engine in order to be able to search not only for global similarity between paintings, but also for matching details. This feature is of crucial importance for retrieving the visual genealogy of a painting, as it is often the case that one composition simply reuses a few elements of other works. For instance, some workshops of the 16th century had repertoires of specific characters (a peasant smoking a pipe, a couple of dancing, etc.) and anatomical parts (head poses, hands, etc.) ,that they reused in many compositions (van den Brink, 2001; Tagliaferro et al, 2009). In some cases it is possible to track the circulation of these visual patterns over long spatial and temporal migrations, as they are progressively copied by several generations of painters. Identifying these links permits to reconstruct the production context of a painting, and the connections between workshops and artists. In addition, it permits a fine-grained study of taste evolution in the history of collections, following specific motives successfully reused in a large number of paintings.

Tracking these graphical replicators is challenging as they can vary in texture and medium. For instance, a particular character or a head pose of a painting may have been copied from a drawing, an engraving or a tapestry. It is therefore important that the search for matching details still detects visual reuse even across such different media and styles. In the rest of the paper, we describe the matching method and discuss some results obtained using this approach.

Method

Matching patterns in a bank of images is a problem that has been extensively studied in the Computer Vision community as « Visual instance retrieval » (Sivic and Zisserman, 2003). The definition of the task is : *given a region of a query image, can we identify matching regions in other images of a large iconographic collection* ?

Historically, the most successful methods were based on feature point descriptors (like SIFT, see Lowe, 2004) used in a Bag-of-Words (Jegou et al, 2008) fashion. The global architecture can be summarized as follows:

For each image in the collection:

- Extract the feature points for the image.
- Quantize the point descriptors to a Visual-Bag-of-Words representation.

Given a query region:

- Use the Bag-of-Words signatures to rank the first N most likely candidates of the collection.
- For each candidate, re-rank them according to a spatial verification of the matching points with the query region.

In practice, such an approach works extremely well and numerous improvements (Shen et al, 2009; Crowley and Zisserman, 2014) have been brought over the years to the different steps of the procedure. Hence it is still considered state of the art for the traditional datasets which focus on building and object retrieval in photographs.

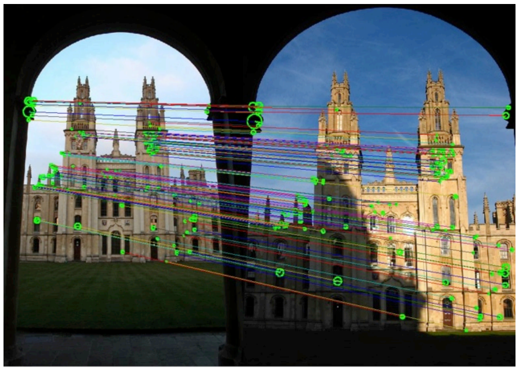

Figure 1: Working Bag-of-Words matching for buildings.

However, it was shown recently (Seguin et al, 2016; Crowley and Zisserman, 2014) that such approaches break completely when not dealing with the same physical objects and important style variations like we do in paintings. An example can be seen on Figure 2.

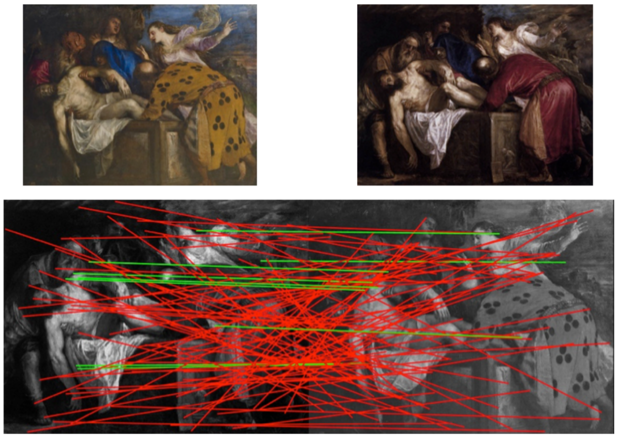

Figure 2: Feature point matching breaks when local features and style vary.

More recently, Convolutional Neural Networks (CNN) have had tremendous success in almost all areas of Computer Vision (object detection, recognition, segmentation, face identification, etc.) and CNN have established themselves over the last couple of years as an extremely powerful tool for almost any vision based problem.

A CNN is a multi-layer architecture where each layer transforms its input according to some parameters (also called weights). What makes them so powerful is that all these parameters can be learned « end-to-end » (for example in the case of object classification, just with images and their corresponding labels).

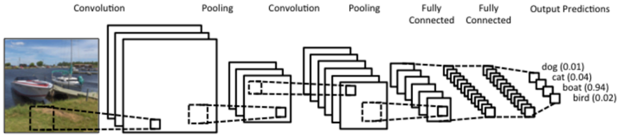

Figure 3: Simplified structure of a Convolutional Neural Network.

It has been shown in Donahue et al (2014) that CNN pre-trained on very large datasets, like Deng et al (2009), for object classification tasks offer a very good abstract representation of the image information, and are thus applicable for other vision problems. They generalize much better when transferring from photographs to paintings, contrary to the traditional Bag-of-Words techniques (Seguin et al, 2016; Crowley and Zisserman, 2014). However, its application to visual instance retrieval was always hindered by the fact that they traditionally output a single global descriptor for the image, hence not directly allowing for region (sub-image) retrieval (Babenko et al, 2014).

In Razavian et al (2014), the authors proposed to just precompute the CNN descriptors for some subdivision of the image. However, such approach limits the possible granularity of the windows, and multiply the memory requirement by a huge factor.

Another more promising approach introduced in Tolias et al (2015) is to work directly on the CNN feature maps. More precisely, a common way of extracting a CNN descriptor for image retrieval is to take an image of size *(H, W, 3)* (height of *H* pixels, width of *W* pixels and 3 color channels RGB) go through all the convolutional layers of CNN, which outputs the *feature maps* : a structure of size *(H', W', F)* (*F* channels of size *H'* and *W'*). From these feature maps, taking the sum (or the max) of each channel gives a signature of size F which is (after normalization) the descriptor of the image.

Traditionally, the network used is the VGG16 (Simonyan and Zisserman, 2014) architecture which given an image of size *(H, W, 3)* creates feature maps of size *(H/32, W/32, 512).*

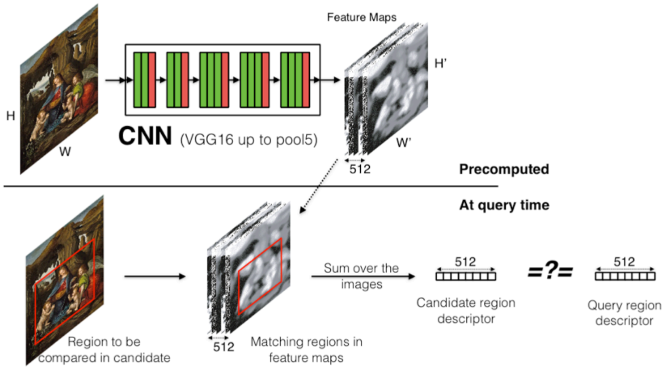

Figure 4: Region evaluation architecture.

Now, starting from the feature maps, computing the signature of a sub-part of an image is already easier, we just need to compute the sum of the corresponding region in the feature maps to obtain the descriptor of size *F*. However, evaluating many different regions would still be prohibitive from a computation point of view.

In order to alleviate the performance problem, Tolias et al (2015) proposed to use *integral images*. Given an image *I*, the integral image $I_\int$ is $I_\int(y,x) = \sum_{i<x,j<y} I(j,i)$. This allow for extremely quick computation of the sum of an image for a given area (y_1, y_2, x_1, x_2) (Fig.5) :

$$\sum_{x_1 \leq i < x_2, y_1 \leq j < y_2} I(j,i) = I_\int(y_2,x_2) + I_\int(y_1,x_1) - I_\int(y_1,x_2) - I_\int(y_2,x_1)$$

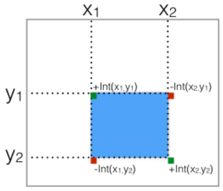

Figure 5: Integral images

This trick allows for extensive evaluation for the best matching window for the query image in the target collection. The global procedure for searching is the following, quite close to the Bag-of-Word approach:

For each image in the collection:

- Extract the feature maps of the image, and compute the corresponding integral images.
- Compute the global signature (with the whole image as window).

Given a query region:

- Use the global signatures to rank the first N most likely candidates of the collection.
- For each candidate, re-rank them according to an extensive look of the sub-windows in the images using their pre-computed integral images.

In order to greatly improve the results, we add the following improvements:

- The parameters of the network we use were fine-tuned using the Replica dataset (Seguin et al, 2016) (image retrieval in paintings). This dramatically improves the system resilience to color and style.
- We use Spatial Pooling according to Razavian et al (2014) which consists of extracting 4 blocks per evaluated region instead of 1. It makes the search roughly 4 times slower but allow for much better retrieval of complex patterns by directly encoding spatiality.

Results

The following experiment was run on the whole Web Gallery of Art collection (38'000 elements). Each image was resized so that its smaller dimension is 512 pixels, and the integral images of the feature maps computed on it. Given a query region for an image, the 300 most likely candidates are extracted from the WGA collection, and re-ranked according to the best matching window on each of them. Using 35 cores on a server machine, the complete request takes less than 4 seconds.

Examples of queries and their results are shown on Figure 6. In query 1 and 2, the starting image is Leonardo da Vinci's *Virgine delle Rocce* (Paris, Louvres), first version of this subject (1483-1486). Leornado is an interesting case study and his influence in Europe is known to be extremely important for the general compositions of paintings, character typologies and landscape patterns. In query 1, the group of Mary, the angel and the two children is selected. The first result is the version of the same subject (London, National Gallery) finished a decade after the Paris version, with the contribute of Ambrogio de Predis. The painting is different in color but has the same composition. The second and third results are other versions of the same subject by unidentified painters of the XVIth century. This constitutes typical examples of the propagation of a complex theme.

In query 2, only a detail from the landscape is chosen. Interestingly, the second result is a painting from Bernardino de Conti, which is a variation on the same theme, reusing the landscape but without the angel and with the two children kissing.

For query 3, we use a painting by Marco d'Oggiono, a follower of Leonardo, very similar to the one by de Conti and we select only the two children kissing. Results 1 and 3 feature paintings where only the children are present, showing that this replicator has an autonomy of its own. The third result by Joos van Cleve confirms the historical migration of this subject, as autonomous, from Italy to Flanders.

These 3 simple queries illustrate how the detail matching method can easily unveil the transmission network between different series of paintings.

Perspectives

The search of matching details in large-scale databases of paintings may enable to find undocumented links and therefore new historical connections between paintings. By tracking the propagation and transformations of a replicator, it becomes possible to follow the evolution through time of repertoires of forms and view each painting as a temporary vehicle playing the role of an intermediary node in a long history of images transmissions. Although in continuation with traditional methods in Art History, such a tool opens the avenue for research at a much larger scale, searching for patterns and finding new links simultaneously in millions of digitized paintings.

Introduction

When access as a value of scholarship is foregrounded in publishing, libraries emerge as "natural and efficient loci for scholarly publication" (Courant and Jones, 2015). In a rapidly evolving digital publishing landscape, academic libraries are poised to address scholars' publishing concerns about gaining access to opportunities for support and re-skilling, providing open access to their intellectual content, and ensuring access to the audiences who will most benefit from their work. The growth of library-based publishing services is evidenced by the 115 college and university libraries currently listed in the Library Publishing Directory (Lippincott, 2016). This paper presents selected results from a US-based survey on the needs of humanities scholars in a contemporary publishing environment, emphasizing aspects of the survey responses that shed light on the question of access in publishing from three perspectives: access to support services, access to content, and access to audience.

About PWW

Publishing Without Walls (PWW) is a Mellon-funded initiative at the University of Illinois led by the University Library in partnership with the School of Information Sciences, the department of African American Studies, and the Illinois Program for Research in the Humanities. Our project is developing an innovative and experimental library-based digital scholarly publishing model that aims to be accessible, scalable, and sustainable. Our objective is to develop a model for library-based publishing services that can be adopted broadly by other academic libraries to address scholars' emerging needs in a contemporary publishing environment. The model itself places humanities scholar at the center of the ecosystem, with services informed by—and responsive to—scholars' needs. Research and development within the project are strategically designed to address known gaps within the current landscape: the gap between what and how scholars want to publish and what existing systems of print publishing can accommodate; the gap between the everyday practices of humanities scholars and what high-level tools exist for producing and supporting digital scholarship; and the gap between digital scholarship and publishing opportunities at resource-rich institutions and Historically Black Colleges and Universities (HBCUs).

Survey Method

This paper presents the selected results of a large-scale survey about scholars' publishing practices and perceived needs. The full survey aims to understand what and how scholars want to publish, when and why they choose to publish digitally, and how they perceive the success of their digital publications. Survey outcomes will directly inform the development of PWW's shareable service model, but we also anticipate that our survey results will be relevant to digital humanists and other scholars engaged in digital scholarly publishing, whether such efforts are located within or beyond an academic library.

From June to October 2016, we conducted a large-scale survey of scholars, especially targeted at humanities scholars and scholars at HBCUs in the United States. The survey was developed by the PWW Research Team in spring 2016, and comprised around 30 questions. The survey covers six broad themes: respondents' experiences with print and digital publishing; respondents' publishing objectives; publishing tools and platforms; publishing services and support; publishing from the scholars' perspective of reader as opposed to author; and general attitudes toward print and digital publishing. The survey was distributed through listservs and social media venues targeting scholars in the humanities generally as well as selected niche communities to encourage sufficient responses across disciplines and institutions. The survey received 250 responses.

The team used the Qualtrics platform to present the survey and conduct initial analysis, with further quantitative data analysis in SPSS. Preliminary findings have been reported previously (Fenlon et al., 2016), and analysis is ongoing. The survey instrument and a summary report will also be archived in the IDEALS repository (Velez et al., in preparation).

Results

Respondents were asked to identify which aspects of publishing posed the most significant challenges with respect to their experiences with print and digital content. Figure 1 represents the percentage of respondents who indicated each potential issue as either "quite challenging" or "extremely challenging" in print or digital publishing.

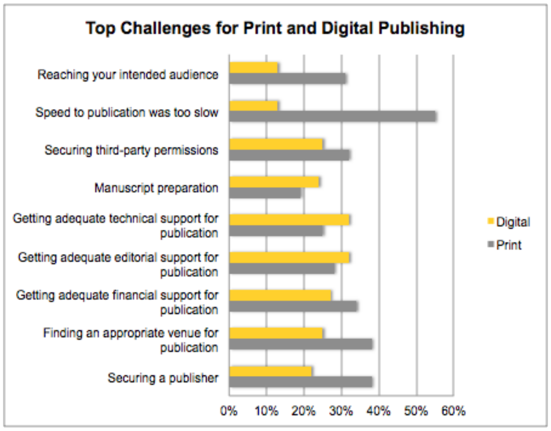

Figure 1. Top Challenges for Print and Digital Publishing

The top three challenges for digital publishing include getting adequate technical, editorial, and financial support for publication. Respondents were also asked to indicate and rank their top five publishing goals, which are illustrated in Figure 2 as a weighted bar graph where a first-place ranking is assigned 10 points, a second-place ranking is assigned 5 points, and a third-place ranking is assigned 1 point. The top three goals are consistent with the traditional expectations for scholarly publishing: contributing new information to one's field, encouraging and participating in dialogue about an area of study, and establishing a formal record of one's scholarship.

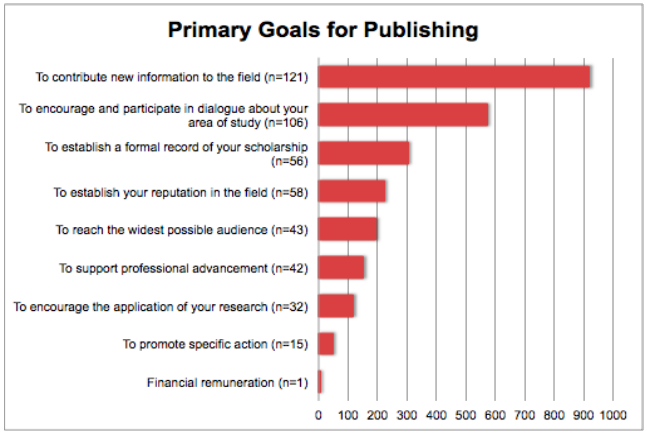

Figure 2. Primary Goals for Publishing

Figure 3 illustrates the top three audiences that scholars indicated they most wish to reach. The top two audiences relate to peers within the academic community. While interest in reaching the general educated reader and students is less frequently cited, it is sufficiently robust to consider how reaching these audiences may have an impact on scholars' decision making with regard to the medium they choose and the venues they seek for publication. Understanding how less traditional, but still prevalent, publishing goals affect these choices is also a potentially fruitful avenue for exploring how explicitly stated publishing objectives inform, and possibly shift, priorities regarding representation and dissemination within scholarly publishing. These themes are explored in a set of four charts in Figure 4.

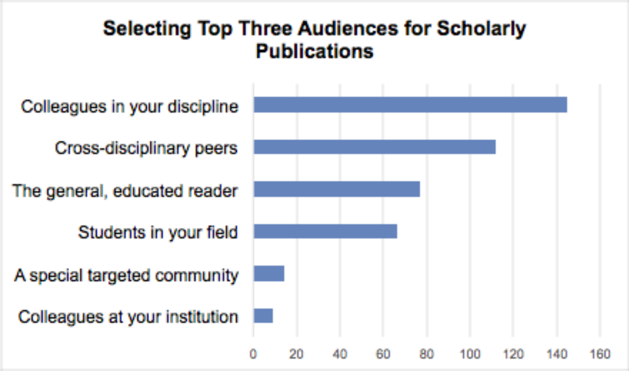

Figure 3. Selecting Top Three Audiences for Scholarly Publications

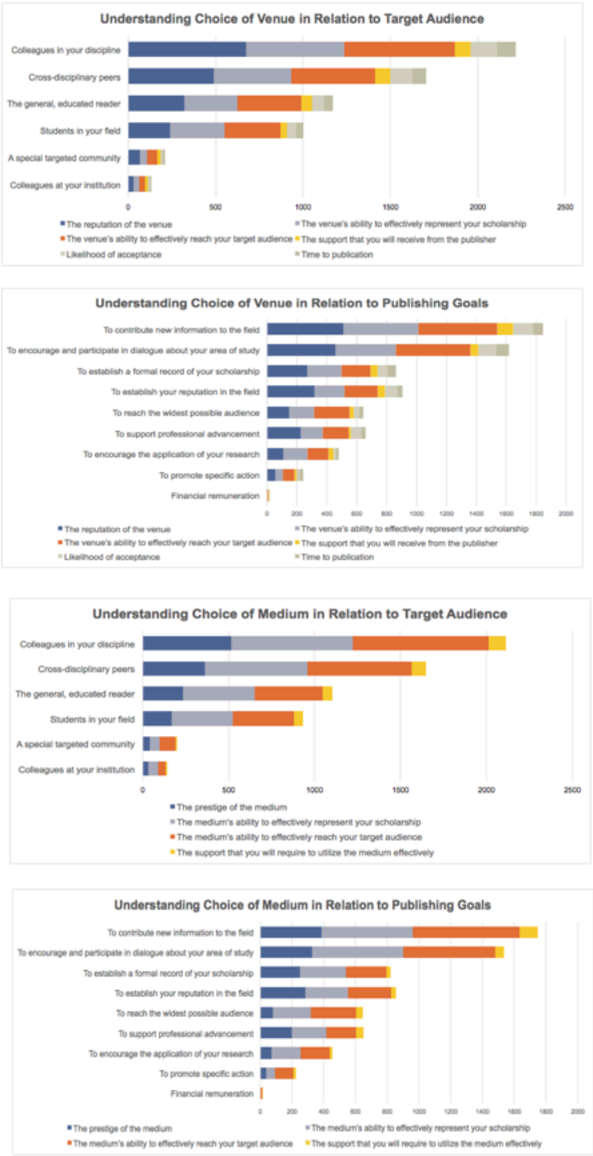

Figure 4. Comparing Scholars Selection Criteria for Publishing Medium and Venue in Relation to Target Audience and Publishing Goals

Discussion

When comparing scholars' characterization of challenges in digital versus print publishing, speed to publication and reaching one's intended audience emerge as the two greatest challenges to print publication, but they are perceived as relatively less challenging in digital formats. This difference between print and digital suggests that these "challenges" might be considered the primary "affordances" that scholars perceive for digital publishing. For digital publishing, the top three challenges that scholars face all relate to receiving adequate support for the logistical aspects of the process, including technical, editorial, and financial support. Though not one of the top three challenges, another aspect of publication that the survey responses suggest is more challenging in digital than print publication is manuscript preparation. Despite the fact that the most prevalent challenges to digital publishing relate to issues of support, the support that scholars will receive from publishers never emerges as a major factor in a scholar's choice of publishing medium or venue, regardless of their specific publication goals and intended audiences.

The top three considerations with respect to choosing both one's medium and the venue in which to publish are the ability to effectively represent the scholarship, the ability to reach one's target audience, and the reputation or prestige of the venue or medium. The weight of these and remaining factors, however, shifts when analyzed in conjunction with scholar's goals and target audiences, suggesting opportunities for developing more nuanced consultative support services when selecting tools and platforms in light of scholars' goals and intended audience. For digital publishing, the first two considerations (representation and audience) are likely to be the determining factor in a scholar's decision to shift away from traditional print publishing and to consider library-based digital publishing opportunities. The emphasis on reputation and prestige, however, may prove problematic for fledgling initiatives that seek to develop alternatives to the established publication models of university presses. Further research will investigate what constitutes acceptable markers of prestige to determine the importance of affiliation with an institution of higher education, which libraries already have, or affiliation with known university presses, which most libraries do not have.

Conclusion

Compared to other publishing models, situating support for scholarly communication in the research library creates possibilities for addressing challenges related to access and sustainability of digital scholarly publishing. This support can be performed efficiently as a part of library activities, leveraging pre-existing technical infrastructure that is designed to support discovery and preservation as well as digital scholarships programs within scholars' commons. These aspects of library-based publishing prove especially compelling in light of survey findings that the biggest challenges for digital publishing include securing adequate technical support services, in addition to financial and editorial support.

The Publishing Without Walls initiative is seeking to offer attractive solutions for authors 1) whose scholarship is not sufficiently represented in the print medium and 2) who place a high value on the technological affordances provided by open access digital scholarship to reach their intended audiences. We further anticipate that developing value-added support services in the form of individual consultations and incubation workshops will help ease the support-related challenges cited by scholars, particularly when assessing which platforms and tools will best represent an author's scholarship.

Introduction

When an earthquake struck Nepal in 2015, the band One Direction sent tweets encouraging their fans to donate to relief efforts, while an Indian activist tweeted accusations of Christian missionaries trading conversions for aid. While Twitter users were quick to bring their own agendas to the Nepal earthquake, does the same hold true for earthquakes in other parts of the world? A series of earthquakes that struck Kumamoto, Japan, and then Muisne, Ecuador in 2016 attracted a substantial amount of Twitter attention as well, yet as far as we are aware, the One Direction fans and the Indian activist made no comment. These users are onlookers to all three earthquakes: in other words, they are not directly affected by these events, but they tweet about them.

This paper explores onlookers' responses across three different earthquakes: the 2015 Nepal earthquake, and the nearly-simultaneous earthquakes in Kumamoto and Ecuador in 2016, which we treat as a single event. This present work expands on our previous conclusion that onlookers tend to bring their own agendas to disasters. This paper shows that users who tweeted about the Kumamoto and Ecuador earthquakes were generally more interested in the earthquake or the affected areas than their own agendas, as their interest in the earthquake could not be predicted by interests in other topics.

Background

A substantial amount of research has explored how social media causes users to engage with political, social, and humanitarian problems; however, opinions on social media's effectiveness—whether it causes users to donate money or participate in campaigns—are mixed. Some argue that displaying concern in social media is more about acquiring social capital than effecting change (Shulman; Gladwell; Morozov, The Net Delusion; Morozov, To Save Everything, Click Here), while a Pew Research Center survey finds that social media does create change (Raine, Purcell, and Smith). One analysis found that charities' use of social media does not increase donations (Malcolm), while another finds that certain tweeting strategies do (Gasso Climent) although tweets may not raise awareness about the charity's causes (Bravo and Hoffman-Goetz). All these studies concur that social media enable substantial discourse about crises. The question we explore here is how much of this conversation is predicted by a user's preexisting interests, and how this varies even among the same type of event in different areas.

Methodology

We followed a similar data collection process for both Nepal and the Kumamoto and Ecuadorean earthquakes: we sampled data from Twitter's REST API to attain a broad sample of onlookers. For Nepal, we had gathered a dataset of tweets sent during the three weeks following the Nepal earthquake by searching for any tweets that mentioned the word "Nepal" from April 24, 2015 to May 8, 2015. We then randomly selected 15,000 users from this set and harvested all tweets they sent between April 24, 2014 and May 8, 2015. We attempted to capture only English-speaking users to increase the likelihood that we would capture users not directly affected by the earthquake, but we still found some users who tweeted in multiple languages. This left roughly 11,000 onlookers for Nepal. For Kumamoto and Ecuador, we gathered a dataset of tweets sent in the two weeks following the Kumamoto earthquake that mentioned "Kumamoto" or "earthquake." We randomly selected 30,000 users and harvested every tweet they sent between March 16 and May 16, 2016. We collected more users, but fewer tweets for each user, than we did in the Nepal dataset so as to look for users who displayed a broader set of interests. This left around 25,000 onlookers in Kumamoto and Ecuador. We were able to filter out non-English tweets much more effectively in the latter dataset than the Nepal dataset.

For the tweets for each event, we made a bipartite graph of users to words, and performed community detection using a method proposed by Okamoto and Qiu (2015) [2], which allows for overlapping communities. Okamoto and Qui's method takes a single parameter, alpha, which controls the resolution of community detection: the smaller its magnitude, the larger the number of detected communities. We set alpha to 0.001 in both cases. The output of this method was a list of each node (users and words), and a percentage ranking rating its affinity with each community. We used these results to generate a list of top words in each community, which told us what users who tweeted about that community were interested in. From this process, a number of topics emerged, which we labelled manually according to our interpretations of the top words in each.

Since this method also gave us a ranking for users' affinities to each community, it allowed us to examine the influence of other topics on a user's likelihood to tweet about either event. We wanted to examine how much a user's propensity to tweet about other topics predicted the probability that he or she would tweet about topics related to the earthquake. We ran multivariate linear regressions on each topic in the dataset using the Python sklearn module (Pedregosa et al.). We ran one regression for each topic, in which we treated a user's propensity to tweet about the topic under consideration as a dependent variable predicted by his or her propensity to tweet about other topics.

Results

Our analysis demonstrated a certain predictive power for some topics in each dataset. Applying this process to the Nepal tweets produced 17 topics about a variety of concerns, from entertainment to world events. Table 1 shows these topics. Two of them, topics 5 and 15, treat the earthquake directly.

A correlation exists between tweeting about entertainment topics and tweeting about the earthquake. Tweeting about topic 15 predicts that a user will tweet about topic 2, which is about pop music: the top words include "fifth," "harmony," "video," and "Justin." This correlation is the strongest in the dataset; few other topics show nearly as much correlation. Consequently, we observe a degree of correlation between tweeting about entertainment topics and tweeting about the disaster in Nepal. While the more targeted topics, like the One Direction topic, do not show much correlation with other topics, the more general entertainment topic does.

Table 1: Topics for Nepal, showing probability of tweeting about one topic (X-axis) given likelihood of tweeting about other topics (Y-axis)

In summary, we observe correlation between tweeting about entertainment topics and tweeting about the Nepal earthquake. Those who bring other agendas such as an interest in a particular musical group to the disaster tend to tweet mostly about those topics.

Does the same hold true for Kumamoto and Ecuador? Table 2 shows a few topics from the Kumamoto and Ecuador earthquakes. Our analysis demonstrates that an onlooker's propensity to tweet about some topics could be predicted by interest in others. For example, a user who tweeted about news topics, such as U.S. politics (specifically, topic 43) or Asian news (topic 4), was likely to tweet about Nigerian politics (topic 2). Likewise, a user who tweeted about Japanese Entertainment (37) was also likely to tweet about other entertainment topics.

Table 2: Topics for Kumamoto and Ecuador, showing probability of tweeting about one topic (X-axis) given likelihood of tweeting about other topics (Y-axis) (truncated for space)

On the other hand, no such correlation was observed in the opposite direction: no topic predicted a user's tendency to tweet about topics 6 and 22, the earthquake topics. All coefficients in those regressions were under 0.01. The two topics that focus on Kumamoto are relatively closed: users who tweet most about the Kumamoto earthquake tweet about little else during this period.

Our interpretation is that users who tweeted about Kumamoto or Ecuador were specifically interested in earthquakes, Japanese culture, or the affected regions. The majority of users who tweeted about the Kumamoto and Ecuador earthquake topics were interested in specialized topics relevant to the events: they were not, for example, One Direction fans. We therefore conclude that while some users tweeting about Kumamoto and Ecuador were motivated by general interests in news or entertainment, they were a much smaller group than in the Nepal dataset.

Conclusions

We find that while users often brought their own agendas to tweeting about Nepal, fewer did so when tweeting about Ecuador and Japan. Users who tweeted about Kumamoto and Ecuador tended to focus on topics related to the earthquakes, and less on issues that the earthquakes might demonstrate.

Our future work will test these conclusions with other earthquakes. In particular, we will examine the 2011 Tohoku Earthquake which raised serious political issues. Additionally, in our present work, we treat the Kumamoto and Ecuador earthquakes as a single event because distinct "Kumamoto" and "Ecuador" topics did not emerge from our text mining, which itself is suggestive of how Twitter users understood them. In our future work, we will probe more deeply for differences between the two earthquakes.

Placing Segregation

Robert Shepard
robert-shepard@uiowa.edu
University of Iowa Libraries, United States of America

Residential segregation and socioeconomic inequality among neighborhoods is common in many American cities. Many large American cities became modern industrial urban places during the mid- to late-nineteenth century, so it is critical to understand the reality of human dimensions in cities during this period. Popular narratives tracing the history of the phenomenon back to that time have been constructed from analyses that used city wards or other large unit areas that aggregate data for many hundreds or even thousands of families. For example, prominent works like *American Apartheid* have concluded that black Americans were not particularly segregated from whites before 1900, and even then they were only slightly more separated from the native white population as the Irish and German immigrants (Massey and Denton 1993). By relying on aggregate datasets from the past, urban historians have been missing out on a level of granularity that would provide better measurements of segregation as well as critical context of spatial separation, given the relative smallness of American cities during their earlier years.

Mid-nineteenth century U.S. Census records contained an abundance of potential information relating to socioeconomic realities of each home during this key formative period in American history. The 1860 and 1870 censuses were especially unique in that they collected each individual's personal estate value and real estate value (these economic variables were omitted from subsequent censuses). However, American census takers did not record address numbers of those they visited before 1880, which was after the Bureau of the Census stopped collecting these critical economic data about individuals and households. Furthermore, even if address data were available on manuscript census records for the time period, much of the built environment has changed since the mid nineteenth century, including the complete renaming of roads and – most importantly – the renumbering of houses along the street grid.

Rather than using easily-available aggregate data collected at city ward levels to make inferences about past urban geographies, this work has combined city directories and period advertisements with census records to reconstruct digitally the historical address systems of cities and geolocate every possible family in the 1860 census for the cities of Washington, D.C., Nashville, Tennessee, and, for the 1870 census, the city of Omaha, Nebraska (additional cities will be added as the project expands). Notably, Donald DeBats and Mark Lethbridge had pioneered a similarly intensive approach for the much smaller cities of Newport, Kentucky and Alexandria, Virginia (DeBats and Lethbridge 2005). Because of the extensive details collected by these censuses, these geolocated individuals provide rich new datasets for historical researchers to explore. By geolocating individuals, this research also highlights specific individual living situations and helps to complement known (and more easily accessible) anecdotal accounts from common primary sources such as journals and letters.

Placing Segregation is the primary result of this research effort - a new, open access digital project at the University of Iowa Libraries' Digital Scholarship and Publishing Studio that explores research questions about housing segregation and socioeconomic disparities across nineteenth century American cities through a series of fully interactive maps and scholarly interpretations derived from the geolocated census data. This presentation introduces core functionality of the digital exhibit and also explains in detail the process of developing the data and the website.

Built primarily upon Leaflet.js, an open-source JavaScript library for mobile friendly interactive maps, as well as other openly available JavaScript libraries such as Fuse.js, this digital map exhibit gives public audiences direct access to detailed census data for the years 1860 and 1870 in these select U.S. cities. A search feature allows visitors to quickly locate the historical residences of persons of interest and read complete census information about them, while a number of simple layer filters permit users to explore potentially infinite topics by giving them direct control over the geographic data. The primary digital exhibit gives audiences without GIS experience the power to ask research questions in a spatial environment.

Initial research findings from the project indicate that urban historians have been substantially underestimating the degree of housing segregation experienced by free black residents, even though some past research built on ward-level analyses closely approximated the extent of housing segregation between the native white population and various immigrant groups. The data generated for this project illustrate American cities were in fact significantly divided according to social class and wealth, long before the rise of the automobile. However, residents were less divided by wealth differences than they were separated spatially by skin color in Washington D.C. or by German and Irish origin in Nashville and Omaha.

Character-distinguishing features in fictional dialogue: the case of *War and Peace*

Daniil Skorinkin
skorinkin.danil@gmail.com
National Research University
Higher School of Economics, Russia

Introduction

The study of character speech is a topic of fairly consistent interest among digital literary scholars. It is usually acknowledged that voices of characters are essentially different from narrator's own voice and should be treated separately. Some researchers have fictional dialogue removed from the texts they studied before any tools of computational investigation are applied (Hoover, 2004). Quite a lot of effort has been made recently to address the problem of identifying character speech in prose and attributing it to the correct speaker (ссылки!). One of the outcomes of such research is the possibility to study voices of different characters on relatively large scale and apply computational tools that measure their recurring stylistic parameters.

Method

The study of character speech has traditionally had strong ties to the fields of stylometry and authorship attribution, as their methods proved quite useful for studying idiolect of a fictional speaker. Suffice it to say that one of the seminal works in stylometry, Computation into criticism# by Burrows (Burrows, 1987), was focused on the study of character speech in Jane Austen's novels. The method developed by Burrows grew into what is currently known as Delta, a widely-adopted standard for authorship attribution. Delta has been consistently and successfully applied to identifying the author of an unattributed text of different languages and genres, but at the same time it saw considerable usage as a purely stylometric tool for the study of text where authorship is undisputed. Among other things, this included research into the specific idiolects of fictional characters (see, for example, Rybicki, 2006).

In our research Delta was used as one of the two possible approaches to studying character voices in Leo Tolstoy's War and peace. Much like in case of Senkewic (Rybicki, 2006), there's certain critical opinion (Eikhenbaum, 2009) that Tolstoy's characters are quite distinct from each other in their speech. Our own experience of carefully reading speech instances extracted from War and peace (for details on extraction procedure see (Skorinkin, Bonch-Osmolovskaya, 2015) supports the opinion. So it seemed natural to try and test computational methods that already showed their applicability to precisely such task. We used R package stylo by (Eder *et al,* 2013)

Testing the method on Russian material

Surprisingly enough, we were unable to find any work that applied Delta to any Russian material. Therefore we felt obliged to conduct a couple of experiments that would test its general applicability to Russian before we proceed with character speech. At the first stage we tried Delta's ability to distinguish between Tolstoy and Dostoevsky. The training set contained one of the six parts of Dostoyevsky's Crime and Punishment and three of the fifteen books of Tolstoy's War and Peace. The remaining 18 pieces of text (5 by Dostoevsky and 13 by Tolstoy) constituted the test set. The results with different settings can be seen in Table 1 and Figures 1,2:

N most frequent	Words	Character 3-grams	Character 3-grams	Character 3-grams
25	80% (4/5)	60% (3/5)	60% (3/5)	100% (5/5)
30	80% (4/5)	80% (4/5)	60% (3/5)	80% (4/5)
35	80% (4/5)	60% (3/5)	60% (3/5)	80% (4/5)
40	80% (4/5)	60% (3/5)	60% (3/5)	80% (4/5)
45	80% (4/5)	60% (3/5)	80% (4/5)	100% (5/5)
50	80% (4/5)	60% (3/5)	80% (4/5)	100% (5/5)
55	80% (4/5)	60% (3/5)	80% (4/5)	80% (4/5)
60	100% (5/5)	60% (3/5)	80% (4/5)	80% (4/5)
65	100% (5/5)	60% (3/5)	80% (4/5)	80% (4/5)
70	80% (4/5)	60% (3/5)	80% (4/5)	100% (5/5)
75	80% (4/5)	80% (4/5)	80% (4/5)	80% (4/5)
80	80% (4/5)	60% (3/5)	80% (4/5)	100% (5/5)
85	80% (4/5)	80% (4/5)	80% (4/5)	100% (5/5)
90	100% (5/5)	80% (4/5)	80% (4/5)	100% (5/5)
95	80% (4/5)	80% (4/5)	80% (4/5)	100% (5/5)
100	80% (4/5)	80% (4/5)	80% (4/5)	100% (5/5)

Table 1. Delta authorship attribution, Tolstoy vs Dostoevsky

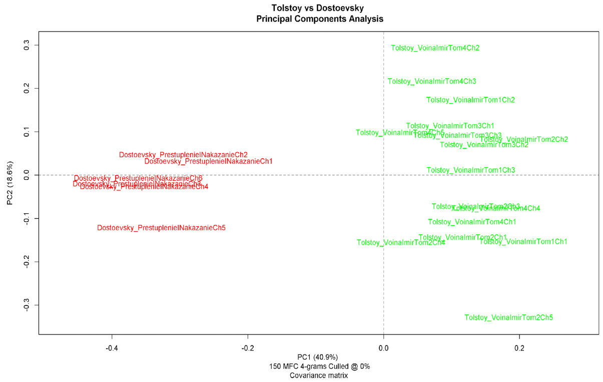

Fig. 1. Delta PCA on 150 most frequent character 4-grams, Tolstoy vs Dostoevsky

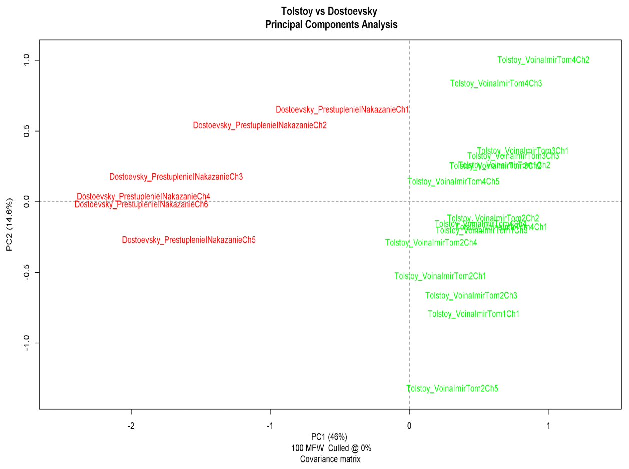

Fig. 2. Delta PCA on 100 most frequent words, Tolstoy vs Dostoevsky

The second experiment involved four Russian authors Tolstoy, Dostoevsky, Goncharov and Turgenev. All four represent (roughly) the same epoch of Russian literature and all four are recognized as masters of realistic prose. We used three novels by each author for our experiment. At the first stage two out of each three were placed in the training corpus, and Delta was supposed to attribute the remaining one. All four novels from the test corpus were attributed correctly. At the second stage we reverted the experiment and left only one novel by each author in the training set. In this case Delta consistently showed 7 out of 8 correct attributions (the only mistake being Tolstoy's Family Happiness incorrectly attributed to Dostoevsky.A possible explanation could be that Family Hap-piness is written in first person from the point of view of a young woman, something uncommon for Tolstoy; and the only Dostoevsky's work the training corpus contained was The Insulted and Humiliated , also a first-person narrative). Fig. 3 shows Delta scores for all the novels visualized with help of principal component analysis.

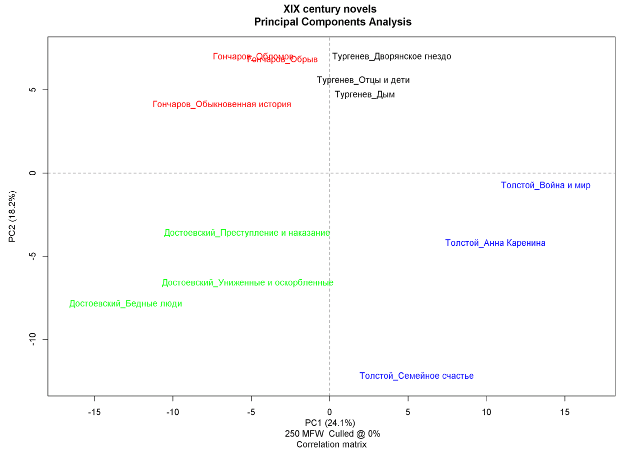

Fig. 3. Delta PCA for 12 Russian novels of 1850-1870-ies, 250 most frequent words

Applying Delta to Tolstoy's characters

Having thus shown that Delta is applicable to Russian, we proceeded with our experiment. In the first place we applied the method to top 5 characters by the total number of speech instances. We split the total sets of speeches by each character and then tried authorship attribution The results are shown in Table 2.

N most frequent	Words	Character 3-grams	Character 3-grams	Character 3-grams
25	80% (4/5)	60% (3/5)	60% (3/5)	100% (5/5)
30	80% (4/5)	80% (4/5)	60% (3/5)	80% (4/5)
35	80% (4/5)	60% (3/5)	60% (3/5)	80% (4/5)
40	80% (4/5)	60% (3/5)	60% (3/5)	80% (4/5)
45	80% (4/5)	60% (3/5)	80% (4/5)	100% (5/5)
50	80% (4/5)	60% (3/5)	80% (4/5)	100% (5/5)
55	80% (4/5)	60% (3/5)	80% (4/5)	80% (4/5)
60	100% (5/5)	60% (3/5)	80% (4/5)	80% (4/5)
65	100% (5/5)	60% (3/5)	80% (4/5)	80% (4/5)
70	80% (4/5)	60% (3/5)	80% (4/5)	100% (5/5)
75	80% (4/5)	80% (4/5)	80% (4/5)	80% (4/5)
80	80% (4/5)	60% (3/5)	80% (4/5)	100% (5/5)
85	80% (4/5)	80% (4/5)	80% (4/5)	100% (5/5)
90	100% (5/5)	80% (4/5)	80% (4/5)	100% (5/5)
95	80% (4/5)	80% (4/5)	80% (4/5)	100% (5/5)
100	80% (4/5)	80% (4/5)	80% (4/5)	100% (5/5)

Table 2.

The most common mistakes are between princess Marya Bolkonskaya and Natasha Rostova and between prince Andrew Bolkonsky and Pierre Bezukhov. Their closeness can be seen in Figure 4:

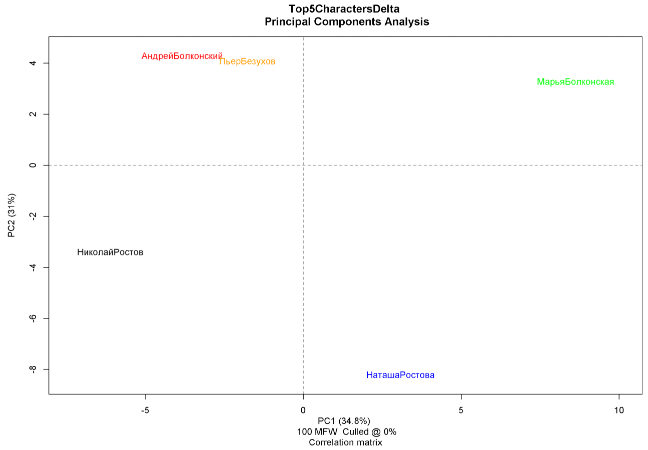

Fig. 4. Delta PCA for top 5 most talkative characters in War and Peace, 100 most frequent words

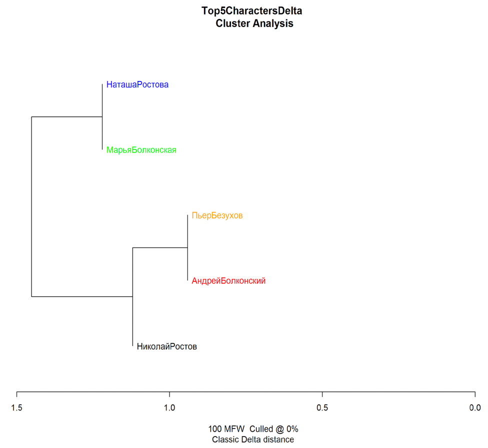

Fig. 5. Delta-based hierarchical clustering for top 5 most talkative characters in War and Peace, 100 most frequent words

The quality of speech authorship attribution inevitably got worse once we expanded our selection from 5 to 15 characters. The results were still quite tolerable reaching 10 out of 15 with certain settings. The analysis of mistakes showed that a) they're less likely to occur between characters of different gender and b) the mistaken characters have quite a lot of mutual conversations.

Further on, we decided to pay more attention to overall Delta scores of character voices and see if they give us any meaningful clustering of characters. Figure 6 shows PCA of characters based on Delta.

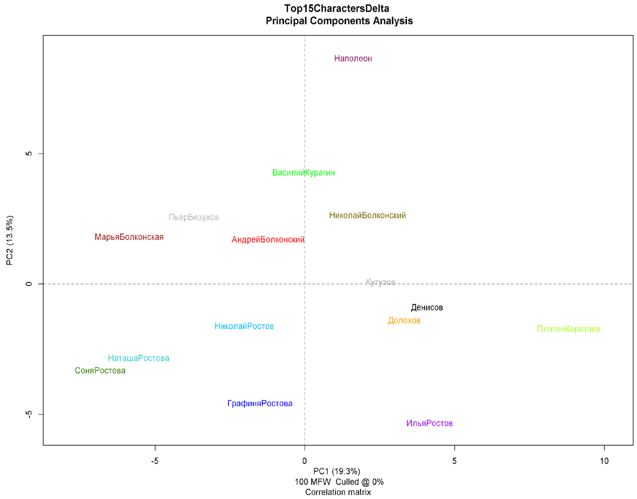

Fig. 6. Delta-based PCA for top 15 most talkative characters in War and Peace, 100 most frequent words

One can easily see the clustering of Rostov family, to a lesser extent this applies to Bolkonsky family as well. Dolokhov, Denisov and Kutuzov could constitute the 'war' cluster.

We then made another expansion and moved from 15 to 30 characters. Figure 7 demonstrates PCA of Delta scores for this selection.

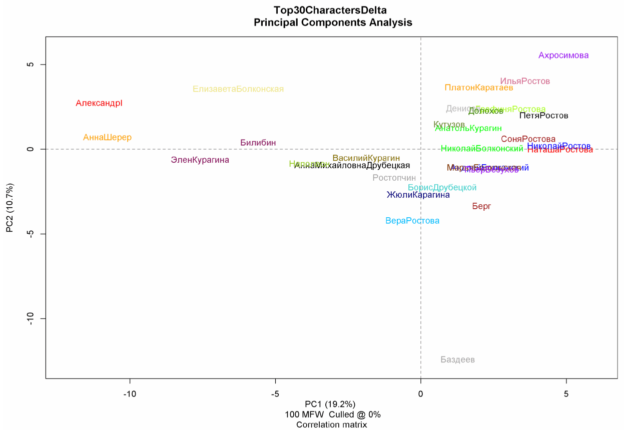

Fig. 7. Delta-based PCA for top 30 most talkative characters in War and Peace, 100 most frequent words

The most striking thing here is the obvious separation of Vera Rostova from the rest of Rostov family. The difference between cold, tempered and rational Vera and her emotional and very sentimental relatives is outspoken and obvious to the reader, but it seems valuable to have this potential quantiative support in the form of different Delta scores. What is even more striking is that Vera is quite close to Berg, a rationalizing careerist who becomes her husband. Note also the closeness of Boris and Julie Karagine, another pragmatic couple happily united in a marriage of convenience.

Applying alternative features

Having tried Delta, we proceeded with our own set of alternative features for character voice analysis (a typical step, as dectibed in Eder, 2015). These features are not related to the lexical makeup of character speech and attempt to reduce the influence of gender-related morphological features of Russian language and the factor of mutual interactions between characters. At this stage we limited ourselves to four features only: the average number of words, the ratio of exclamatory sentences, the ratio oa question sentences and the ratio of punctuation marks (latter being a crude approximation of the 'disruptedness' of speech, which seems rather typical of certain more emotional and lively characters).

When the character set is limited to 5 characters these features even manage to distinguish character speech with some tolerable accuracy (though worse than Delta). However, the analysis of mistakes shows that they capture fundamentally different types of similarities than Delta does. For instance, joyful Natasha in this case is never mistaken for sentimental and melancholic Marya, but rather for her boisterous brother Nikolai. Pierre, on the other hand, is mistaken for Marya rather than for Andrey, who is distinct from them all. Figures 8 and 9 show the results of PCA and hierarchical clustering for these characters based on our own alternative features.

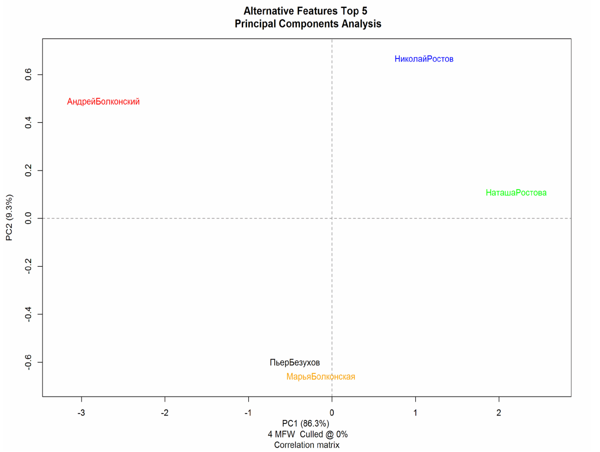

Fig. 8. PCA for top 5 most talkative characters in War and Peace, 4 alternative features

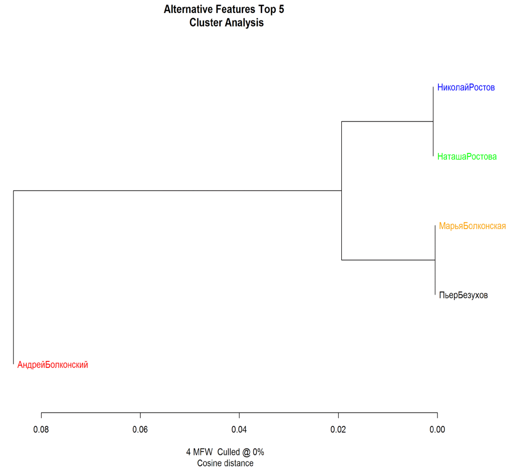

Fig. 9. Hierarchical clustering for top 5 most talkative characters in War and Peace, 4 alternative features

If we compare figures 8 and 9 to their counterparts from the Delta experiment (figures 4 and 5) we can see that the alternative features ignore gender or mutual interactions/ The hypothesis is that they enable us with a more indepth view of a character personality, his/her emotional type and so on.

Figures 10-12 show data on wider selections of characters using alternative features.

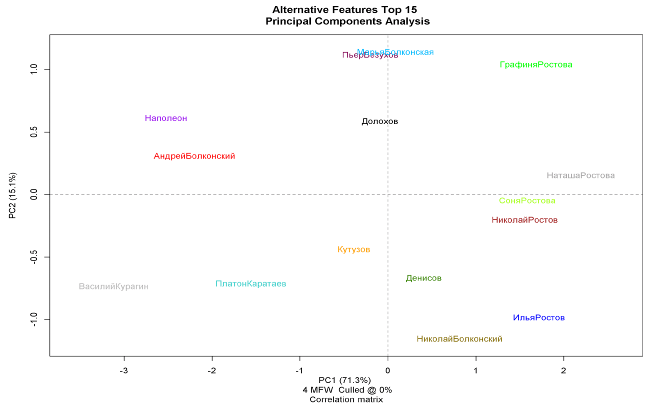

Fig. 10. PCA for top 15 most talkative characters in War and Peace, alternative features

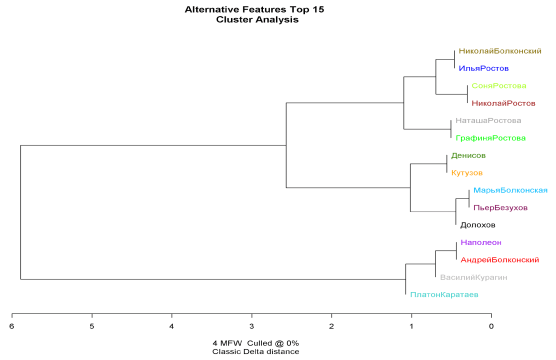

Fig. 11. Hierarchical clustering for top 15 most talkative characters in War and Peace, alternative features

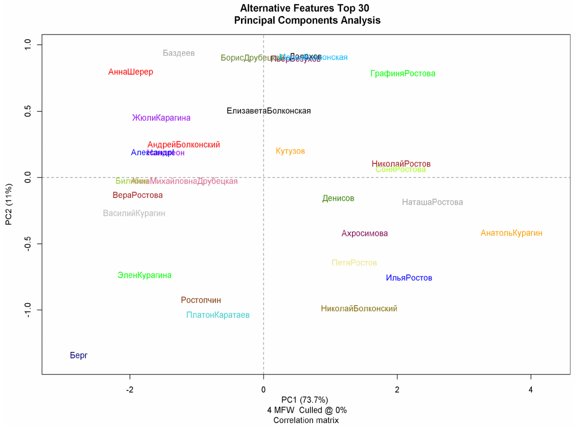
Note that here we do not see any similarity between Andrey and Pierre. Moreover, Andrey is close to Napoleon, which is rather striking given Napoleon is his hero and role model for a considerable part of the novel.



The separation of Vera, on the other hand, is still rather visible - she is far from Moscow-centered Rostov world and close to Saint-Petersburg world of Kuragine family and berg.

Illustrations to Photographs: Using computer vision to analyse news pictures in Dutch newspapers, 1860–1940

Thomas Smits
t.smits@let.ru.nl
Raboud University, The Netherlands

Most digital humanities projects are based on the analysis of text. However, in our increasingly visually orientated world, it has become clear that we should also devise ways to analyse visual material. In the last couple of years, the Royal Library of the Netherlands (KB) has made important steps in this emergent field. Delpher, the interface that provides access to the KB's digital collections, gives users the opportunity to search for images with captions in its database of digitized newspapers. The KBK-1M database, which holds all the images published in the KB's digitized newspapers, provides researchers with the opportunity to analyse the visual material of this collection in a viable way.

In my paper for DH2017 I will present the preliminary results of my researcher-in-residence project at the KB (six months starting May 2017). My project applies a new computer vision technique to sort the images of the KBK-1M database according to the way in which they were reproduced (engraving/half-tone), thus shedding a new light on an important transitional phase in the history of the visual culture of the news.

The visual representation of news events is generally connected to the technological progress of photography (Bardoel and Wijfjes, 2015). The so-called half-tone revolution of the early 1880s, enabling the massive reproduction of photographs in print media, is seen as forming the basis for our current visual news culture. From a media archaeological perspective, several historians of nineteenth-century media have challenged this technocentric narrative (Gitelman and Pingree, 2003). Hill and Schwartz (2015: 3) propose a contingent history of "news pictures" as a separate "class of images," which does not solely focus on photographic technologies, but on the discourse surrounding them. In relation to this theoretical development, several studies have demonstrated that photography was not the first medium used to visually represent the news. From the early 1840s, illustrated newspapers disseminated news pictures on a massive scale and developed a discourse of objectivity, based on eyewitness accounts, which would be adapted and used for photographs later in the century (Keller, 2013; Gervais, 2010; Barnhust and Nerone, 2000; Park, 1999).

If we accept that the perceived objective nature of news pictures is not based on the affordances of a certain technology but on the discourse(s) of objectivity surrounding a specific medium, it follows that the turning point between the use of illustrations and photographs as the preferred medium to visually represent the news is a critical moment in the history of modern visual news culture. Most commonly, Dutch researchers have presented this point as a watershed, located at the publication of the first photograph of a news event in a newspaper (Kester and Kleppe, 2015). However, case studies from a media archaeological perspective suggest a relatively long transitional period in which illustrations and photographs coexisted and competed as authentic, objective visual representations of the news (Keller, 2013; Steinsieck, 2006). It remains unclear precisely when photography achieved its pre-eminence and why this happened: why did newspapers stop using illustrations to represent the news when they had done so for many decades?

The early reliance on case studies to describe the transitional phase is understandable, as in pre-digital times, a distant reading of the large number of images published in newspapers was all but impossible. My project will shed more light on this important debate by analysing news pictures in Dutch newspapers on a large scale. Using the power of the Dutch supercomputer Cartesius, I will apply the technique of a recent project of Fyfe & Ge (2016) to the images in the KBK-1M database. Fyfe set out to study how computer vision and image processing techniques could be adapted for large-scale interpretation of British Victorian illustrated newspapers (Fyfe, 2016). Using MATLAB, Ge devised a method to analyse two so-called low-level features of images: the pixel ratio, the number of low-intensity pixels divided by the total number of pixels, and the entropy level: the amount of information contained in the image. By juxtaposing these two features, they were able to sort the images of the illustrated newspapers according to the technique used for their reproduction. Half-tones, used to reproduce photographs, exhibit both a high pixel ratio and a high entropy level, while engravings, used to reproduce illustrations, display lower pixel ratios and entropy levels (Ge, 2016). Fyfe has shown that this technique can also be used to identify other categories of images. Maps, for example, exhibit lower pixel ratios and entropy levels than detailed illustrations (Fyfe, 2016).

At DH2017 I will present the first results of my project. By analysing the low-level features of images in the KBK-1M database, I will be able to show when Dutch newspapers started to printed both illustrations and photographs on a large scale. In addition, the period when they competed as objective visual representations of the news can be identified. In doing so, my project introduces a digital humanities approach to the relatively theoretical field of nineteenth-century visual culture studies.

Introduction

Many libraries and museums around the world have been releasing their digital collections and making them accessible online. They provide new opportunities for people to acquire information, but they also pose new challenges for accessing these large quantities of humanities resources. Language barriers are one of the main issues for accessing multiple databases in different languages. In this paper, we propose a method to link Ukiyo-e prints between databases in different languages by exploiting semantic similarity of metadata values across languages, in order to achieve our ultimate research goal that aims to provide multilingual access to multiple and diverse databases. We believe our proposed method could assist users in accessing Ukiyo-e databases regardless of languages.

Ukiyo-e, Japanese traditional woodblock print, is known as one of the popular arts of the Edo period (1603–1868). Many libraries, museums and galleries in Western countries have digitalized Ukiyo-e woodblock prints with the metadata values in different languages. Table 1 shows an example of the same Ukiyo-e prints that are exhibited in multiple databases with metadata values in different languages.

Ukiyo-e prints	Metadata values		Language	Database
	Title	Artist		
	凱風快晴	葛飾北斎	Japanese	Edo-Tokyo Museum
	Gaifū kaisei	Katsushika Hokusai	English (Transliteration)	Library of Congress
	South Wind, Clear Sky	Katsushika Hokusai	English	Metropolitan Museum of Art

	Helder weer en een zuidelijke wind	Katsushika Hokusai	Dutch	Rijksmuseum
	Fuji bei schönem Wetter von Süden gesehen	Katsushika Hokusai	German	Bildarchiv Foto Marburg

Table 1. An example of the same Ukiyo-e prints that are exhibited in multiple databases with metadata values in different languages

For linking the same Ukiyo-e prints between databases in different languages, our previous methods (Batjargal et al., 2014; Kimura et al., 2015; Kimura et al., 2016) utilize the metadata values to calculate the similarity between Ukiyo-e prints, in which the metadata values are translated into the same language by using bilingual dictionaries or online machine translation services.

Resig (2013) has developed an image similarity based Ukiyo-e print search system, which is able to search the same Ukiyo-e prints from multiple databases regardless of languages. However, this method cannot be applied to other humanities resources that have no images, such as texts, audio, video and so on.

In this paper, we use the metadata values to calculate the similarity between Ukiyo-e prints, which is the same as our previous methods (Batjargal et al., 2014; Kimura et al., 2015; Kimura et al., 2016). The difference is that we calculate similarity between metadata values of Ukiyo-e prints in different languages without translating.

Methodology

Our method is based on word embeddings (Mikolov et al., 2013a), which are dense, low-dimensional and real-valued vectors for representing words. By using word embeddings, the words with a similar meaning have closer distances in a vector space, which means the semantic relationships between words can be captured. An example is shown in Fig. 1, in which two words “storm” and “hurricane” that express similar concepts are closer in a vector space (only two dimensions are shown for simplicity). Word embeddings can be learned by using the Word2Vec toolkit, which employs a simple neural network model that can be trained on a large amount of unstructured text data in a short time (billions of words in hours).

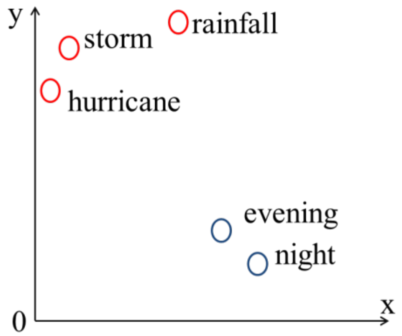

Fig. 1 An example of capturing the sematic relationships between words by using word embeddings

Our proposed method is motivated by the idea of Mikolov et al., (2013b) that the same concepts have similar geometric arrangements across languages. Fig.2 illustrates the vector representations of Japanese words (“雨” and “嵐”) and English words (“rainfall” and “storm”) that are used to describe weather phenomena. It can be seen that the same concepts (e.g. weather phenomena) in Japanese and English have similar geometric arrangements in a vector space.

What is more important is that the relationship between vector spaces that represent these two languages can possibly be captured by learning a mapping between them, e.g. a liner mapping (dotted arrows in Fig.2). If we know some word pairs in Japanese and English, e.g. “雨” and “rainfall”, “嵐” and “storm”, we can learn a mapping that can help us to transform other words in the Japanese vector space to the English vector space.

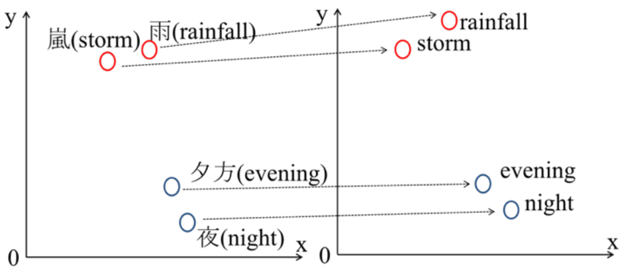

Fig. 2 The vector representations of words that are used to describe weather phenomena (“storm” and “rainfall”) and time (“evening” and “night”) in Japanese (left) and English (right)

Our goal is to measure the similarity between Ukiyo-e prints by using their metadata values in different languages. Motivated by the idea above, we represent textual metadata values as vectors in each language. Then, we learn a mapping between vector spaces that represent two languages in order to transform the vector representations of textual metadata values from source language space to target language space. Once we obtain the vector representations of textual metadata values in target language space, we can calculate the similarity between metadata values in different languages.

Fig. 3 illustrates how our method works. Firstly, we represent the titles of Ukiyo-e prints by additive combination of the vectors of words that compose the titles (Step 1 shown in Fig. 3). And then, we learn the mapping between vector spaces that represent different languages by using some title pairs in Japanese and English (Step 2 shown in Fig. 3), which can help us to transform metadata values from one language space to the other language space.

Fig. 3 An example that illustrates the main tasks of the proposed method

Experiments

We conducted experiments to evaluate our proposed method in linking the same Ukiyo-e prints in Japanese and English.

In the experiments, the titles are used to calculate similarities among Ukiyo-e prints. Based on our method, the Japanese and English titles are represented by additive combination of the vectors of words that compose the titles. We train the Japanese and English word vectors on

Japanese and English Wikipedia articles using Word2Vec toolkit.

In the process of learning the mapping between two language spaces, we use 600 Japanese-English parallel short sentence pairs for pre-training the mapping between Japanese and English vector spaces. In order to make this mapping more suitable to Ukiyo-e titles, we further use 74 pairs of Japanese and English Ukiyo-e titles to optimize this mapping, in which each pair of titles refers to the same Ukiyo-e prints. This optimized mapping are used to transform other vectors of the titles in Japanese space to English space.

We calculate the similarities between the titles of Ukiyo-e prints using cosine similarity. For each Japanese title, after we obtain the mapped vector in English space, our method outputs the most similar English title vector as its corresponding English title.

We use 173 pairs of Japanese and English Ukiyo-e titles as the test data to evaluate our method. The precision at top-n are used to measure the experimental results, which means the percentage of Japanese titles whose truly corresponding English title are ranked in top n. In order to verify the effectiveness of using Ukiyo-e titles to optimize the mapping, we show the results of both conditions of using Ukiyo-e titles and without using them in the pre-training. The experimental results are shown in Table 2.

	Precision in top-1	Precision within top-5	Precision within top-10	Precision within top-15
Without using Ukiyo-e titles	2.3%	12.2%	17.4%	22.7%
Using Ukiyo-e titles	29.1%	41.9%	50.0%	54.7%

Table 2. The experimental results

These results show that the precisions are further improved by using Japanese and English Ukiyo-e titles to optimize the mapping between Japanese and English vector spaces. The experimental results also confirm the usefulness of our proposed method for linking the same Ukiyo-e prints in Japanese and English.

Conclusion

Our proposed method measures the similarity between metadata values without using any bilingual dictionary or online machine translation system. Moreover, our proposed method represents the metadata values using word embeddings, which can capture the semantic relationships between metadata values.

In the future, we will evaluate our method for linking Ukiyo-e prints in other languages.

It can be challenging to be a solo digital humanist, given the range of skills required, deficits in training, and the need for software, hardware and technical support. As E.E. Snyder points out, researchers may be using digital methods but not consider themselves "digital humanists," and thus exist outside of virtual networks like Twitter and conferences like Digital Humanities (2012). Even as colleges and universities recognize the potential of digital humanities, they often struggle to support and sustain DH projects. Digital humanities centers, like many cutting-edge, interdisciplinary academic programs and centers, are fragile, subject to changing priorities and budget cuts (Sample 2010). Moreover, DH centers may not necessarily be able to support the range of researchers' interests and needs. In any case, many digital humanists work at institutions without a DH center, so they often lack institutional support and immediate colleagues whom they can learn from and with. Sample describes the common situation of the DH scholars who lack centers: "We'll never be able to turn to colleagues who routinely navigate grant applications and budget deadlines… We'll never have an institutional advocate on campus who can speak with a single voice to administrators, to students, to donors, to publishers, to communities about the value of the digital humanities" (Sample 2010). The isolation among many digital humanists also means that effort is duplicated, as, for example, faculty at multiple institutions are developing DH educational materials similar to those being created elsewhere.

Networks provide a potential solution to isolation by linking people with shared research interests and enabling them to exchange ideas and expertise. Nancy Maron suggests that a campus-based network model-- whether with equal partners or "a strong central hub, like a library or a DH center, with many spokes" -- may be a preferred organizational model for DH, as it can balance experimentation and sustainability and combine units' strengths (Maron 2015). Beyond the campus, as Sample argues, researchers can build their own communities that transcend institutions and are more agile and resilient than formal organizations: "Stop forming committees and begin creating coalitions. Seek affinities over affiliations, networks over institutes" (2010). Networks can cultivate collective expertise and facilitate acting on common interests without getting caught up in bureaucracy or being limited by long-term obligations.

Indeed, digital humanists are participating in a range of networks, from global to regional to university-based. Many digital humanists are connected around the world through Twitter's virtual network. At the country or regional level, organizations such as Red de Humanidades Digitales (RedHD), NYCDH, and the Texas Digital Humanities Consortium (authors Spiro and Taylor are part of the steering committee of the TDHC) provide online platforms for researchers to discover each other and share information, as well as organize training and events. Within universities or university systems, digital humanities networks such as the Oxford DH Network and the University of Wisconsin-Madison's Digital Humanities Research Network coordinate events and build community among local digital humanists.

As powerful as these networks are, most do not provide funding for collaboration across institutions on research projects, nor do they organize common work on curriculum. Enter Resilient Networks to Support Inclusive Digital Humanities, a collaboration among George Washington University (GW), Rice University, Davidson College, and Prairie View A&M University funded by the Andrew W. Mellon Foundation in the spring of 2016. This network aims to advance digital scholarship by sponsoring collaborative projects among faculty, librarians and students and by developing openly available educational modules that can be used to form a DH curriculum. It brings together private research universities in Washington DC (GW) and Texas (Rice), a public historically black university in Texas (Prairie View A&M), and a private liberal arts college in North Carolina (Davidson College). The co PIs are a member of the library staff and a faculty member from each institution who, together with the project director, oversee the program through bi-weekly online meetings and occasional face-to-face meetings. An Advisory Committee provides strategic guidance for the project.

Between the spring of 2016 and the spring of 2018, Resilient Networks will create:

- A set of openly licensed, adaptable educational modules on digital humanities that can be used in different contexts, such as workshops and semester-long courses. Planned modules include introduction to digital humanities, data in the humanities, the ethos of digital humanities, and framing projects for the public, as well as electives on topics such as text mining and database design and development.
- Cross-institutional projects in which a faculty member, librarian and students collaborate on digital humanities research. To facilitate the cross-institutional projects, Resilient Networks is awarding faculty $5000 jump start packages as seed funding; one is being granted at each institution during year 1, and three during year 2.
- A group of librarians, faculty, and students knowledgeable about digital humanities methods and collaborative approaches. In August 2016, a small group of faculty and librarians gathered at GW for a training workshop on DH project development and humanities approaches to data facilitated by Trevor Munoz. In addition, the Network sponsored a THATCamp at the Digital Frontiers conference hosted at Rice in September 2016 and a THATCamp at George Washington University in March 2017. The network will further support training by organizing THATCamps and providing funding for members to attend intensive DH workshops.
- Intra- and inter-institutional relationships that will facilitate ongoing DH collaborations. Many networks depend on strong personal relationships. Through collaborative work on research, curriculum and training, the Resilient Networks will develop such relationships, laying the foundation for ongoing collaborations.

There are challenges in establishing the Network that are to be expected with a cross-institutional collaboration, including setting common goals, maintaining strong communication, negotiating different academic calendars and bureaucratic systems, and accomplishing tasks in the face of competing responsibilities. In addition, the sheer diversity of digital humanities methods makes it difficult to build a coherent community. On the upside, however, by working within the existing institutional structures at each university rather than creating a separate organizational unit, the work will more likely be sustainable in the long term and better serve the needs of the researchers at each institution. As Snyder cautions, "Decentralised networks that lack both institutional support and dedicated time spent in creating resources will face serious barriers; if there is no position that has explicit responsibility for developing the network, the network may fall by the wayside in the pressure of more urgent responsibilities" (2012). To mitigate this risk, Resilient Networks hired a Digital Humanities Project Director to organize program activities and manage day-to-day operations. Establishing inter-institutional and cross-institutional ties will leverage already-established organizational structures rather than creating new ones. We expect the network to scale to include more institutions, which will expand available expertise. We will be conducting assessments to evaluate the various aspects of the resilient network model to determine its effectiveness in meeting our overall objectives.

In this short paper, we will discuss the network model for digital humanities research and education, results from the first year of "Resilient Networks," and future plans.

'The Royaltie of Sight': A 3D-GIS recreation of 'prospects' and 'perspectives' within an English designed landscape, c.1550–1660

Elizabeth Eleanor Rose Stewart
lizzie.stewart@uea.ac.uk
Univeristy of East Anglia, United Kingdom

Introduction

In 1624, Henry Wotton highlighted the importance of "the Properties of a well-chosen Prospect", a concept of viewing landscapes, which Wotton dubbed "the Royaltie of Sight" (Wotton, 1624, p.14). Sixteenth- and seventeenth-century English designed landscapes were artificially organised to optimise the 'prospect' whilst reflecting the landowners' individual perspectives. However, little analysis has been attempted into determining the extent and characteristics of 'prospect' and 'perspective' at specific sites. The destruction and modernisation of estate landscapes has hindered their analysis and reshaped perceptions of their appearance and development. In this paper, I will therefore demonstrate how 3D-GIS has the capabilities to change this. For my ongoing PhD research, I am introducing 3D-GIS as a new computational tool for producing 3D representations of estate landscapes but also to subsequently provide the geographical and historical context to analyse the visual experience within them. This methodology will contribute to not only the study of designed landscapes but of historic landscapes generally.

Literature Review

In the study of designed landscapes, country houses, gardens, parks, and the wider estate landscape have been individually and collectively explored and analysed. This is evident from the literature produced in disciplines such as literary history, art history, architectural history, garden history, archaeology, geography, and landscape history. Whilst each approach has its own merits, a noticeable lack of collaboration and acknowledgement of alternative methods has created a "disciplinary vacuum" (Spooner, 2010, p.7). In my research, landscape history is the leading discipline, but it also embraces the contributions of the other disciplines, thus creating an altogether multidisciplinary approach.

Our current understanding is predominantly based on research into well-documented and surviving estates. Consequently, there is a bias against sites which no longer survive or are lacking in evidence. Additionally, they are analysed separately from the wider landscape, which is frequently overlooked despite its significant bearing on the development and utilisation of designed landscapes. Although its contributions have been mentioned, the wider landscape has not been examined in detailed concordance with designed landscapes (Dix, 2011, p.152).

As a result, little research exists into how individual estates were experienced within their landscape context. Whilst the history of the senses, experiences and attitudes towards the landscape have been researched (Rippon, 2012; Hamilakis, 2013; Whyte, 2015), the examination and application of these concepts to historic landscapes, including designed landscapes, is minimal. Therefore, a greater understanding of contemporaries' perceptions and experiences of designed landscapes can be reached by ascertaining how such notions were applied to individual estates.

In this paper, these issues will be addressed and a solution provided. This project utilises computer science as a conduit to address the many disciplines already featuring in the study of designed landscapes. Geographical Information Systems (GIS) is becoming increasingly popular in the spatial humanities, particularly historical and landscape studies (Gregory and Geddes, 2014; Knowles (ed.), 2002), but few have used GIS to analyse individual designed landscapes (Dalton, 2012) and 'prospects' within them (Spooner, 2009). Furthermore, 2D-GIS is typically used, which does not provide a suitable perspective for comprehending the intended experience within these landscapes. On the other hand, Computer Aided Design (CAD) can digitally restore lost landscapes (Virtual Past, n.d.), including designed landscapes (Urmston and Historic England, n.d.), thus providing equal opportunity for their examination alongside surviving specimens. However, the essential difference between GIS and CAD is the handling of spatial data, and CAD is unable to conduct further spatial analysis (Abdul-Rahman and Pilouk, 2007, pp.4–5). Therefore, by incorporating CAD into a GIS environment, 3D-GIS can provide a more immersive perspective for the analyst to explore and analyse these landscapes more appropriately and effectively.

3D-GIS is, therefore, a promising approach for the study of historic landscapes. Regarding designed landscapes, the reconstructive capabilities of 3D-GIS have been demonstrated (de Boer et al., 2011). However, 3D-GIS has only more recently been trialled for the analysis of individual estates. This project builds upon my previous work, looking specifically at the 'prospect' with the use of 'viewshed' analysis (Stewart, 2015). By literally adding a new dimension, 3D-GIS has great potential to improve our understanding of designed landscapes.

Case Study

In this paper, I will present a case study which demonstrates the potential of 3D-GIS. My work adopts a regional approach, focusing on Norfolk, Suffolk and Essex. I will present work from one of these geographical areas. The combination of the aforementioned disciplines will provide the foundations upon which the recreations within CAD and GIS can be supported. This will involve the utilisation of polygons and imported CAD models, based on data extracted from geo-referenced contemporary maps, architectural plans, earthwork plans, fieldwork and archaeological surveys, alongside a range of qualitative historical documents, including estate accounts, inventories and contracts.

Once digitally recreated in 3D-GIS, the estate along with its landscape context can then be subjected to further spatial analysis. For the purposes of this study, the visibility of a 'prospect' can be ascertained using 'viewshed' analysis. To calculate this, topographical data produced by LIDAR is required, with amendments to replicate the historic landscape recreated in 3D-GIS. Viewshed analyses are then conducted from predetermined vantage points. Landowners ensured that 'prospects' could be enjoyed from certain places within their estates, such as the piano nobile of the country house, the rooftop, and from structures and landscape features within the grounds of the estate. Coupled with animations, whereby the act of movement throughout the landscape can be generated, the 'prospects' that contemporaries experienced can be recreated from these positions within the landscape.

Finally, the results can be interpreted in light of the evidence analysed using 'reception theory'; the creativity and reactivity of individuals in response to certain works (McGregor and White, 1990, p.1). This will focus on each individual landowner's possessions, such as published texts or artwork, but also personal correspondence, including letters and diaries. This research will utilise reception theory, which has not yet fully implemented into the study of designed landscapes (Hunt, 2013, p.7), in order to ascertain contemporary 'perspectives' towards these landscapes through the 'prospects' experienced within them. I will present the findings from this case study. This will demonstrate not only the synthesis of the approaches and resources addressed, but will provide the best opportunity to analyse the visual experience and thus improve our understanding of sixteenth- and seventeenth-century designed landscapes.

Conclusion

The potential of 3D-GIS to rekindle the analysis of sixteenth- and seventeenth-century designed landscapes will be evident. The results from this case study, as part of a larger study, will help to explore and examine what these landowners' visual perceptions were. Subsequently, our understanding will improve regarding how individual landscape designs have been influenced by their landowners' thoughts and ideas, and the extent of their individuality or conformity to contemporary fashions in landscape design and appreciation. My project will progress research into designed landscapes whilst demonstrating the methodological benefits of 3D-GIS. As a virtual environment, analytical tool, and database, this approach can subsequently contribute to studies in landscape conservation, heritage management and outreach activities, with scope to benefit research within other areas of the spatial and digital humanities.

Introduction

Les rapports entre les technologies du numérique et les Sciences Humaines et Sociales (SHS) sont aujourd'hui profondément renouvelés par le développement des Humanités numériques. Les mutations en cours permettent en particulier de repenser les pratiques d'enseignement et d'éducation au numérique. Voir en particulier le très récent ouvrage rédigé de manière collaborative lors du Edcamp qui s'est tenu à Paris les 1er et 2 septembre 2016 (Bourgatte et al., 2016). Parmi ce vaste chantier, la problématique de la recherche et de l'accès à l'information semble primordiale. Elle représente en effet une part importante du travail quotidien des chercheurs et des étudiants en SHS et se trouve profondément bouleversée par le tournant numérique. Celui-ci se matérialise par l'explosion du nombre de ressources disponibles en ligne et par une plus grande hétérogénéité des documents et des moyens d'accès. Si la disponibilité immédiate de documents jadis inaccessibles, faute de moyens ou de temps, est un atout précieux pour la recherche actuelle en SHS, il n'en reste pas moins que les activités de recherche et d'accès à l'information requièrent des compétences pointues et une expérience significative pour être véritablement maîtrisées. Le numérique pose à cet égard des problèmes spécifiques qui doivent être pris en compte dans la formation des étudiants.

Des travaux récents ont montré que la numérisation des documents et leur mise à disposition en ligne étaient loin de permettre un accès universel et transparent au matériau de la recherche (Milligan, 2013). Des problématiques techniques, méthodologiques et cognitives limitent notre compréhension de l'accès à l'information (Cardon, 2013). Sur le plan technique, la distinction généralement opérée entre « information seeking », l'ensemble des processus et pratiques des utilisateurs pour répondre à un besoin d'information et « information retrieval », les méthodes et techniques informatiques qui permettent au système de répondre à ces besoins est fortement significative (Buchanan et al., 2005). Il existe un fossé entre les besoins des utilisateurs et les technologies utilisées pour y répondre. Il est ainsi souvent difficile de comprendre les relations de causes à effets entre les critères de recherche (inputs) saisis par l'utilisateur, et les résultats (outputs) fournis par le système. Ce fossé sémantique se décompose en de multiples problématiques. Sans faire ici une liste exhaustive, les exemples ne manquent pas. Les technologies de reconnaissance optique de caractères (OCR), par exemple, génèrent des erreurs qu'il est complexe d'identifier et de mesurer. L'indexation des documents, quant à elle, repose sur des catégories développées par d'autres, dont les utilisateurs n'ont bien souvent pas connaissance. Les paramètres des algorithmes de pertinence, de personnalisation et de classement des résultats sont inaccessibles alors même qu'ils régissent la manière dont sont générés et classés les résultats des recherches en ligne.

Ces transformations subies par les données (des inputs aux outputs), inconnues des utilisateurs, sont des boîtes noires. Les étudiants doivent avoir conscience de leurs effets et doivent pouvoir les intégrer à leur appareillage critique. L'outil que nous développons poursuit deux objectifs:

Dresser des ponts entre les opérations menées par les systèmes d'accès à l'information et l'idée que s'en font les utilisateurs. Notre outil a ainsi pour vocation de mettre en lumière et permettre d'expliquer l'ensemble des transformations que subissent les données et les documents dans le cadre de l'interaction entre un utilisateur et un système de recherche d'information.

Mettre les étudiants en situation expérimentale de recherche d'information et permettre d'en visualiser les résultats individuels et collectifs. Ces résultats doivent ensuite pouvoir être réinvestis dans une discussion interrogeant la démarche et la méthode de recherche d'information dans un contexte numérique.

Environnement technologique et fonctionnalités

L'outil que nous développons est un moteur de recherche et une interface de bibliothèque numérique reposant sur le framework libre Hydra (Apache Solr, Fedora Commons et Blacklight), capable d'indexer des sources primaires comme secondaires. Il est conçu pour être utilisé lors de séances de cours dirigées par un enseignant où les étudiants doivent répondre à un besoin d'information défini par le formateur.

Figure 1 : Interface principale de l'outil de recherche

Sur la base du framework Hydra, nous ajoutons des composants qui documentent la requête effectuée par l'utilisateur et fournissent des informations supplémentaires dont :le résumé de la requête transmise au moteur de recherche (mots, expressions et filtres); les paramètres du moteur (métadonnées interrogées ou ignorées, variations linguistiques utilisées ou ignorées, etc.); les procédures de classement des résultats utilisées (critères de pertinence, pondérations utilisées, etc.).

Cette documentation supplémentaire permet d'afficher à l'utilisateur des compléments d'information pour chaque requête qu'il effectue dans le moteur de recherche. Il lui est alors possible de comprendre comment a été décomposée sa requête, quels paramètres extérieurs à son contrôle ont été appliqués et comment ont été calculés les résultats.

L'enseignant qui dirige une séance peut par ailleurs agir sur certains paramètres du moteur de recherche, pour modifier dynamiquement la manière dont celui-ci réagit aux inputs des utilisateurs. Il est par exemple possible de modifier le comportement de l'algorithme de pertinence, de changer la présentation des résultats ou encore d'activer et désactiver l'usage de certaines métadonnées. Ces options ont un impact important sur le comportement du moteur. Les étudiants peuvent immédiatement le mesurer et réfléchir à l'influence de ces paramètres cachés sur leur pratique de recherche.

Durant la séance, l'outil garde également une trace de l'activité globale de recherche de chaque utilisateur. Cette trace est élaborée grâce aux logs de l'application, que nous enrichissons de données liées au comportement de recherche des utilisateurs (Suire et al., 2016). Ces informations servent d'abord à générer des représentations personnelles et collectives des recherches effectuées durant la séance. Il est ainsi possible de débattre avec les étudiants des résultats obtenus, en se fondant sur les différentes approches et stratégies de recherche qu'ils ont développées. Par ailleurs, les données d'usage collectées par l'application sont utiles à l'évaluation de l'outil. Nous pouvons par exemple comparer le comportement des étudiants avant et après la formation, sur des tâches de recherche d'information de même nature et ainsi évaluer la pertinence pédagogique de nos développements. Nous complétons par ailleurs cette évaluation par des questionnaires et des entretiens qualitatifs, permettant de mesurer l'intérêt des étudiants pour la problématique, l'approche et les outils mis en place.

Figure 2 : Exemples de représentation visuelle: à gauche, un extrait du processus de recherche d'un utilisateur (ici identifié par le numéro 19) et à droite une représentation en réseau des documents consultés par cet utilisateur au regard de l'activité de l'ensemble du groupe.

Contexte expérimental et applications

Bien que l'outil soit encore en développement, nous menons des expériences afin d'évaluer son intérêt pédagogique et son fonctionnement. Nous expérimentons l'outil avec des groupes de 50 étudiants, en 2e année de cycle universitaire (Ces étudiants peuvent être considérés comme débutants, aussi bien en terme de connaissance du domaine qu'en terme de compétences en recherche d'information (Jenkins et al., 2003)), qui débutent leur spécialisation en Histoire. Lors d'une séance de 2 heures, ils bénéficient d'abord d'une courte présentation du fonctionnement de notre outil. Les étudiants ont ensuite 60 minutes pour élaborer une problématique de recherche à l'aide d'un corpus d'environs 300 documents hétérogènes (textes scientifiques ou institutionnels, documents iconographiques, etc.) relatifs à la thématique de la préservation du patrimoine. La séance se termine sur un échange de 40 minutes autour des indicateurs fournis par notre outil.

Lors de nos premières expériences, que nous présenterons plus en détail lors de notre communication, les thématiques de ces échanges ont été nombreuses. A titre d'exemple, les étudiants ont été surpris de leur tendance à se focaliser sur les premiers résultats calculés par le moteur de recherche, alors même que de nombreux documents pertinents se trouvaient dans les pages suivantes. Les capacités de représentations graphiques de notre outil ont également permis de mener une discussion constructive sur les différentes stratégies qu'il convient d'adopter face à ce type de besoin d'information. Les développements en cours permettront prochainement de simuler d'autres situations de recherche d'information courantes en SHS (Ellis, 1989; Savolainen, 2016). Ces premières expériences ont toutefois déjà témoigné de l'intérêt de mettre les étudiants en situation expérimentale, pour les engager dans une pensée critique de la recherche d'information dans un contexte numérique.

Introduction

Existing studies of anglophone digital humanities (DH) curricula have examined course syllabi (Terras 2006; Spiro 2011) and the development of programs at specific institutions (Rockwell 1999; Siemens 2001; Sinclair 2001; Unsworth 2001; Unsworth and Butler 2001; Drucker, Unsworth, and Laue 2002; Sinclair & Gouglas 2002; McCarty 2012; Smith 2014). This study adds to the literature on teaching and learning by presenting a survey of formal degree and certificate programs in anglophone DH.

While these programs represent only part of the entire DH curricula, they are important in several respects: First, they reflect intentional groupings of courses, concepts, skills, methods, and techniques, purporting to represent the field in its broadest strokes. Second, these programs include explicit learning outcomes, and their requirements form one picture of what all DHers are expected to know upon graduation. Third, formal programs organize teaching, research, and professional development in the field; they are channels through which material and symbolic capital flow and thereby shape the field itself. Finally, these programs, their requirements, and coursework are one way—perhaps the primary way—in which prospective students encounter the field and make choices about whether to enroll in a DH program and, if so, which one.

In addition to helping define the field, a study of DH programs also has the capacity to comment on pedagogical discussions in the literature. Hockey, for example, has long wondered whether programming should be taught in the field (1986) and asks, "How far can the need for analytical and critical thinking in the humanities be reconciled with the practical orientation of much work in humanities computing?" (2001). Also skeptical of mere technological skills, Mahony and Pierazzo (2002) argue for teaching methodologies or "ways of thinking" in DH, and Clement examines multiliteracies in DH (e.g., critical thinking, commitment, community, and play), which help to push the field beyond "training" to a more humanistic pursuit (2012, 372). Others have called on DH to engage more fully in critical reflection, especially in relation to technology and the role of the humanities in higher education (Brier 2012, Liu 2012, Walzer 2012).

These and other concerns point to longstanding questions about the proper balance of skills and reflection in DH. While a study of DH programs cannot address the value of critical reflection, it can report on its presence (or absence). These findings, together with our more general observations about DH activities, give pause to consider what is represented in, emphasized by, and omitted from the field at its most explicit levels of educational training.

Methodology

We compiled a list of 37 DH programs active in 2015, drawn from public listings (UCLA Center for Digital Humanities 2015; Clement 2015), background literature, and web searches (e.g., "digital humanities masters"). In addition to degrees and certificates, we included minors and concentrations in which humanities content was the central focus, and omitted digital arts and media programs in which this was not the case. Because our sources and searches are all English-language, it limits what we can say about global DH.

We recorded the URL and basic information (e.g., title, level, location) about each program and looked up descriptions of any required courses in the institution's course catalog. To analyze topics addressed in these programs, we applied the Taxonomy of Digital Research Activities in the Humanities (TaDiRAH 2014), which attempts to capture the "scholarly primitives" of the field (Perkins et al. 2014). TaDiRAH contains forty activities terms organized into eight parent terms ('Capture', 'Creation', 'Enrichment', 'Analysis', 'Interpretation', 'Storage', 'Dissemination', and 'Meta-Activities'). TaDiRAH was chosen for its basis in the literature on "scholarly primitives" (Unsworth 2000), as well as three earlier sources (an arts-humanities.net taxonomy, DIRT categories and tags, and a Zotero bibliography) and community feedback and revision.

We applied terms to program/course descriptions independently and then tested intercoder agreement, which was extremely low. We attribute this to the many terms in TaDiRAH, complexity of program/course description language, questions of scope (i.e., using a broader or narrower term), and general vagueness. We did find discussing our codings helpful and, in doing so, were able to agree. Accordingly, each of us read and coded every program/course description and discussed them until we reached consensus. Often, this involved pointing to specific language in the descriptions and referencing TaDiRAH definitions or notes from previous meetings when interpretations were discussed.

Findings and discussion

The number of DH programs has risen sharply over time, beginning in 1991 and growing steadily by several programs each year since 2008 (see Figure 1).

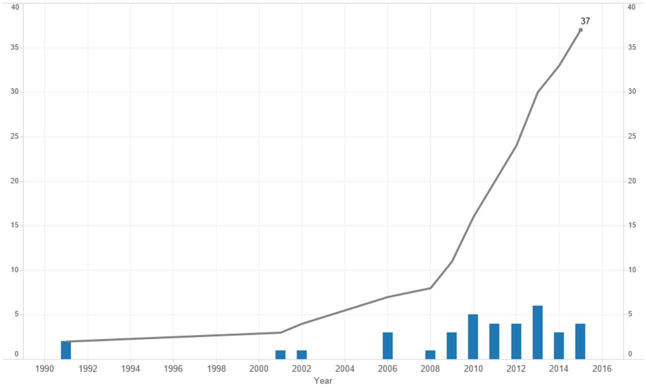

Figure 1. Growth of digital humanities programs in this study

Geography

Most of the programs studied here were located in the US (22 programs, 60%), followed by Canada (6 programs, 16%), the UK (5 programs, 14%), Ireland (3 programs, 8%), and Australia (1 program, 3%). We note that these programs are all located in Anglophone countries and that TaDiRAH, too, originates from this context, which necessarily limits what we can say about DH programs from a global perspective.

Structure

Less than half of these DH programs grant degrees: some at the level of bachelor's (8%), most at the level of master's (22%), and some at the doctoral level (8%) (Figure 2). The majority of these programs are certificates, minors, or specializations—certificates being more common at the graduate level and nearly one-third of all programs studied here.

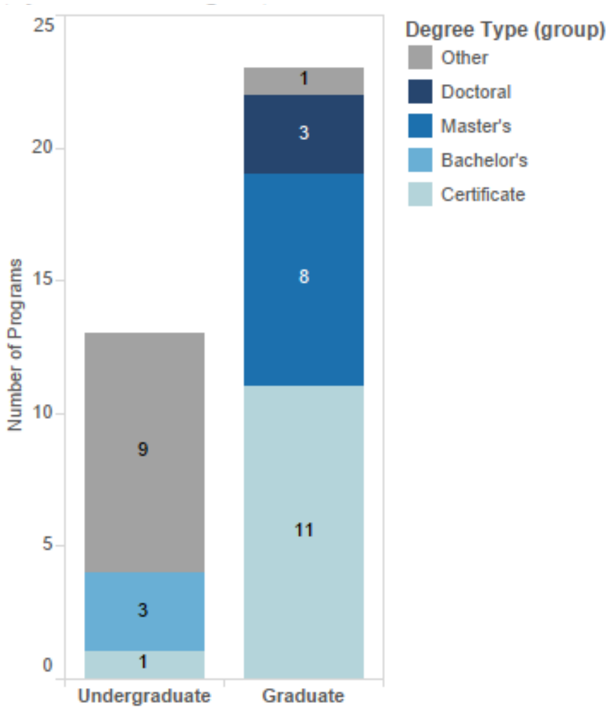

Figure 2. Digital humanities programs in this study (by degree and level)

We also examined special requirements of these programs, finding that half require some form of independent research (see Figure 3), and half require a final deliverable, referred to variously as a capstone, dissertation, portfolio, or thesis (see Figure 4). About one-quarter of these programs require fieldwork, often an internship (see Figure 5).

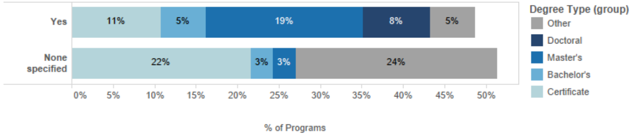

Figure 3. Independent research requirements of digital humanities programs in this study

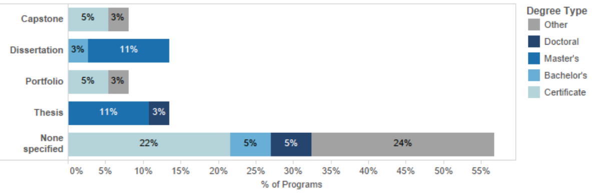

Figure 4. Final deliverable required by digital humanities programs in this study

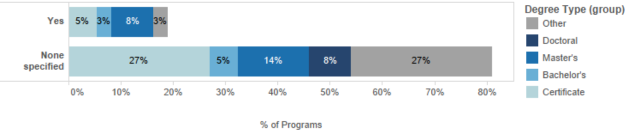

Figure 5. Fieldwork requirements of digital humanities programs in this study

Location & disciplinarity

Most of these programs are housed in colleges/schools of arts and humanities, but about one-third are outside of traditional schools/departments, in centers, initiatives, and, in one case, jointly with the library (see Figure 6). Most DH concentrations and specializations are located within English departments, commensurate with Kirschenbaum's claim that DH's "professional apparatus…is probably more rooted in English than any other departmental home" (2010, 55).

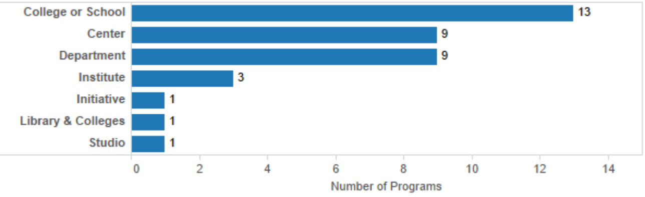

Figure 6. Institutional location of digital humanities programs in this study

Elective courses for these programs span myriad departments and disciplines, from humanities departments (art history, classics, history, philosophy, religion, and various languages) to along with computer science, education, information and library science, design, media, and technology.

DH activities

We analyzed our TaDiRAH codings in two ways: overall term frequency (see Figure 7) and weighted frequency across programs (see Figure 8). To compute weighted frequencies, each of the eight parent terms were given a weight of 1, which was divided equally among the subterms in each area. These subterm weights were summed to show how much of an area is represented, regardless of its size.

Analysis and meta-activities (e.g., 'Community building', 'Project management', 'Teaching/Learning') make up the largest share of activities, along with creation (e.g., 'Designing', 'Programming', 'Writing'). It is worth noting that 'Writing' is one of the most frequent terms (11 programs), but this activity certainly occurs elsewhere and is probably undercounted because it was not explicitly mentioned in program descriptions. The same may be true for other activities.

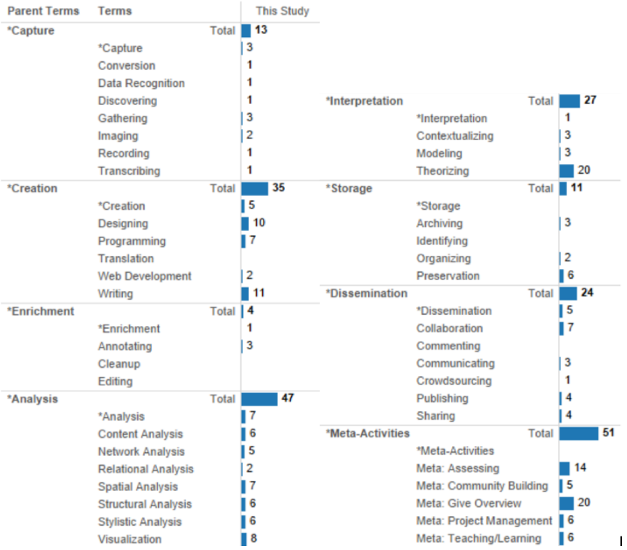

Figure 7. TaDiRAH term coding frequency (grouped)

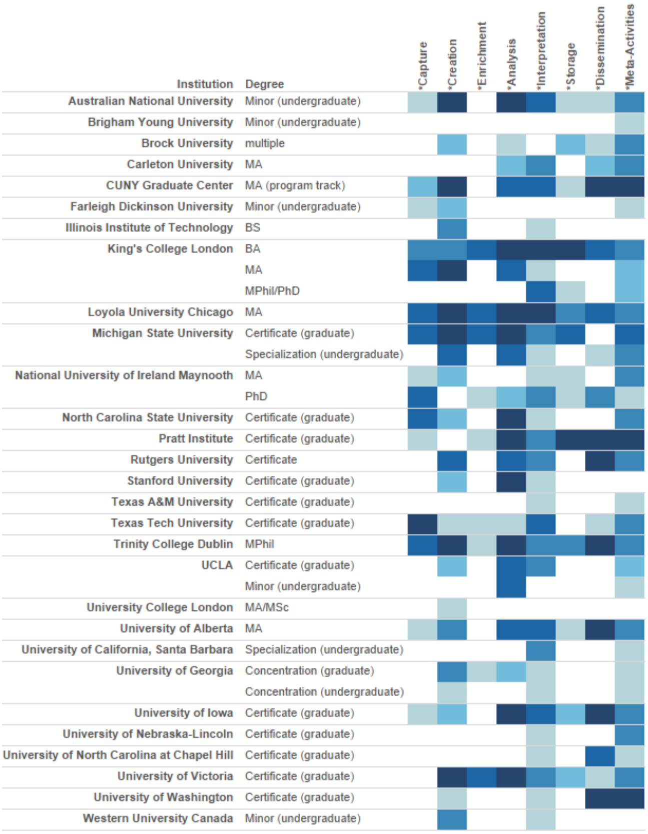

Figure 8. Digital humanities programs in this study and their required courses (by area)

Enrichment and storage terms (e.g., 'Archiving', 'Organizing', 'Preservation') were generally sparse (only 1.9% of all codings), but we suspect these activities do occur in DH programs and courses—in fact, they are assumed in broader activities such as thematic research collections, content management systems, and even dissemination. Generally, there seems to be less emphasis on content ('Capture', 'Enrichment', and 'Storage' terms) and more focus on platforms and tools ('Analysis' and 'Meta-Activities' terms) in the programs studied here—or at least, those may be more marketable to prospective students and institutions, two important audiences of program webpages.

Theory and critical reflection

To analyze theory and critical reflection, we focused our analysis on two terms: 'Theorizing' and 'Meta: GiveOverview', which we used to code theoretical or historical introductions to DH itself. We found that all programs studied here included some mention of theory or historical/systematic overview (see Figure 9). Our codings, of course, do not reveal anything further about the character of this reflection, whether it is the type of critical reflection called for in the literature, or how it interfaces with skills and techniques in these programs.

Further directions

We plan to publish our data and visualizations publicly for researchers, students, and those developing curriculum: http://bit.ly/DHprograms. We believe it provides a baseline of field growth, areas, structure, and learning experiences, which can be used to measure changes in future, in addition to providing a data-driven perspective on the field today.

In that respect, we hope this study gives the community pause to consider how DH is described, represented, and taught. If there are common expectations not reflected here, perhaps we could be more explicit about those, at least in building our taxonomies and describing our formal programs and required courses. Conversely, if there are activities that seem overrepresented here, we might consider why those activities are prized in the field (and which are not) and whether this is the picture of DH we wish to present publicly.

Sharing Surgical Scars: Social Networks and the Many Gendered Meanings of Mastectomy

K. J. Surkan
ksurkan@gmail.com
Massachusetts Institute of Technology
United States of America

In most Western cultural contexts, the surgical modification of the female breast is usually presumed to take place in the context of cosmetic surgery primarily aimed at breast enhancement for the cisgendered female. The cultural obsession with sexualizing breasts as a signifier of both heterosexuality and femininity has meant gender trouble for breast cancer patients (and BRCA "previvors") seeking flat mastectomies, as well as transmasculine, genderqueer, and FTM individuals electing top surgeries. Whereas trans studies critiques have traced the emergence of (and subsequent resistance to) a prescriptive medical narrative authorizing gender affirming top surgeries, only recently have some in the breast cancer community begun to form identity groups around non-reconstructive surgical choices and an embrace of "flatness" on social media. This presentation is a comparative study of the reported experiences and rhetorical choices of social networks of two flat mastectomy groups: those pursuing mastectomy for reasons of gender affirmation, and those for whom mastectomy is primarily a treatment for cancer or cancer risk. The emergence of the Flattopper Pride movement within the breast cancer community represents a queering of conventional (female) breast reconstruction, offering feminist rhetoric that resists presumptions about the "natural" embodiment of femininity while occupying a position that is at once informed by transgender surgical narratives (and counter-narratives) yet articulates a distinctly different relationship to surgical modification of the female body. The circulation of mastectomy images through trans, queer fashion (Cat Walk & Play Out underwear models), and e-patient breast cancer communities represents three distinct yet overlapping discursive contexts in which mastectomy derives cultural meaning. Through an exploration of how mastectomy images are circulated, censored, and shared in a variety of social media networks and support groups, feminist and queer critiques of surgical mastectomy options can be seen to emerge and create cross-influence between breast cancer, transgender, and genderqueer communities.

Access(ed) Poetry. The *Graph Poem Project* and the Place of Poetry in Digital Humanities

Chris Tanasescu (MARGENTO)

University of Ottawa, Canada

The *Graph Poem Project* at University of Ottawa develops tools for poetry computational analysis and applies graph theory and network graph computational apps in structuring, analyzing, and visualizing poetic corpora. The concept involves generating network graphs (multigraphs) in which the vertices are poems and the edges represent various commonalities between poems in terms of subject, diction, form, style, and other criteria. By computationally analyzing the network graph certain extremely interesting and potentially useful information can be extracted regarding a specific corpus. For instance, by identifying cut vertices, we find out which poem(s) play a crucial role in the connectivity of the network and therefore also in the cohesion of the corpus, since by removing that particular poem-node the whole network becomes disconnected, and thus the corpus per se without that particular poem would become disarticulate and divided; and similarly, cut edges signal connections between certain poems that are of paramount importance in the connectivity of the entire network. Identifying cliques of nodes, on the other hand, for instance, shows how poems within a corpus are clustered and which parts of a specific oeuvre, collection, or anthology are more self-contained than others or which poems belong together across or within divides such as authorship, school, period or region, etc. More generally, representing corpora as network multigraphs makes possible analyzing and visualizing both small and significantly large datasets (so far up to hundreds of thousands) of poems, and reach certain information and conclusions about both particular poems in that corpus and the corpus as a whole or as compared to other corpora.

This is one of the first respects in which the issue of access becomes of dramatic importance for our research and for developing and testing our tools; and virtually for any contemporary digital project in poetry. Namely the access to databases and the ability to convert existing files into formats that are compatible to computational processing and analysis. The paper will focus on the existing databases, will review previous work in the field and analyze the kind of data they have employed, will examine the premises and prospects for big data and/or data intensive research in poetry (one of the main tenets of our project), and the arguable absence of such approaches in the published research in the area so far. Terms like “crawl” and “rip” for the poetry available online, and issues related to digitization and/or computationally analyzing poetry in print will also be placed under close scrutiny while we will also report on our own solutions and results, and compare them to those in other projects in digital humanities (DH), digital literary studies, or computational linguistics/analysis.

Our research, tools, publications, and future work will therefore be then presented in a comparative manner in the wider context of current trends, theories, and debates in DH in general and text analysis in particular—by considering for instance the potential relevance of the *Graph Poem Project* to at least some of the issues raised in the “Forum: Text Analysis at Scale” section of *Debates in the Digital Humanities 2016* (eds. Lauren F. Klein and Matthew K. Gold), or literature-related tools/projects such as Syuzhet or heureCLÉA—, in natural language processing (NLP)—by reviewing other projects that have dealt with literary computational analysis and particular poetry processing, but also other works that focused on various issues in computational linguistics, such as syntax or trope processing and analysis—, and in digital pedagogy, by relating it to other poetry related digital pedagogical projects (such as those reviewed by Chuck Rybak, for instance, in *Digital Pedagogy in the Humanities*). “Access” therefore will turn out to encompass quite a few different meanings and phenomena. In terms of text and data analysis, we will review existing debates and commentaries and contribute our own on the politics of developing poetry archives or assembling collections/anthologies, and the related issues of representationality, especially with regards to gender, race, minority, and so forth. In other words, the question asked will be, what is the access of certain authors and their works to our research and tools, what are their chances to be represented in the graph poem? Then, in terms of existing tools, accessibility refers to either the monetary aspects of acquiring or upgrading certain apps or to accessing the source code and/or repurposing it, and the discussion will gravitate around the political and cultural implications of such options. Access then also means accessibility of our tools to the user, in the sense of how easy or how complicated it is for ‘anybody’ to read our approach, use our apps, and employ our results; and why would they ever do it?—how are we trying to ‘seduce’ our audience? The paper will hence examine what are the “compromises” we have made in that respect—as for instance in picking 2 or 3 dimensions as rhyme sub-types in employing a certain API for displaying rhyme scores as scatter graphs—, and what are the actual efforts we are making in conveying the potential significance of sometimes arcane mathematical theories and algorithms for poetry. But on yet another level, access means success, namely the measure of our project’s access to levels of meaning (in Adrian Liu’s terms and not only) that may be deemed as ‘deeply’ or ‘typically’ poetic, an analysis that will combine notions of genre or craft related subtlety with pragmatic computational concerns, such as operationally consolidating numeric and non-numeric features and commonalities.

A more prosaic question to address will then be what is the access poetry really has to DH-related research, interest, and funding. Again, the data related to our own project will be compared to others, and the analysis will focus on the place of poetry in significant DH publications, periodicals, and platforms.

A cross-language comparison of co-word networks in Digital Library and Museum of Buddhist Studies

Muh-Chyun Tang
muhchyun.tang@gmail.com
National Taiwan University, Taiwan

Kuang-hua Chen
khchen@ntu.edu.tw
National Taiwan University, Taiwan

Introduction

This paper reports a co-words domain analysis of Buddhism literature collected by DLMBS (Digital Library and Museum of Buddhist studies) at National Taiwan University. Established in 1995, the DLMBS is one of the most comprehensive online repository of Buddhist research materials. It currently contains over 400 thousand records of books, research papers, theses and dissertations in 45 languages and digitized Buddhist scriptures. A controlled vocabulary, which is in five languages, including

Chinese, English, Japanese, German, and French, was used to help users search DLMBS's bibliographic database. By using co-occurrence data of author assigned keywords in the bibliographic records, this study attempts to generate co-word networks in three different languages, Chinese, English, and Japanese, to compare regional focuses on Buddhist studies.

Co-words analysis has been shown to be effective in mapping the intellectual structure of disciplines (He, 1999; Leydesdroff, 1989). While it has been widely used in the domains of sciences and technologies (e.g. Buitelaar, Bordea, & Coughlan, 2014; Ding, Chowdhury, & Foo, 2001; Bhattacharya & Basu,1998; Looze, & Lemarie, 1997; Peters & van Raan, 1993a, 1993b; Courtial, 1994; Tijssen, 1992; Callon, Courtial, & Laville, 1991; Rip & Courtial, 1984), to the best our knowledge, it has so far not been applied to humanities. Part of the advantage of using co-word in sciences and technologies is the highly codified subject languages, therefore a higher degree of consistency between concepts and terms in these fields. We believe that a cross-language co-word analysis of Buddhist studies literature would be a worthwhile endeavor for a couple of reasons: Firstly, it has been pointed out that there has been a wide variety of methods, perspectives and subject matters within the international communities of Buddhist studies. The heterogeneity of its scholarships can be partly traced to their geographic roots (Cabezón, 1995). It is therefore interesting to empirically study whether and how the intellectual structures reflected in the published literatures in these language communities differ from one another. A comparison of the intellectual structures can shed light on knowledge interests shared and distinct in these three language communities. From the methodological plain, co-word analysis also provides a viable alternative to citation-based network analysis in humanities where the citation structure is known to be much sparser than in sciences and technologies.

Procedures and analysis

Three separate co-word networks were generated in three different languages where nodes denote the keywords and edges the strength of their co-occurrence. Unlike in most of the previous co-words analysis, where keywords were extracted from titles and abstracts, author assigned keywords were used here as it is believed that they are more representative to the content of the articles and tend to have higher degree of consistency than keywords in free-text. For monographs and other types of publications, the subject-headings assigned by human indexers were used as keywords. Edge weights were normalized by both the inclusion and the Jaccard index (Courtial,1986; Callon, Law, & Rip,1986).

Thus three word similarity matrixes were generated so social network analytical methods such as cohesion, centrality and community-detection (Blondel et.al., 2008) could be performed with a view to exploring the social and cognitive structure of Buddhist studies manifested in its published literature in respective languages. Specifically, the study seeks to answer the following interrelated research questions: firstly, are there recognizable branches or specialties in Buddhist studies? If so, what might these areas of research be? Cross-languages comparisons were also made to examine the similarities and differences of the intellectual structure in different language communities.

Results

Descriptive data

Table 1 gives the numbers of items pertinent to various publication types analyzed in three languages in DLMB.

Language Publication Type	Chinese	English	Japanese

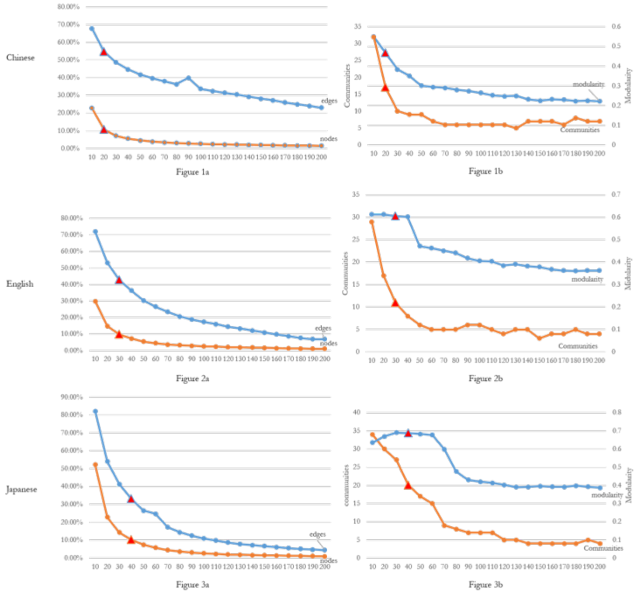
Book Review; Internet Resource	0	1	0
Total	68,688	38,560	43,625

Table 1. Types of publications analyzed

Due to the enormous size of the networks, some sorts of filtering are required to make the groupings intelligible; node degrees was used as the filter as many of the little connected nodes tend to generate noises that impairs meaningful interpretation. To determine the proper threshold of node degree, one needs to consider three criteria: the quality of the clustering, the interpretability of the individual clusters, and the preservation of information. A high threshold would filter out large amount of nodes hence the greater loss of information and low modularity values. On the other hand, a low threshold would result in difficulty in interpreting individual clusters as they tend to lump together heterogeneous topics. Thus a trade-off needs to be made. We approached this matter by performing modularity analysis at different threshold levels so the values of their modularity, the resulting number of communities, as well as the size of the networks could be recorded. The following heuristics were used to select the proper thresholds: to preserve about 10 percent of the total nodes, to limit the number of communities from 10 to 20, and to preserve a high degree of modularity, which is commonly used as the indicator of clustering quality.



Figure(1-3). Node degree thresholds and resulting network attributes in three languages

Table 2 reports the thresholds and their corresponding attributes of the resulting networks.

	# of nodes	# of edge	Threshold	# of Communities	% of nodes	% of edges
Chinese	58,808	787,682	20	17	10.66	54.61
English	34,093	325,161	30	11	9.66	42.74
Japanese	75,728	859,469	40	20	10.09	33.04

Table 2. Descriptive statistics of the three networks

After filtering out lesser connected nodes, modularity maximizing community detection method was then performed to identify the subdomains in each language network. A two-stage approach was adopted here. As some of the communities resulting from the first-round of clustering can still be very broad and heterogeneous, a second modularity analysis was performed on these relative "super" clusters (i.e. clusters with more than 400 nodes), the joint results produce a two-levels hierarchical structure. Three experts in Buddhist studies were then interviewed to help us interpret the clusters (See Figure 4 and 5).

Figure 5. Visualization of intellectual structure in Japanese Buddhist studies.

In this study we utilized co-words networks to visually represent the domain of Buddhist studies. A heuristic was proposed to help select the proper threshold in order to filter less significant keywords. A two-stage clustering approach was adopted, which arguably provides a finer representation of the intellectual structure of the domain. Further analysis will be done, with the help of domain experts, to compare the differences in the intellectual structure reflects in three language communities.

Reading Ancient Scripts: Investigating the Human Visual System for Artificial Intelligence in Palaeography

With the renewed vitality of research in Artificial Intelligence, thanks in particular to the continued development of neural network techniques for machine learning, computer vision technologies developed for handwriting recognition offer innovative ways of conducting research in palaeography (Brusuelas, 2016; Hassner et al 2014; Muzurelle, 2011; Stutzmann, 2015)

In this context where artificial intelligence often endeavours to replace human intelligence, or at least to emulate it, we are undertaking to understand better what it is that human intelligence does when reading ancient handwritten scripts. Ultimately, our ambition is to nudge artificial intelligence for palaeography to be intelligent enough to identify where human intelligence is still superior to machine intelligence (and therefore better left the upper hand) and where researchers can benefit from algorithmic support.

Handwriting recognition is a challenging task – both for humans and machines – because handwritten scripts inherently straddle two interlinked spheres of intelligence: that of visual shapes, and that of semantics.

This work builds on previous research (Terras, 2006; Youtie, 1963) that has identified six strands of human strategies in palaeography through ethnographic analysis, the results of which were cross-referenced with the cognitive sciences literature (Tarte, 2014). These strands were: visual perception, aural feedback, motor feedback, semantic memory, structural knowledge acquisition, and creativity; all continuously interacting with and feeding back into each other to some degree. In this project, we concentrate on the task of reading ancient handwriting – one of the many aspects of palaeographical research, whether it is concerned with mediaeval scripts or with more ancient scripts.

In this paper, we present some findings and observations made in the process of designing experiments to investigate some of the mechanisms underlying handwriting recognition in a palaeographical context; preliminary results from the experiments themselves are forthcoming.

To explore in depth how humans handle the variability of the shapes of signs in a given script, our experiments aim to bridge between traditional ethnographic methodologies, geared towards the gathering of qualitative data, and cognitive sciences methodologies, geared towards the gathering of quantitative data. The script of choice was Demotic, a script of the Late Egyptian language and whose use spanned ten centuries, therefore displaying a large variability in shapes. The team of scholars involved in designing and conducting our experiments was made of: an Egyptologist/Classicist, an Ethnographer, a Neuroscientist, and a Computer Scientist. Many of the observations reported here stem from the epistemological encounters of very different traditions of research; they emerged through the interdisciplinary conversations that took place in the process of designing the experiments.

The outcome of these conversations was the following experimental setup, building on the principles of the protocols outlined by Althaus and Plunkett (2015) and Longcamp et al (2008).

Experiment

Volunteers are invited to two experimental sessions that take place in a library setting, where they interact with a tablet computer using a stylus. The first session is a learning session and the second is a delayed recognition session. The sessions take place at least one week apart.

During the learning session volunteers learn to recognise 5 Demotic signs (target signs). This session comprises of a familiarisation phase followed by an immediate recognition phase. The familiarisation phase can comprise of one of the following three familiarisation conditions:

- static passive familiarisation – 3-second repeated presentation of each sign
- static active familiarisation – repeated presentation of each sign with time for the volunteer to draw the sign on the tablet using the stylus
- dynamic familiarisation – 3-second repeated presentation of movies depicting the drawing of each sign

During the familiarisation phase each sign is presented 8 times, twice in each of 4 distinct hands. The presentation order is pseudo-randomize to ensure that signs don't appear twice in a row. Each volunteer is assigned randomly to one of the three familiarisation conditions. The familiarisation phase is followed by a 2-step immediate recognition phase. In the first recognition phase, pairs of Demotic signs are presented; each pair is made of one target sign and one distractor sign (the distractors are also Demotic signs), and in the second recognition phase words containing the target sign are presented.

The delayed recognition session comprises of three phases: a delayed recognition, a repeated familiarisation and a re-enforced delayed recognition. The two delayed recognition phases are similar to the immediate recognition phase, while the repeated familiarisation is similar to the familiarisation of the learning session.

At the first session, all volunteers are given a short video introduction that aims to prime them towards scripts and writing before starting the experiment; the second session ends with a debrief where volunteers are given the freedom to ask questions about the tasks or scripts to the experimenter.

Negotiations

In the process of designing this experimental setup, a number of fascinating questions emerged due to the intrinsic multidisciplinary nature of the project. The main interdisciplinary negotiations that took place can be summarised thematically as revolving around: the definition of an alphabet; the nature of script and materiality; and biases and mixed methodologies.

Alphabet

As the researchers and the volunteers evolve in an environment where the default script is alphabetic, we decided to choose an alphabetic script. The choice of Demotic can therefore be questioned: Demotic is not an alphabetic script, even if most of its signs have a phonetic value. We wanted however to use real data – as opposed to an invented alphabet – so was there any context in which Demotic might have been used as an alphabet? From the Ptolemaic period onwards, the frequency of Greek names in Egypt is higher, and therefore documents bearing Greek names resort to transliterating them into Demotic. Although there was no received orthography for those transliterations, it becomes more acceptable, in this specific context, to consider Demotic signs as alphabetic signs (for the purpose of this experiment, determinatives, when present, were regarded as not part of the word).

In turn, this deliberate choice also made a search for images of signs written in different hands easier. By querying http://www.trismegistos.org/ (Brouz and Depauw, 2015) for a list of Greek personal names in Demotic documents, and cross-referencing the results of this search with those from a query on papyri.info for all papyri in Demotic that have accompanying digital images, it was possible to identify and isolate images of Greek personal names written in Demotic on papyri.

Nature of script and materiality

The question of the homogeneity of the signals presented to the volunteers is important in the cognitive sciences. However, isolating the signs from their support means possibly removing information (e.g. faint ink on more salient fibres of a papyrus, degraded or stained papyri). So in an effort to present realistic data, we have decided to use greyscale images, to crop the images of words/signs and to simply uniformize the overall look of the images of words by aligning their histograms; we have also endeavoured to present all signs in such a way that they have a similar size (so some scaling was performed).

A further question was that of the phonetic dimension of the script. From a cognitive sciences perspective, as the focus is on the visual, it didn't make sense to add a phonetic element to the script at this stage. Only when it is better understood how the visual processes handle variability in shape, can it be envisaged to add a multisensory layer of complexity.

This raises some intriguing questions with regard to the nature of a script. In particular, isn't the essence of an alphabetic script to be a notation system for phonetic word utterances? What does the removal of its phonetic dimension entail for the script (regardless of whether the existing phonetic dimension is a modern convention or an actuality)? Are we denaturing the script by presenting its signs stripped of their phonetic values?

Biases and mixed methods

Negotiating between the highly-controlled design of experiments in the cognitive sciences and the naturalistic settings and exchanges of ethnography proved complex. The main concern in such endeavours is to not compromise the validity of the gathered data with respect to the frameworks of the traditional disciplines. Free exchanges between volunteer and experimenter have the potential to bias the overall results for the cognitive sciences, as the bias is uncontrolled; it was therefore important for any such exchanges to happen only after all data of the controlled variables are collected.

Even then, leaving space for free exchange within the confines of the experiment worried the cognitive scientists who feared to open the door to highly irrelevant questions or even somewhat leftfield questions (e.g. "Can you see my gift of clairvoyance?") It appeared that such questions might be favoured by the running of such experiments in medicalised environments (hospital, psychology department), so we ran our experiments at the library instead, thereby establishing an environment resonant with our overarching theme of reading.

The process of designing these experiments as well as the forthcoming results have some bearing on the understanding of expertise of course, but also on how one might proceed when faced with a large corpus of unedited textual artefacts: Can crowdsourcing approaches be specifically geared towards the strength of the human visual system? Can algorithmic approaches palliate the weaknesses of the human visual system?

Generous and Generative Communities for the Digital Humanities with the Digital Library of the Caribbean and Caribbean Studies

Laurie N. Taylor
laurien@ufl.edu
University of Florida, United States of America

Introduction

The digital humanities offers the promise and potential for global, multilingual, and multicultural collaborations as enabled by digital technologies that deliver public-facing scholarship that enriches and expands research communities. Realizing that potential requires approaches that embrace complexity, spanning the technological, social, procedural, and community concerns. In 2016-2017, the Digital Library of the Caribbean (dLOC) is undertaking a research project to study and advance support for the Digital Humanities specifically with Caribbean Studies, focusing on leveraging technologies to support public-facing scholarship, open access to research and results, enabling digital humanities research publications with technologies that meet access needs, and collaboration among scholars and communities. This presentation provides background on dLOC as a digital library, dLOC's evolution into a community connecting place and platform for digital humanities and Caribbean Studies, and the opportunities and needs for the digital humanities for enlarging scholarly and worldwide community access to Caribbean Studies.

About dLOC

The Digital Library of the Caribbean (dLOC) is a unique, open access, collaborative, international, multi-lingual digital library for resources from and about the Caribbean and circum-Caribbean, providing access and ensuring preservation for Caribbean materials (digitized and born-digital) and public-facing scholarship.

dLOC focuses on how a community of practice can best create a digital library in terms of contents, functionality, and robust governance for inclusivity and diversity. In dLOC's governance and operational model, partner institutions agree to shared goals and processes following a governance structure for: inclusive and distributed collection development where partners select materials, permissions-based infrastructure (partners retain all rights to materials), functional hubs, decentralized/local digitalization and digital curation, collaborative activities to develop the community of practice and increase capacity through collaboration. For all of this work—spanning tools for digitalization, online digital library functionality for patrons and users, tools for advanced querying and mining, and tools for automating reporting and user management which are necessary for operations at scale and reports to different governmental and academic entities—dLOC's technologies have been defined by and created in collaboration with partner institutions and scholars. Thus, over the past 12 years, dLOC has developed through collaboration into as a socio-technical (people, policies, communities, technologies) platform supporting collaboration among partner institutions, developing and enhancing communities of practice, and building intellectual infrastructure.

dLOC, Caribbean Studies, and Digital Humanities

dLOC originally focused on building content, and has grown into one of the largest open access collections of Caribbean materials with over 2.5 million pages of content, over 40 partner institutions (universities, colleges, libraries, archives, museums, government agencies, NGOs, publishers, and scholarly societies, as well as many contributing scholars and private collectors), and over 3 million views each month. With this growth, the dLOC Executive Committee, Scholarly Advisory Board, and full community recognized the need to emphasize new stages of development, specifically focused on further engaging scholars in digital humanities practices that build upon dLOC's commitment to access, preservation, the production of public-facing scholarship, and engaging across institutions and communities to further the community of practice as a constellation of communities of practice where all involved are leveraging the affordances of technology to further public humanities and interdisciplinary aspects of modern scholarship.

In 2016, the dLOC Executive Committee charged the dLOC Digital Scholarship Director with undertaking research into next steps for dLOC's socio-technical development (people, policies, technologies, communities) in relation to new opportunities with the digital humanities. dLOC currently supports the digital humanities in many forms, including curated materials and collections, digital humanities exhibits, pedagogical resources, teaching guides, and supporting faculty in developing online research and teaching materials.

dLOC's work in the digital humanities grapples directly with questions of access in the digital age. For example, one of dLOC's digital humanities projects is *Haiti: An Island Luminous*. *Haiti: An Island Luminous* began when then-PhD student Adam Silvia recognized the importance of materials about and from Haiti in dLOC, both for the significance of each item and for the sheer scale of materials available. Many of the materials in dLOC were not known to exist in the world, before being located by partner institutions and then digitized. Once the materials became available, the necessary scholarly and information ecosystems to link and cite the items was not in place. Indeed, scholars would be unlikely to search for items that were believed to have been lost to history. To create the necessary community connections, Silvia contacted members of the dLOC team and began collaborating to develop what was planned as an online exhibit to showcase materials. As the project began, the scope continued to grow. In its final release, *Haiti: An Island Luminous* is a curated edited online collection with contributions from over 100 of the top Haitian Studies scholars. *Haiti: An Island Luminous* is in English, French, and Kreyòl, and has been taught in schools in Florida and Haiti. Developed first online, the site is being developed for offline use on standalone kiosk/tablet installations, to meet access needs despite limited connectivity. Discussions are underway on the possibility of a print version to meet needs for limited online and electrical access, with the print version to include all pages from the curated edited collection online, samples of items, and with an accompanying USB drive.

Another example of dLOC's digital humanities work is the course "Panama Silver, Asian Gold: Migration, Money, and the Making of the Modern Caribbean." The course focused on the lesser studied Asian and Indian indenture in the Caribbean and was a Distributed Online Collaborative Course (DOCC), taught in multiple semesters and multiple iterations, most recently with the teaching team comprised of faculty, librarians, and archivists at the University of the West Indies, Cave Hill Barbados, University of Miami, University of Florida, and Amherst College. This collaboratively developed and taught course engaged the teaching team and students across all of the campuses in the use of materials in dLOC, other digital resources, and not-yet-digital resources held at each of the institutions to create new works of digital scholarship with students from different campuses working collaboratively. The course is underway for revision to focus on migration and mobility, to further expand the potential collaborators and fields engaged in this interdisciplinary collaborative course.

Both the DOCC series and *Haiti: An Island Luminous* present real examples of imagined possibilities for expanding Caribbean Studies in the digital age for creating public-facing scholarship, enhancing access to scholarly works, opportunities from the digital humanities in pedagogy and academic curricula, and the potentials for access as enabled by collaboration among scholars and communities.

Expanding Access through dLOC for Caribbean Studies and Digital Humanities

Caribbean Studies is an interdisciplinary field with broad connections across languages and cultures. dLOC takes its definition of the Caribbean from the Association of Caribbean University, Research, and Institutional Libraries, which defines the Caribbean as “the area of the Caribbean archipelago, the mainland countries including the Guianas, and the states of the United States which border on the Caribbean Sea or Gulf of Mexico.” Even this is immediately expanded with diasporic connections. dLOC’s success as a digital library is made possible by the recognition that the Caribbean exceeds the boundaries for any specific geographic area, language, or field of study, and by the generous framing for Caribbean Studies with the respect and support for interdisciplinary and diasporic connections.

dLOC was founded to meet the needs for preservation and access as a first step in supporting expanding the field of Caribbean Studies. As both the series of DOCCs and *Haiti: An Island Luminous* demonstrate, simply creating online access to materials is only part of the equation. As Adam J. Banks explains in *Race, Rhetoric, and Technology: Searching for Higher Ground*, access includes material access, which is met with materials being online, at least for those with online access and the functional access to be able to find and use materials. The digital humanities offers ways of conceiving and creating the means for experiential access, where materials are relevant for people’s lives, and transformative access, where there is “a genuine inclusion in technologies and the networks of power that help determine what they become, but never merely for the sake of inclusion” (45).

This presentation will review methodologies and results from the 2016-2017 research on the digital humanities and Caribbean Studies. The research includes site visits to the US Virgin Islands, Jamaica, Barbados, Curaçao, Trinidad, and Leiden (for the Dutch Caribbean Archives) to discuss current activities, projects, terminology, and framing to enable connections across communities. The site visits include engagement with scholars from multiple fields, museum professionals, librarians, archivists, governmental representatives, educators, and others. All materials from the research visits are shared with communities engaged and connected with Caribbean Studies through conferences and various means. This grounded approach allows for identification, recognition, and connection of digital humanities work being done, even when not previously labeled as such. The presentation will include findings on how dLOC is enabling responses and activities to meet the needs for material through transformational access through technologies, procedures, communities, and technologies.

Accessing Russian Culture Online: The scope of digitisation in museums across Russia

Melissa Terras

Although the rate and coverage of digitization throughout Europe is monitored and understood (Europeana, 2016; Minerva EC, 2016, Navarette 2015) there has been little work done on understanding the reach of digitization across Russia. In this paper, we build on previous work (Kizhner, Terras, Rumyantsev, 2016) by using Russian Ministry of Culture statistics to calculate the percentage of museum collections that have been digitized across Russia. We show regional variations and demonstrate that although many Russian museums have digitisation programs, this is not carried out to the same extent as across Europe. We suggest that studying non-European digitization practices can lead to further understanding of the digital canon upon which analysis of culture is based (Limb, 2007; Warwick et al, 2008; Price, 2009; Earhart, 2012).

Digital visual collections from national and regional museums can be a rich source of data for digital humanities but the first step in these studies might be to discover the existence of digital images on national levels. Do non-European digital collections exist? Do non-European museums provide the same amount of data as European museums? Is this amount equal for the centre of the country and for provinces? How many images are posted online?

This paper aims to find out the current scale of digitization in Russian museums. We discuss Russian digitization as an example of real life messy collection of data where the situation is hardly related to «post-modernist utopia» (Sartori 2016) or the wishful thinking of moving images across interfaces (Robinson, 2013; Kizhner, Stankevich, Terras, Rumyantsev 2016), all of them quite distant perspectives.

Starting from the 1970s, the rationale for museum digitisation practices in Russia was quite similar to that in many other countries. It was informed by a need for information and collection management so that museum objects would not be lost and were properly conserved (Navarette, 2014; Sher, 1983; Williams, 1987; Chenhall and Vance, 1987). Russian government policy related to that need from 2008 onwards was aimed at building The National Catalogue of Museum Objects posted online (Ministry of Culture of the Russian Federation, 2016) and currently including images for 1,2 million museum objects, 1,5% of total number of Russian museum objects (slightly over 80 million), and 2% of the collection of unique objects (about 60 million).

The National Catalogue is an initial access point in finding out the scale of museum digitization in various parts of the country including its remote regions. Our previous paper (Kizhner, Terras, Rumyantsev, 2016) demonstrated preliminary results of a survey estimating the percentage of digital images for Russian museum collections. The study also included web site exploration results on the percentage of museum collections posted online. However, it only covered 1,2% museums in the country for the percentage of digitized images and 6% for the images posted online and its results gave initial estimates.

The present paper studies the percentage of digital images through the statistical reports submitted to the Ministry of Culture from 2,367 museums in 2015. The annual statistical reports are mandatory for all museums reporting to local municipalities, regional administrations and the RF Ministry of Culture, in fact for all non-private and non-corporate museums. We provide the average results for the country and and the average results for its 8 major geographical regions.

Methodology

The data of the RF museums' statistical reports for 2015 were received from the RF Ministry of Culture in summer 2016. Museums return these mandatory reports in January and provide statistical data for the preceding year. The data were related to 2,635 museums from every region of the Russian Federation.

The data were received as an Excel spreadsheet from which the parts were removed that were not related to the digitization of museum objects and the data on galleries that were for temporary display and did not store any objects. This left us with 2,367 museums. The data in the spreadsheet were sorted on the total number of objects for every museum, the number of unique objects, the number of database records with digital images, and the number of images posted online.

Russian museum collections tend to consist of two parts: the main collection of unique objects and a smaller 'research collection' including duplicates and supporting documentation. While the total number of objects in Russian museum collections slightly exceed 80 million objects, the number of unique objects is 20 million fewer and equals 60 million objects. The results of statistical surveys obtained for the study reported the number of digitized objects as related to the total number of objects in a museum including their 'research collections'. This did not create a methodological problem when comparing the results with those from the Enumerate project which is a study of the outage of digitisation across Europe, funded by the European Union which happened between 2011 and 2015 (Europeana, 2016) where the survey asked to provide the percentage of digital images for museums' analogue collections.

The percentage of digitized objects and the percentage of objects with images posted online was calculated for each geographical region of the Russian Federation and mapped to show the differences. The total percentage for the country was also assessed.

Results

The percentage of digital images as related to the total number of museum objects across Russia was 13,5%. The percentage related to the number of objects in the main collection (roughly corresponding to the number of unique objects) was 18%.

The percentage of images posted online as related to the total number of objects was 1,5%, this figure was somewhat larger if compared with the number of objects in the main collection (2%).

An interesting and unexpected result was the difference between the scale of digitization in two major cities, Moscow and Saint Petersburg (Table 1). The percentage of objects with digital images was much higher than the average across Russia in Saint Petersburg and somewhat lower than the average in Moscow. The scale of digitization across major geographical regions varied between the minimum of 6% in the Far East and the maximum of 25% in the regions adjacent to Saint Petersburg (Figure 1, Table 1).

Interestingly, the percentage of images posted online was slightly lower than the average across Russia for museums in Moscow and twice lower than the average across Russia in Saint Petersburg (Table 2).

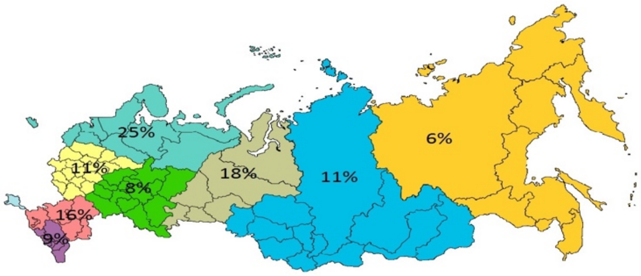

Figure 1. The percentage of the analogue collections digitally reproduced across geographical regions

Places	% as related to the total number of objects	% for the main collection (unique objects)
Saint Petersburg	36	44
Moscow	10	12
The average across Russia	13,5	18
Centre (Central Federal District)	11	14
North-West (North-Western Federal District)	25	33
Southern Federal District	16	23
Caucasus (North-Caucasian Federal District)	9	12
Volga Federal District	8	11
Ural Federal District	18	25
Siberian Federal District	11	16
Far Eastern Federal District	6	8

Table 1. The percentage of the analogue collections digitally reproduced in the museums of Saint Petersburg, Moscow, and across Russia

Places	% as related to the total number of objects	% for the main collection (unique objects)
Saint Petersburg	0,9	1,1
Moscow	1,2	1,5
The average across Russia	1,5	2

Table 2. The percentage of digital images posted online

Discussion

Our findings demonstrate that digital collections in Russian museums do exist across the country but we cannot say that their online display is representative enough to cover the culture, considering the variety in geography and ethnography.

We can roughly confirm our previous results on the percentage of digitized images (Kizhner, Terras, Rumyantsev, 2016) to be around 18% as our present data show the level of digitization to be in the range of 13,5 - 18%. However, our previous results might have a sampling bias as the museums answering the questions of the survey could be interested in digitization per se and work towards obtaining more financial and administrative support to keep it going. This might result in a higher percentage. Even so, the results of the present study can only demonstrate a range of digitization scale as the percentage of images related to the total number of objects may include a significant number of duplicates and supporting materials (e.g. library books).

This is not an obstacle to comparing our data with those from the Enumerate project 'which aimed to survey the extent of digitization across Europe' (Europeana, 2016) where the survey questions were about the percentage of the analogue collection digitally reproduced, but given the range of 13,5 - 18% we can say that the results for 2015 are much lower than the results of the Enumerate project for 2015 when the percentage of digitized collections in European museums was 31%. However, the results for Saint Petersburg collections are higher than the European average

(Table 1).

The percentage of images available online across Russia as related to the analogue collection is 1,5 - 2% which is lower than the percentage reported by the Enumerate project (24% of digital collections and 7,5% of European analogue collections). However, the Enumerate results included digital collections and digitally born objects available online, which complicates the comparison (Europeana, 2016).

Recent criticism of digitization without proper contribution to building knowledge in the humanities (Hitchcock, 2013, Gregory et al., 2016) requires developing these studies further towards exploring how Russian museum web sites arrange images for searching and browsing and developing projects discussing the issues of open access and digital canon.

This paper opens up the space for studying Russian digital collections on a national scale. It also reports on the results of looking at the scale of digitization for major geographical regions within Russia, and it will discuss the results of calculating simple correlations of digitization percentage with population density, the level of education, funding, and the number of museum goers in the regions. By doing so we can challenge the concept of the digital canon, and ask difficult questions regarding which types of culture are being digitized and made available worldwide.

Introduction

This paper explores the development of the *Personæ* tool (code available on Github), an interactive resource for exploring patterns of speeches by and mentions of characters in dramatic texts. Initially developed to examine works by Shakespeare, the tool has broad application to dramatic texts.

Visualising the frequency, extent, and position of dialogue relating to a particular character presents users with a simple and immediate measure of that character's prominence within the play. The *Personæ* tool enables users to select and visualise individual characters' involvement, producing a novel means of exploring large-scale structural, narrative, or character-focused patterns within the text.

The tool is intended to facilitate character-based analysis and reveal structural patterns at the scale of the play. The tool was conceived with exploratory potential in mind, and is designed to allow users to customise the visualisation according to their particular interests or to follow a more speculative and disinterested reading of the play's character-based features.

This deliberate aim emerged from the heuristic development process described below, and a desire to produce an extensible exploratory tool for dramatic texts. From an initial focus on using digital tools to visualise the tangling and disentangling of character names and identities in *The Comedy of Errors*, our interest broadened into exploring the potential for using character data to visualise larger structural and narrative patterns.

We were also motivated by the use of network analysis and visualisation for scholarship on Shakespearean and other literary texts, including work by Yose et al (2016), Grandjean (2015), Moretti (2011), and Stiller, et al. (2003). These analyses are similarly character-based and have yielded many interesting insights. But in the reduction of the textual data to nodes and edges (characters and their interactions), network analysis has obscured the temporal. The work of Xanthos, et al. (2016) maintains this temporal dimension, while exploring the dynamics of the character networks as they evolve. In contrast, by visualising the characters at the level of the play as a whole, we aim to preserve characters' locations within the space of the text, thereby enabling analysis of the dramatic time and structural duration of the play.

Tool Development

Tool development took part in two phases. First, the data was extracted and transformed into a suitable format. The user interface was then designed using an iterative process that enabled the exploration of various approaches to data presentation and interaction.

Data Preparation

The tool uses data contained in XML files provided in the New Variorum Shakespeare editions of *The Comedy of Errors* and *The Winter's Tale*.

Data was extracted using a custom-developed Python script which iterates through each play's XML file extracting character and name data, along with line number, scene and act identifiers. The data as output as JSON, which reduces the complexity of using it with the JavaScript-based user interface.

User Interface Design

The tool's web-based user interface (Figure 1) was developed using the open source Javascript library, D3 (Bostock et al, 2011). *Personæ* developed from a fixed and static visualisation of *The Comedy of Errors* to a more interactive and exploratory tool. In the heuristic spirit of the tool itself, we describe here its various iterations, the stages of its development, and the motivations for various changes to its design and functionality throughout the process.

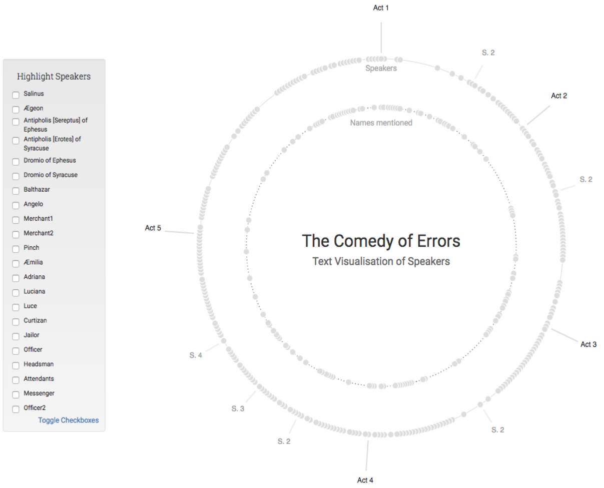

Figure 1: *Personæ* Character Visualisation Interface - From the First to the Second Iteration

Personæ's focus on character and temporal visualisation is present in the first iteration of the tool (Figure 2). Speeches and mentions are plotted along a timeline, with a tabular view switching between the five acts of the play. All speeches and mentions are colour-coded, resulting in some interesting patterns and densities at certain parts of the text, but lacking the facility for isolating chosen characters. In addition, the tabular view of the five acts lacked the desired holistic view of the entire play.

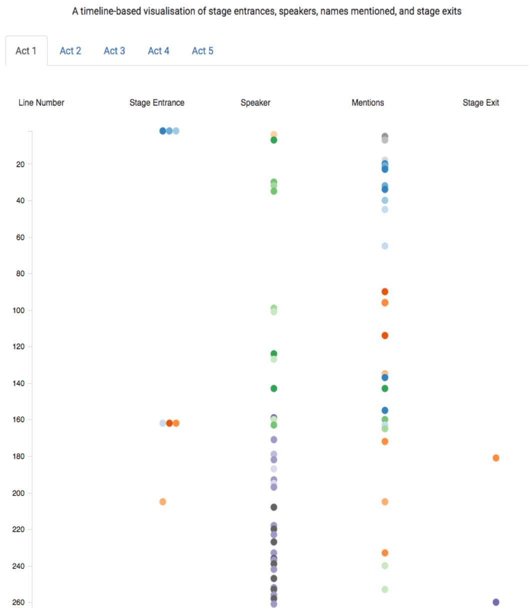

Figure 2: First iteration design

Expanding the Second Iteration

The second iteration of the tool adopted the circular layout of the tool to plot character involvement across the entire play, as shown in Figure 3. At this point, the tool was still static, and its focus on the two pairs of twin characters in *The Comedy of Errors* represented a desire to deploy visualisation for a particular exploratory purpose. The play operates on the basis of identity and confusion, as Antipholus and Dromio of Syracuse are mistaken for their Ephesian counterparts, and vice versa. Our aim was to plot the speeches of these four characters to see if the visualisation revealed any insights into how the identity question was introduced and managed at a structural level.

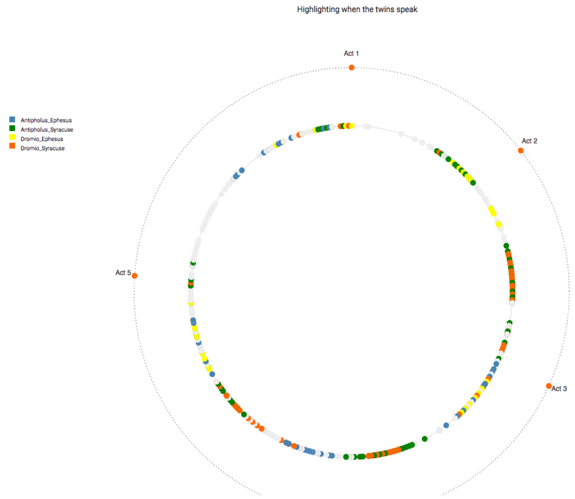

Figure 3: Second iteration design

Indeed, the visualisation presents several clustered scenes of engagement between the pairs of twins through which various errors and misunderstandings are played out. The tell-tale single appearance of Dromio of Syracuse's orange marker in Act 1, Scene 2 precisely represents the beginnings of the error and confusion: “What now? How chance thou art returned so soon?”

An additional avenue of exploration in the second iteration of the tool was the geographical mapping of locations mentioned in the play. *The Comedy of Errors* is known for including the only mention of America in Shakespeare’s plays, among several other placenames in its text. In some respects, this visualisation gives a false impression of *The Comedy of Errors* as a worldly play. While eighteen locations are mentioned in the text, several of these are ironically located by Dromio of Syracuse on Nell the kitchen-maid’s body, because “she is sphericall, like a globe: I could find out / Countries in her” (Act 3, Scene 2).

The final interface

As useful as this view of the play proved, we felt at this point that a more dynamic and interactive interface was required to allow users to test hypotheses like our own, or to undertake more exploratory and experimental visualisations of the data, as illustrated in Figure 4. The circular layout was retained, as it provided a useful method of presenting the play as a whole, while maintaining the temporal dimension of the character interactions. The character-selection menu and the scene-divisions in the outer ring were thus added in the final stage of development.

Figure 4: Final interface design

Also added were visualisations of higher level metrics to illustrate the number of times a character speaks, and the number of lines they speak.

Conclusion

A major part of the tool’s value is its extensibility. It may be used to create character visualisations for any play which is XML-encoded according to quite minimal specifications, and offer the opportunity to undertake comparative analysis of structural, narrative, and character-based patterns in different plays. Indeed, while the development of the tool focused on *The Comedy of Errors,* a similar visualisation of *The Winter’s Tale* (Figure 5) was generated from New Variorum Shakespeare XML files with no revision to our code.

Figure 5: Visualisation of The Winter’s Tale

The trajectory of *Personæ*’s development from fixity to interactivity represents a conclusion that we drew in the course of this project: that a visualisation tool developed for a particular purpose need not be confined to its use for that objective alone. The modular and open-source principles of software development have contributed to a rich and fruitful habit of sharing within the field of Digital Humanities, and we hope that others will build upon the tool that we have developed here.

Indeed, we have plans for further developments and improvements to *Personæ*. Working towards a tool which will enable structural and thematic comparison of the thirty-six plays in the First Folio, the next phase will test for structural correlations in a thematic grouping of five additional Shakespearean plays. This development will strengthen *Personæ*’s potential for generating insights into macro-level structural analysis of dramatic texts, while testing its technical extensibility by incorporating XML files from another source, [The Bodleian First Folio.]

Introduction

The Russian flu 1889-1893 epidemic reached Europe from the East in November and December of 1889 and spread over the whole globe in the space of a few months. It was one of the first epidemics of influenza that occurred during the period of the rapid development of bacteriology. In addition, it was the first ever epidemic that was publicly and intensively narrated in the developing daily press, especially those published in German located in Germany and Austria (Mirosławska et al., 2013). However, as stated in (Valtat et al., 2011), very limited information about the epidemiology of this influenza has been found, which was based on materials published in English. While a large amount of news about the flu was published in German, it is hard to find a study on the epidemic based on German documents. These motivate our goal in this work, which is to build a framework from German materials to support research community getting more insights into the disease. Our framework consists of different components including data collection and cleaning, corpus creation, and associated tools for analysis. The framework is pictorially shown in Figure 1.

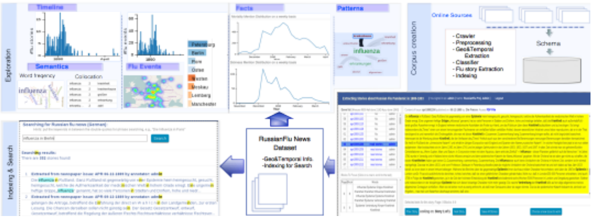

Figure 1. Russian flu exploration framework

Related work

There is limited information about the epidemiology of the Russian flu epidemic 1889-1893. In (Mirosławska et al., 2013), the authors conducted an analysis to examine the impact of the epidemic in 14 cities in Europe. Their results showed that the epidemic spread quickly from Saint Petersburg, Russia to other parts of Europe with a speed of around 400 km/week and reached the American continent only 70 days after the original peak in Saint Petersburg. In addition, some detailed information about case fatality ratio and the median basic reproduction was given also. However, their work was based on reports of only two local daily newspapers in Poznań, which implies some uncertainty due to the lack of data coverage. Valleron et al., 2010 presented a case study on the transmissibility and geographic spread of the Russian flu. A similar approach was followed by Valtat et al., 2011 to examine the age distribution of the affected people and the mortality rate of this flu event. In a recent study, Ewing et al., 2016 collected contemporary reports and explored a digital humanities approach to interpret information dissemination regarding this particular epidemic. The limitations common to all of these studies are the heterogeneity and lack of coverage of data used.

Table 1: Keywords used to collect high recall collection of newspaper issues containing stories about influenza epidemic

Data collection

Data used in this work was collected from the Austrian Newspapers Online (ANNO) repository. ANNO contains almost all issues from many newspapers in Austria and Germany during the time the Russian flu epidemic took place. The data are accessible in both scanned PDF and OCR formats. These are appropriate for our goal in terms of extracting Russian flu related stories from noisy OCR text and checking against the scanned PDF content for validity. To establish the data collection, the keywords listed in Table 1 (along with some misspelt variations of keywords, which were included due to OCR misrecognition) were used to search the ANNO repository The search query was constrained by the time interval from 1889 to 1893. After preprocessing the search results we obtained 4,806 issues, which become the candidates to extract stories about the Russian flu.

Noise reduction

Due to the low quality of the scanned images of newspaper issues, a lot of noise is present in the corresponding OCR texts. The word error rate (WER) computed on sample texts is around 18.9%. Our goals here were to remove noise and correct misrecognized words as much as possible but at the same time manage keep the language as it was so that the derived corpus pertains its historical perspective. It is noted that modern German is rather different in writing and usage of many words due to the language's evolution. To cope with these issues, we adopted a snapshot of the Google-2-gram dataset for German from 1885 to 1895. The dataset was used to train our bigram-based model for word segmentation and spell checking. After running the model, the word error rate was reduced to 5.5%.

Text block classification

A difficult challenge for the task of extracting complete stories is that recognized OCR text blocks are very often not aligned in the same order as they were in the original image of an issue. Our approach was to automatically pre-classify OCR text blocks to identify the ones that are more likely part of some flu-related stories. Then we developed a tool to effectively help annotators extract complete Russian flu stories. For this, we adopted the KL-divergence based technique developed in (Schneider, 2004) to build a classifier. The model was trained with 245 OCR text paragraphs and obtained recall of 81.5% and precision of 68.6%. Basically, the output of the classifier can be used to help annotators start working on an issue by looking at suggested text blocks first, from which they can then select paragraphs that are part of the same story.

Extraction tool

After completing the high-recall automatic pre-extraction, we implemented a Web-based tool for annotators to help build our corpus collaboratively. The main GUI of our tool is shown in Figure 2. After having annotators work through the whole collection, we obtained a corpus of 639 news articles about Russian flu from 42 newspapers, identified with 85.7% agreement between annotators.

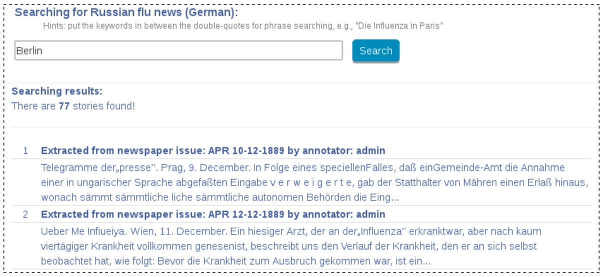
Figure 2. Main GUI of our tool for Russian flu story extraction

Geo and temporal information extraction

Given that location and time are helpful features for exploring the development of the epidemic, we extracted and normalized geographic names and temporal expressions occurring in the corpus. For geographic names, the Geodict tool created by Pete Warden (2011) was adapted to work with country and city names in German. HeidelTime (Strötgen and Gertz, 2013) was used for temporal information extraction and normalization.

Indexing and search engine

We created a search engine on the corpus to support research community in searching for information. The searching GUI is shown in Figure 3.



Searching for Russian flu news (German):

Hints: put the keywords in between the double-quotes for phrase searching, e.g., "Die Influenza in Paris"

Searching results:

There are **77** stories found!

Figure 3. Russian flu story searching module

Exploration tools and sample results

We provided associated tools along with the corpus. The corpus timeline provides statistics on the number of stories in the corpus across time and news outlet. In addition, it provides interactive visualization. As an example shown in Figure 4, during the peak time in late December 1889 and January 1890, extensive news about the influenza was published.

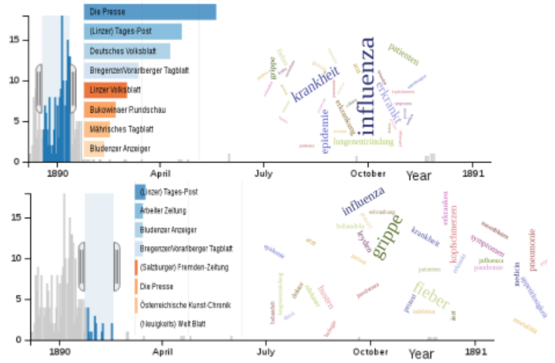

Figure 4. Press attention on the flu and topic changes over time

Newspapers were trying to narrate the outbreak as fast as possible. Words that appear significantly in the stories include *influenza*, *epidemic*, *krankheit (disease)* and *erkrankt (sick)*. A short time after this peak period, fewer reports were published about the outbreak of the flu and communities started discussing the treatment more. Names of doctors appearing in the news (e.g., Leyden, Proust) together with words describing symptoms such as *fieber (fever)*, *kopfschmerzen (headache)*, *appetitlosigkeit (anorexia)*. Furthermore, by exploring word collocations one can find even more interesting information. Figure 5 shows a frequent pattern of word collocation describing the influenza. The words *heute (today)* and *gestern (yesterday)* indicate that news about the flu is updated every day*; and* the word *jänner (January)* implies that the flu outbreaks happened during winter.

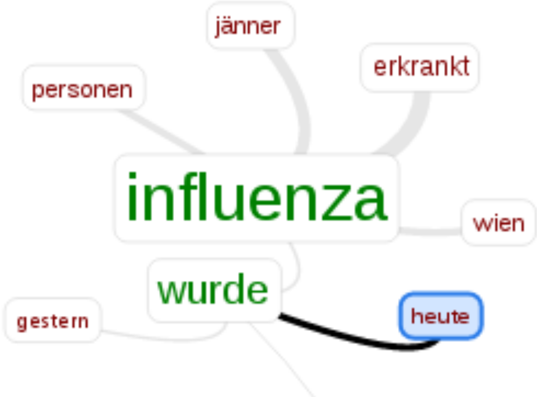

Figure 5: A frequent pattern of word collocation extracted from our corpus

Figure 6 presents the co-occurrences of three words *infuenza, erkrankt, and london* over time. It shows a similar trending pattern of the words *infuenza* and *erkrankt* being used to note about the flu. In addition, one can observe that the peak time of the flu in London was from late December 1889 to early January 1890 as indicated in (Honigsbaum, 2010; Goff, 2011). This suggests that the temporal distribution of terms can give us more insights into the evolution of the epidemic.

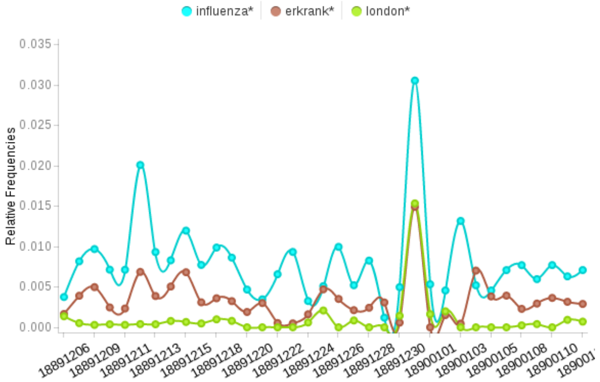

Figure 6: Similar trending pattern of the two words influenza and erkrankt, and the peak time of the flu in London

The framework also supports studying the evolution of the flu over time and geographic regions. We employed the method introduced in (Abdelhaq et al., 2013) for localized event detection. Figure 7 shows three snapshots describing the development of the epidemic over cities in Europe during the peak time from late November 1889 to January 1890.

Summary

We have introduced a framework for research communities to explore the historical Russian flu 1889-1893 from German newspapers. We developed a tool for collaborative annotators to help build our corpus. We further presented some interesting insights that we achieved from analyzing articles in the corpus. By making the corpus and associated tools available, we provide useful contributions to the community in support of conducting studies on influenza epidemics and evaluating temporal IR models.

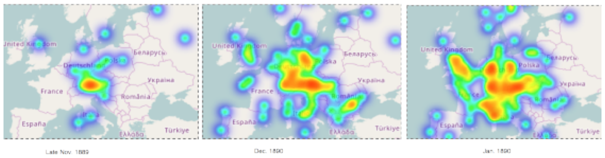

Figure 7. Evolution of the Russian flu over geographic regions during its peak time

Introduction

The *Willa Cather Archive (WCA)* at the University of Nebraska-Lincoln (UNL) is currently working on transcription and annotation of 1500 letters to be released in 2018. As editors will write several thousand annotations, the workflow logistics are complicated. Annotonia (a portmanteau of "annotation" and *My Ántonia*, a 1918 Willa Cather novel) is a solution developed within the Center for Digital Research in Humanities (CDRH) that allows editors to write annotations directly on letters in a browser and insert those annotations into Text Encoding Initiative (TEI) XML files. Multiple editors review annotations, track letters' annotation statuses, and generate a new TEI file incorporating the annotations, avoiding having to manually edit each file. Annotonia utilizes both pre-existing, customized open source software and new software developed for this project. This paper describes the difficulties faced, the workflow of Annotonia, and its prospects for future annotation work.

The challenge

The *Complete Letters of Willa Cather* is a National Endowment for the Humanities-funded project to publish a digital, fully annotated edition of the letters of Willa Cather, a 20th century American novelist. The project includes student editorial assistants, staff, and faculty both at UNL and working remotely. Because of differences in locale, technical abilities, and Cather-related expertise, a solution was sought for drafting, revising, and encoding letter-specific annotations that would fit the skillsets of all collaborators.

The *WCA* has two types of annotations: authority files and letter-specific information. Editors skilled with TEI XML curate and encode people, places, and works shared across the corpus into authority files. Letter-specific annotations are more challenging to manage as they are written by a wider group of scholars, many unfamiliar with encoding XML. Editors previously used a cumbersome process of pasting documents into Word files, sharing them for annotation, and laboriously copying received annotations back into the XML. This tedious process introduced errors and was deemed unsustainable for the large number of anticipated letter-specific annotations.

With these difficulties in mind, *WCA* editors collaborated with CDRH developers to envision tools that would allow viewing the content of letters with all associated materials; writing letter-specific annotations that might include images, links, or other materials; and exporting finalized versions of these annotations as TEI XML. Editors also identified the need to view annotations that had already been written so information contained in them would not be repeated.

Project requirements

- Display letters via HTML with existing controlled vocabulary annotations for people, places, and works.
- Provide an interface where editors can browse, edit, approve, and flag annotations.
- Export annotations to their preservation format, TEI P5 XML.
- Insert <ref> tags into the TEI XML corresponding to ID's in the annotation file above.

Existing software review

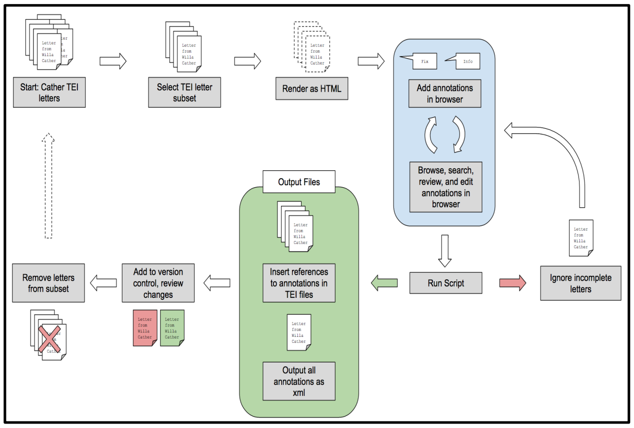
Before building Annotonia, we looked at existing technologies and methods for annotating HTML. Web-based annotation is not a new concept, by any means. The value of annotating HTML has long been recognized for its collaborative strengths, allowing users to identify errors, review, comment on, and bookmark documents (W3C Digital Publishing Interest Group, 2014). The W3C currently has a Web Annotation Working Group dedicated to creating specifications for "interoperable, sharable, distributed Web annotation architecture" (W3C Web Annotation Working Group, 2017; Web Annotation Data Model, 2017).

Most annotation software reviewed was not suitable for the project. Many existing solutions (such as Annotation Studio, Recogito2, and Editor's Notes) did not allow in place annotation, instead requiring one to upload documents to their system. This would strip out the existing annotations, making work more difficult for editors. Some (such as PundIT) were not fully open source. Others (Such as Hypothes.is) were developed for public input and would require stripping out many features for our needs. Other problems encountered included installation roadblocks, lack of maintenance, and poor documentation. Importantly, our requirement of exporting annotations and embedding them into TEI documents was not supported by any existing systems.

With these considerations, programmers chose to work with Annotator and its back end complement, Annotator Store, because the software interacts through an API and uses XPaths for pinpointing annotations' locations (Open Knowledge Foundation, 2016a; 2016b). Annotator proved to be easy to install and extend with community plugins, such as rich text editing, keyword tagging, and filtering. Annotator Store's use of Elasticsearch reinforced the decision to use it, as Elasticsearch is widely used and receives generous community development and support. Annotator deals only with the annotation part of the requirement and not categorizing or workflow, which had to be developed in-house.

Annotonia: the solution

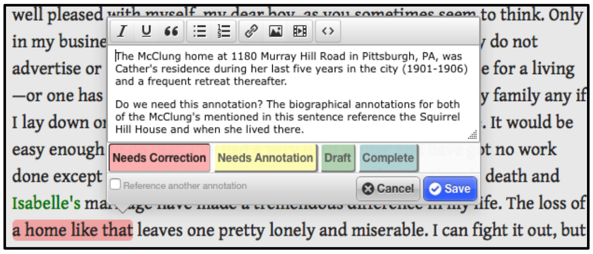
The first step was simply to display the letters' TEI XML in a browser in a way that minimally rearranged the structure of the documents. TEI Boilerplate uses browser XSLT capabilities to create an HTML/TEI hybrid representation of TEI documents with small alterations for links, images, and other elements (Walsh et al. 2013). Boilerplate was therefore useful for constructing HTML from documents, while allowing for TEI files to be added and removed quickly from the site structure and workflow.



Start: Cather TEI letters
Select TEI letter subset
Render as HTML
Fix
Info
Add annotations in browser
Browse, search, review, and edit annotations in browser
Run Script
Ignore incomplete letters
Output Files
Insert references to annotations in TEI files
Output all annotations as xml
Add to version control, review changes
Remove letters from subset
Letter from Willa Cather

Figure 1: The Annotonia workflow for a single batch of letters

In order to be able to annotate the documents displayed using TEI Boilerplate, programmers embedded Annotator in the web page and modified it so it had suitable options for the *WCA* editors. These included stripping out some of the text editing capabilities and adding workflow-specific options.



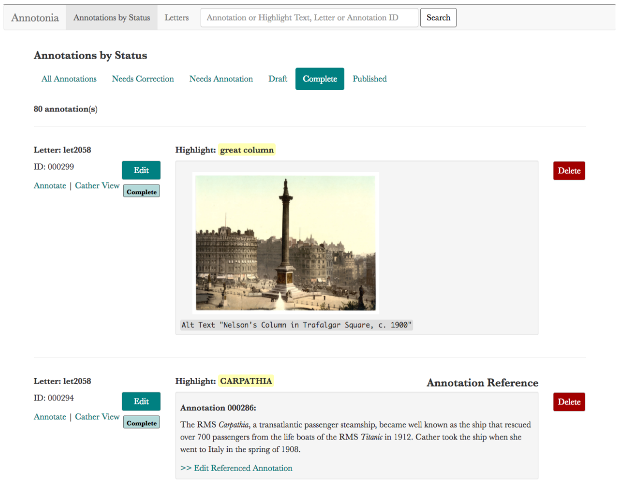
well pleased with myself, my dear boy, as you sometimes seem to think. Only
in my busine ... y do not
advertise or ... e for a living
—or one has ... y family any if
I lay down o ... . It would be
easy enough ... t no work
done except ... death and
Isabelle's ma ... life. The loss of
a home like that leaves one pretty lonely and miserable. I can fight it out, but

The McClung home at 1180 Murray Hill Road in Pittsburgh, PA, was Cather's residence during her last five years in the city (1901-1906) and a frequent retreat thereafter.

Do we need this annotation? The biographical annotations for both of the McClung's mentioned in this sentence reference the Squirrel Hill House and when she lived there.

Figure 2: An example of creating and categorizing an annotation with Annotonia

Annotator does not include an interface for searching, browsing, and editing all of the annotations from the Annotator Store. PHP pages were written to provide these capabilities.



Annotations by Status

80 annotation(s)

Letter: let2058
ID: 000299

Highlight: great column

Alt Text "Nelson's Column in Trafalgar Square, c. 1900"

Letter: let2058
ID: 000294

Highlight: CARPATHIA

Annotation 000286:

The RMS *Carpathia*, a transatlantic passenger steamship, became well known as the ship that rescued over 700 passengers from the life boats of the RMS *Titanic* in 1912. Cather took the ship when she went to Italy in the spring of 1908.

Figure 3: Annotation review page including an annotation with an image and a referenced annotation

The last requirement for Annotonia was a conversion script that inserts annotation references into TEI documents while exporting an authority file containing the annotations. The conversion script takes a subset of XML files, queries the Annotator Store API, adds tags for annotations based on XPaths, and outputs a list of possibly incorrect insertions that require review.

Use and extension

The collection of new scripts and open source software comprising Annotonia has been able to handle the workflow requirements of the *WCA's* letter annotations, though there is room for improvement. The areas that require the most attention are the rendering of TEI in HTML and the scripted editing of TEI files. TEI Boilerplate necessarily alters the TEI in order to mimic the behavior of HTML links and images, which means that occasionally the location of an annotation in the HTML view is difficult to match up programmatically due to differing XPaths.

A new alternative to Boilerplate, CETEIcean, which promises to preserve "the full structure and information from your TEI data model," may be one possibility to address this problem (Cayless and Viglianti, 2016). Programmers would need to evaluate how easily it can be incorporated into the Annotonia workflow, as well as the ability to load the Annotator JavaScript libraries in the page.

Some aspects of the Annotonia code base are tailored for use only with TEI Boilerplate display and *WCA* file naming conventions. These functions would have to be generalized to make Annotonia easier to integrate with other tools and projects. Meanwhile, the Annotator community continues to improve the software. A new version is forthcoming which includes modifications to enhance the experience of creating, saving, and updating the highlighting of HTML content. When this version of Annotator is released, it may require some reworking of existing customizations, but updating Annotonia to incorporate its new features will support a broader variety of projects.

Reception

The *WCA* began using Annotonia in September 2016. Guidelines and instructional videos demonstrating Annotonia's functions have alleviated difficulties from the varying technical skills of editors. Although still in the beginning stages of annotating individual letters, the tool works well for collaborating on, drafting, and revising annotations. Editors have estimated that each annotation automatically handled saves around 5 minutes of time, so the potential time savings is several months of work. Through an iterative process, improvements have been added as users uncover inefficiencies and provide feedback. By 2018, several thousand annotations will be created with Annotonia and published with the complete letters on the *WCA*.

Further applications

A frequent difficulty for digital archival projects is efficiently proofreading and annotating texts. In the CDRH, these workflows on other projects resemble the *WCA*'s old process of marking up Word documents, or, worse yet, printing out entire websites and annotating by hand. Designing solutions by combining open source software with well documented, configurable scripts and workflows has proven to be effective in providing flexibility to cover a variety of needs. As we apply this method to extending and generalizing Annotonia for other projects like the *Walt Whitman Archive* and *The William F. Cody Archive*, we will further refine deployment and documentation.

The PHP and conversion components of Annotonia have been published ("Annotonia Status" and "Annotonia Converter", and the customized pieces of existing software will be published soon. Full publication of Annotonia will involve further documentation and testing. It is the hope of the Annotonia team that this tool will not only prove to be useful internally, but will provide inspiration to other text based editions seeking to automate annotation processes.

Verifying the Authorship of Saikaku Ihara's Arashi ha Mujyō Monogatari in Early Modern Japanese Literature: A Quantitative Approach

Ayaka Uesaka
auesaka@mail.doshisha.ac.jp
Organization for Research Initiatives and Development
Doshisha University, Japan

Introduction

This study focuses on *Arashi ha Mujyō Monogatari ("The Tale of Transient Popular Kabuki Actor Arashi's Life"; 1688)*, a novel from the early modern Japanese literature, written by Saikaku Ihara (1642–93). It is a first work of a Kabuki actor's life in Japan (Kabuki is a traditional stage arts performed exclusively by male actors with the accompaniment of live music and songs). Then we will examine the "authorship problem" in Saikaku's works using the tools of quantitative analysis.

Saikaku was a national author whose novels were published in 17th century. Saikaku's works are known for their significance for developing Japanese contemporary novels. One recent hypothesis has stated that he wrote twenty-four novels, however, it remained unclear which works were really written by Saikaku except *Kōshoku ichidai otoko ("The Life of an Amorous Man"; 1682)*, *Shōen Ōkagami ("The Great*

Mirror of Female Beauty"; 1684), Kōshoku ichidai onna ("The Life of an Amorous Woman"; 1686), Kōshoku gonin onna ("Love Stories about Five Women"; 1686). Although the study of his works has continued, these fundamental doubts about his authorship remain.

Meanwhile, the potential of quantitative analysis of textual data and the related field of the digital humanities have also dramatically advanced. However, quantitative analysis of Japanese classical works has been behind. It has been a problem due to complications regarding development of morphological analysis software and also delayed digitalization of Japanese classical works.

Previous Studies

Found by Noma in 1941

Noma found and introduced *Arashi ha Mujyō Monogatari* in 1941. He mentioned that the novel was actually written by Saikaku, for the following reasons (Noma, 1941 and 1964). (1) The handwriting of the novel belongs to Saikaku; and (2) He found a similar writing error in *Arashi ha Mujyō Monogatari* and Saikaku's work.

Arguments for Saikaku's authorship

The handwriting is not crucial in deciding if they are Saikaku's novels. According to Emoto *et al.* (1996), among his twenty-four novels, the handwriting of nineteen works does not belong to Saikaku. Moreover, Saikaku made a fair copy of other writer's draft such as *Kindai Yasa Inja ("The story of a hermit"; 1686)* by Kyōsen Sairoken (? -?) and *Shin Yoshiwara Tsurezure ("The book of commentary on the licensed quarters of a certain area"; 1689)* by Sutewaka Isogai (? -?).Mori (1955) has argued that Saikaku's novels are an apocryphal work mainly written by Dansui Hōjō (1663-1711) except *Kōshoku ichidai otoko.*

As he gained a national audience, Saikaku was pressured to write on demand and in great volume. At first he wrote only one or two novels a year, however in the two years from 1687 to 1688 he published twelve books, with a total of sixty-two volumes. Saikaku's style and approach also changed at this point (Shirane, 2004).

It is possible that Saikaku had some assistance (Nakamura,1969). *Arashi ha Mujyō Monogatari* was published in this period. Moreover, *Arashi ha Mujyō Monogatari* does not have a preface, epilogue, signature, namely it is not specified that it was written by Saikaku. Despite the authorship problem of *Arashi ha Mujyō Monogatari* remains unanswered, little work has been done about it. For that reason, this study re-examines the authorship of *Arashi ha Mujyō Monogatari* using a quantitative approach.

Databases

Database of Saikaku's Works

First, we digitized all the text of 120 works of Saikaku (24 novels, 80 poem books, etc.) based on the first edition of each works (see Figure 1). Second, Since Japanese sentences are not separated by spaces, we built the rule with early modern Japanese researchers, who were editors of *Shinpen Saikaku Zenshu ("The new complete works of Saikaku")*. Finally, based on this rule, we added spaces between the words in all of the sentences. In addition, the grammatical categories' information was added. According to our database, there are 710,355 words contained in his 120 works.

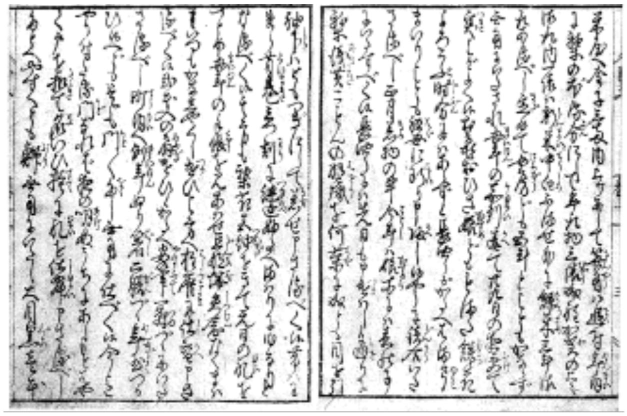

Figure 1: Saikaku's publication

Database of Dansui's Works

We also made the database of Dansui's novels Shikidō Ōtuzumi ("The Great Drum of Love"; 1687), Chuya yōjin ki ("The Night and Day of Precaution"; 1707) and Budō hariai Ōkagami ("The Great Mirror of Martial Arts"; 1709), using same methods and rules of Saikaku's database. According to our database, there are 53,838 words contained in these works. The next section considers the doubts about the authorship problem of Arashi ha Mujyō Monogatari.

Analysis and Results

In our previous studies, we have analyzed Saikaku and Dansui's novels, and have clarified the following two points by extracting their writing style using principal component analysis (PCA) and cluster analysis (hierarchical clustering): (1) A comparison of the Saikaku and Dansui's novels showed ten prominent features: the grammatical categories, words, nouns, particles, verbs, adjectives, adverbs, adnominal adjectives, grammatical categories bigrams and particle bigrams (Uesaka, 2015, 2016); and (2) Using these features, we analyzed Saikaku's four posthumous novels (many researchers have raised questions about the authorship, because these novels were edited and published by Dansui after Saikaku's death). We found these four posthumous works indicated same features of Saikaku's novel, therefore we concluded that these four posthumous novels belonged to Saikaku (Uesaka・Murakami,2015ab, Uesaka, 2016).

In this study, we compared *Arashi ha Mujyō Monogatari* to Saikaku and Dansui, as authenticated novels of them (see Table 1) by ten prominent features using PCA and cluster analysis to see the differences in each novels. The analysis revealed differences of writing style between *Arashi ha Mujyō Monogatari*, Saikaku and Dansui.

Saikaku's novels	*Kōshoku ichidai otoko, Shōen Ōkagami, Kōshoku ichidai otnna* and *Kōshoku gonin onna*
Dansui's novels	*Shikidou otsuzumi, Chuya youjin ki and Budou hariai okagami*

Table 1: The authenticated novels of Saikaku and Dansui

We conducted PCA with correlation matrix and these novels fall into three groups: Saikaku, Dansui and *Arashi ha Mujyō Monogatari* (see Figure 2). Furthermore, we conducted a cluster analysis. There also appears to be a considerable difference among *Arashi ha Mujyō Monogatari*, Saikaku and Dansui's novels. When calculating distances between each novels, we normalized the frequency of each words, and used the Kullback–Leibler divergence and the algorithm from the Ward method. Furthermore, we obtained similar result of the other nine features: the grammatical categories, words, nouns, particles, verbs, adjectives, adverbs, adnominal adjectives and particle bigrams.

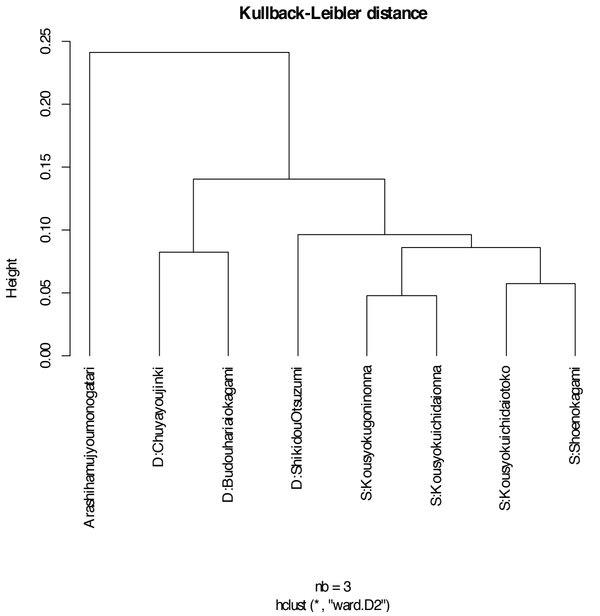

Figure 2: PCA results for grammatical categories bigrams

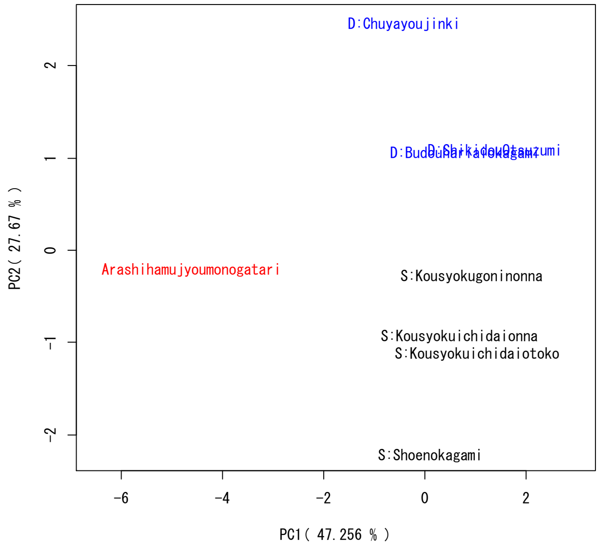

Figure 3: Cluster analysis results for grammatical categories bigrams

Discussion and Conclusion

When comparing ten prominent features using PCA and cluster analysis, we found that *Arashi ha Mujyō Monogatari* was significantly different from Saikaku and Dansui's works. A number of features indicate that *Arashi ha Mujyō Monogatari* is not Saikaku and Dansui. In order to clarify *Arashi ha Mujyō Monogatari*'s author, we need to conduct more detailed analysis. It is necessary to add the data of other writers with the possibility of the author of *Arashi ha Mujyō Monogatari*, for example, Kiseki Ejima(1666-1735) and Ichirōemon Nishimura(?-1969). We have been building the database of these author's 13 novels, and we will do comparisons in the future study.

Acknowledgements

We would like to thank Professor Masakatsu Murakami, Professor Hidekazu Banno and Professor Takayuki Mizutani for their help on our research. This work was mainly supported by the Japanese Society for the Promotion of Science (JSPS) Grant-in-Aid for Research Activity Start-up(16H07328).

LIMORIES: Expanding Access to Local Histories and Memories with Computational Aids in the Indian Context

Lakshmi Valsalakumari
lakshmi.valsala@research.iiit.ac.in
Centre for Exact Humanities, IIIT-Hyderabad, India

Introduction

> "It is memory that makes your identity. If your memory be lost, how will you be the same man?"
> – Voltaire

India is well-known for its diversity of culture. Like its languages, its localities too have evolved through the ages, each abounding in markers that talk of its past - externalized, at times, in monuments or historical artefacts, but captured even more eloquently, perhaps, in the customs, rituals, traditions, songs, arts and crafts, language and the daily life of its people.

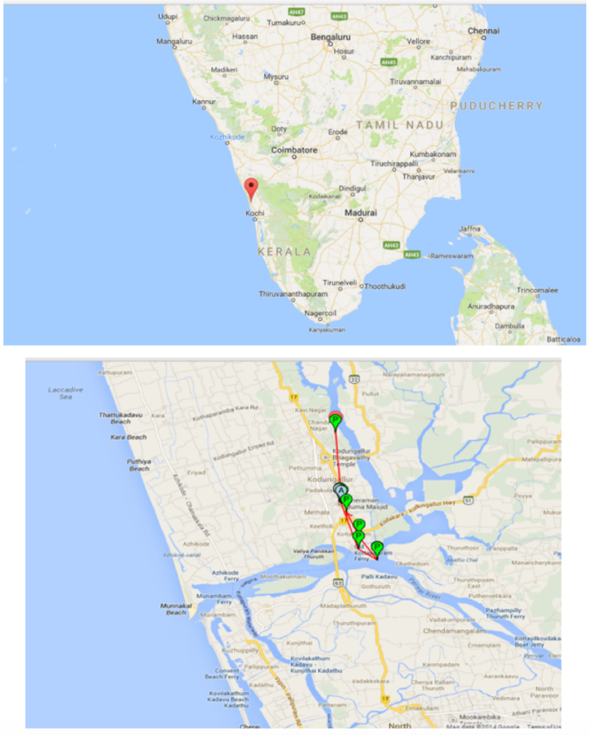
Yet, as India modernizes, this very diversity that has been a hallmark of the civilization is under threat. The homogenizing effects of globalization are all too visible as one traverses the country today; as cities and towns, that look more and more alike, expand to swallow up rural suburbs, and people give up traditional vocations and lifestyles to join the global workforce (Varghese, 2013). While this is reported positively in economic circles, and is counted as a welcoming sign of the increasing prosperity of vast majorities of the Indian populace, an unfortunate side-effect, concurrently felt, is the loss of the sense of uniqueness, traditionally associated with each Indian locality. This has led to growing pangs, across significant cross-sections of the society, about a gnawing loss of cultural identity – a concern not restricted to India or Indians (Khair, 2016).

Limories is a work-in-progress system that attempts to capture the distinctiveness and uniqueness of a locality from its people. Limories believes that the sense of past of a locality, unique to each locality, inheres in each and every individual associated with it, and is special and key to understanding and appreciating that locality wholly and in full. Limories attempts to do this by sourcing the externalized memories from the people themselves; collating, curating and presenting them - using open-source technologies. Goals include coming up with a curation framework, tools, standards and best practices, practical and relevant to the Indian context, which can be applied across localities. The generalization is a particular challenge, given the emphasis on the 'vaiseshik' – the 'distinctive' of each locality, aimed to be captured. And indeed, how one applies the general to the particular, remains a key differentiator between sciences and humanities (Singh, 2003).

This short paper will describe the pilot site where Limories was attempted, and the results thereof. It will also outline challenges being worked out, and the overall roadmap.

The pilot site

Kodungallur is a quiet town in Kerala, situated near the mouth of where one of the two arms of the perennial Periyar River empties itself into the Arabian Sea.



Source: Google Maps

Known during the colonial period as Cranganore, Kodungallur was earlier famous as capital to the Perumals of Kerala during the formative 9th-12th centuries CE of Kerala history and culture (Narayanan, 1972).

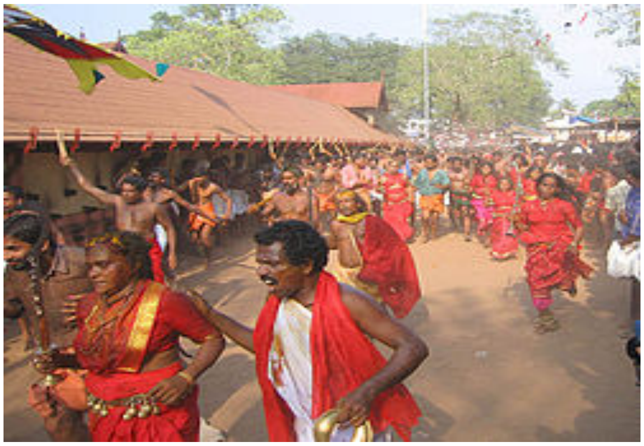
Until recently, Kodungallur was considered to be the ancient port of Muziris, described in Greco-Roman texts, such as the 'Periplus of the Erythrean Sea' (Casson, 1989), and referred to as Muchiri, in Tamil Sangam poetry. While recent research points towards Pattanam, a place about 9 km upstream from Kodungallur, as a probable contender for the exact location of the ancient port (Cherian et al., 2014), even today, the reputation of Kodungallur as the entry point of multiple religions – Christianity, Judaism and Islam, into the Indian sub-continent from across the seas, is proudly cherished by the people of the locality.

The Cheraman Perumal Mosque in Kodungallur, probably the earliest in India, its architecture providing testimony to the region's syncretic past (Picture: Own)

Among the various temples that dot the town, the one that attracts the most devotees today, almost eponymous with the town, is the Kodungallur Amma temple – dedicated to the Mother Goddess – the Mother of Kodungallur.

The Kodungallur Bhagavathy Temple or Sree Kurumba Kaavu (Picture: Own)

The temple, or 'kaavu' (sacred grove), has, in public perception, a kind of notoriety associated with its annual 'Bharani' festival – gained from the festival's rather peculiar rituals. During the Bharani period, devotees in large numbers throng to the temple from distant areas, clad in vivid red, clanging sickles in their hands, singing profane songs. The culminating 'Kaavu theendal' ritual of the festival is widely commented on and studied.



The Kaavu Theendal (Source: Wikipedia)

It was this site that the noted local historian, late Dr.N.M. Nampoothiri, former Dean of the Centre for Heritage Studies, Kerala, suggested to this researcher as a pilot. Over the years of 2014/2015, as I started gathering the history and lore related to Kodungallur and the temple from various sources, it was the Bharani rituals that stood out and piqued one's curiosity the most - with its peculiarity, and yet, its unquestionable popularity that drew faithful crowds.

'Who' were the people who came for this festival? What drew them? As I went through the articles written about the festival, I saw that theorizations ranged from it having been a practice instituted to drive out Buddhist monks, to the shrine being the memorial of the Silappathikaram protagonist Kannaki. But none of those served to explain the relevance of the festival today - why it continued to thrive and attract people. What also struck one was the contrast between the general perceptions about the festival, and the attitude of those intimately associated with the locality and the festival.

In Limories, I have presented the Kodungallur Bharani, as I saw and experienced it, during 2014 and 2015. My emphasis has not so much been on the past, as on the present, as I tried to capture what had fascinated me - the continuities and connections the locale and the festival had nurtured and preserved, across time and place.

The presentation – as a photo–narrative

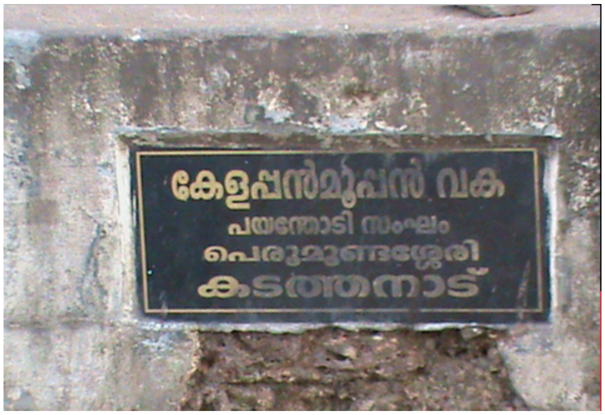
A photo-narrative was decided on as the best approach to convey the richness of the festival, chosen after abandoning other text-based approaches.

The photo-narrative had the advantage of being more accessible – both to the people I had sourced the content from, and to wider audiences.

Most Bharani participants speak Malayalam or Tamil. The crowd is mixed – literate and illiterate. While youngsters are familiar with English, the older people are not.

As I tried out various approaches to present my content, I realized that the photographs were the most evocative of all, and that weaving the narrative around those would help bridge literacy and language barriers, reaching out to young and old, local and global.

Excerpts



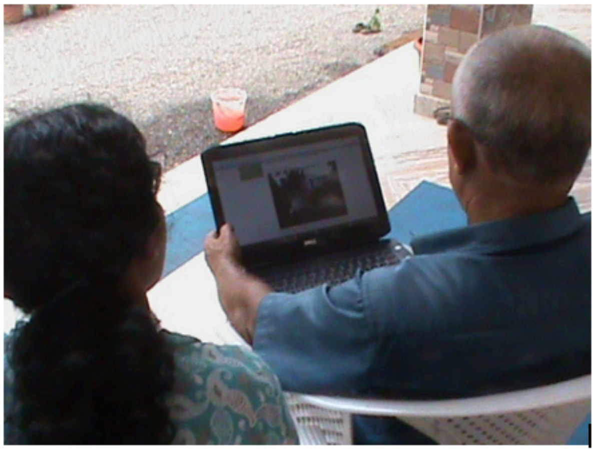
Signboard on the platform of one of the numerous trees that surround the temple, indicating the locality of the group to assemble at this site, (Picture: Own)

One of the groups assembled in 2014 (Picture: Own)

Validation

Once the presentation had reached a logical point, in 2016, I returned to the various persons I had obtained information from, for their validation and feedback. I also had independent knowledgeable individuals review the content, to ensure I had captured key terms in the narrative correctly.

The snapshots of the Bepur group viewing the site, are below. One of the youngsters of this group had asked me, when I was gathering my content – "What will be the result of your research? Will we get to see it, or will it sit in some library that we cannot access?"



Although such an in-person validation was possible for the pilot site, as the system scales to multiple locations and contributors, as is the eventual goal, quantifiable and less resource-intensive methods of validation, using computational tools and systems as appropriate, will need to be implemented.

Future work

1. **Multi-Lingual Captions**
   The photo-narrative approach needs to be explored further, to include multi-lingual capability, especially in the narrative captions that will further increase accessibility.
2. **Semantics**
   Working out the conceptual categories and a suitable meta-data taxonomy to describe the content, will be crucial to make Limories a 'living' site. The diagram below depicts the overall process flow currently envisaged for the system.
3. **Scaling out**
   In parallel, strategies to scale out to other sites also need to be worked out. A second site has been chosen. The prospect of using local volunteers is also being explored.
4. **Social media as a source?**
   As Limories scales out, it 'might', in due course, use appropriate and relevant social media

content. However, a primary consideration, if so, would be appropriateness of content. A key intent of Limories is to reach out to all audiences, including children, for the younger generation to know the localities around them, and the associated memories they hold, better. Content would need to be accordingly appropriate.

Worked out

Note: Chart to be read bottom-up

Working out the conceptual categories and meta-data, is the next major stage in the Limories journey, as the chart illustrates. This, and scaling out to other sites, with controlled crowd-sourcing, are crucial next steps for Limories, seminal to realizing its vision, to help answer: **What is it that makes a place unique and special, to all the people in whose memories the place resides?**

Introduction

A lot of Digital Humanities (DH) research involves applying Natural Language Processing (NLP) tasks, such as, sentiment analysis, named entity recognition, or topic modeling. A large amount of NLP software is already available. On the one hand, there are frameworks that bundle software for different tasks and languages (e.g., NLTK [Bird et al, 2009], or xtas1), and on the other hand there are tools that target specific tasks (e.g., gensim, Rehurek and Sojka, 2010). As long as researchers do not need to combine tools from different packages, it is usually relatively easy to write scripts that perform the task. However, for innovative research, combining tools often is required, especially when working with non-English text. This abstract presents work in progress on NLP Pipeline (**nlppln**), an open source tool that improves access to NLP software by facilitating combining NLP functionality from different software packages2.

nlppln is based on Common Workflow Language (CWL), a standard for describing data analysis workflows and tools

(Amstutz et al, 2016). The main advantage of using a standard is that any existing NLP tool can be integrated into a workflow, as long as it can be run as a command line tool. This flexibility is missing from existing frameworks for creating NLP pipelines, such as DKPro (Eckart de Castilho, and Gurevych, 2015) using the UIMA framework (Ferrucci, and Lally, 2004). In addition to improved reuse of existing software, CWL increases research reproducibility, as it provides a standardized, formal record of all steps taken in a processing pipeline. Finally, CWL workflows are modular. This means that individual processing steps can easily be swapped in and out.

To demonstrate how NLP tools can be combined using nlppln, we show what need to be done to create a pipeline that removes named entities from a directory of text files. This is a common NLP task, that can be used as part of a data anonymization procedure.

The Software

An NLP pipeline or workflow is a sequence of natural language processing steps. A 'step' represents a specific NLP task, that is executed by a single tool. Tools require input and produce output. The basic units in CWL are command line tools (i.e., tools that can be run from the command line). In order to be able to run a command line tool, CWL needs a specification. The **nlppln** software helps creating those specifications. In addition, **nlppln** provides functionality to convert existing NLP tools written in Python to command line tools. Finally, the software helps users to combine (existing and new) processing steps to pipelines.

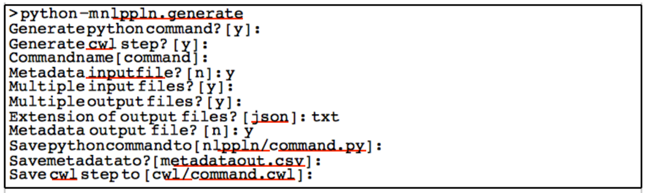
In the next section, we explain how **nlppln** facilitates creating NLP steps, and in "Constructing Pipelines" we demonstrate the creation of an NLP pipeline for data anonymization.

Generating Steps

nlppln allows users to generate CWL specifications for existing NLP tools. To simplify the generation of CWL specifications, we use a convention for NLP tasks. The convention assumes that there can be two types of input parameters: a list of files for which the command should be executed, and/or a file containing metadata about the texts in the corpus. Output parameters consist of a directory where output files are stored (usually there is one output file for every input file) and/or a file in which metadata is stored. So far, almost all steps that are currently available in **nlppln** follow this convention. Be that as it may, we would like to emphasize that it is possible to deviate from this convention; for example, when existing NLP functionality requires different parameters (e.g., the name of a directory containing the input files instead of a list of input files). This does however mean that the user has to adapt the CWL specification by hand.

In addition to CWL specifications, **nlppln** allows users to generate boilerplate Python command line tools. A boilerplate command line tool contains generic functionality, such as opening input files and saving output files, but lacks implementation of the specific NLP task. The generated Python command can be used to turn existing NLP functionality into command line tools, and to create Python command line tools for new NLP tasks.

Python commands and associated CWL steps are generated using a command line tool that requires the user to answer a sequence of yes/no questions. Listing 1 shows what that looks like for a (hypothetical) command 'command', that takes as input a metadata file and multiple input files, and produces as output multiple text files and metadata.



```
>python -m nlppln.generate
Generate python command? [y]:
Generate cwl step? [y]:
Commandname [command]:
Metadata inputfile? [n]: y
Multiple input files? [y]:
Multiple output files? [y]:
Extension of output files? [json]: txt
Metadata output file? [n]: y
Savepythoncommandto [nlppln/command.py]:
Savemetadatato? [metadataout.csv]:
Save cwl step to [cwl/command.cwl]:
```

Listing 1: Generating a CWL specification and associated boilerplate Python command using **nlppln.**

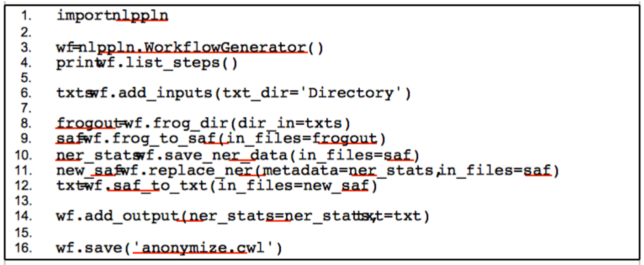
Constructing Pipelines

To combine text processing steps into a CWL pipeline, **nlppln** provides an interface that allows users to write a simple Python script. We demonstrate this functionality by creating a pipeline that replaces named entities in a collection of text documents. Named entities are objects in text referred to by proper names, such as persons, organizations, and locations. In the example pipeline, named entities will be replaced with their named entity type (i.e., PER (person), ORG (organization), LOC (location), or UNSP (unspecified)). The pipeline can be used as part of a data anonymization procedure.

The pipeline consists of the following steps:

1. Extract named entities from text documents using frog (van den Bosch et al, 2007), an existing parser/tagger for Dutch
2. Convert frog output to SAF, a generic representation for text data3
3. Aggregate data about named entities that occur in the text files
4. Replace named entities with their named entity type in the SAF documents
5. Convert SAF documents to text

All steps required for this pipeline are available through **nlppln**. Listing 2 shows the script that creates a CWL workflow for this pipeline. After importing **nlppln** (line 1), a new WorkflowGenerator object is created (line 3), and the available NLP steps are listed (line 4). Next, the script specifies the workflow inputs (line 6). In this case, there is a single input, which is a directory containing text files. This directory is the input of the first step, which is frog_dir (line 8). The output argument txts contains the internal CWL name of the input parameter (line 6). By assigning its value to the input argument dir_in of frog_dir (line 8), the output is connected to the input. Steps 1 to 5 from the pipeline description correspond to lines 8 to 12 in listing 2. After the remaining steps steps of the workflow are added (lines 9–12), the workflow outputs are specified (line 14). Finally, the workflow is saved to a CWL file (line 16).



```
1.   importnlppln
2.
3.   wf=nlppln.WorkflowGenerator()
4.   printwf.list_steps()
5.
6.   txts=wf.add_inputs(txt_dir='Directory')
7.
8.   frogout=wf.frog_dir(dir_in=txts)
9.   saf=wf.frog_to_saf(in_files=frogout)
10.  ner_stats=wf.save_ner_data(in_files=saf)
11.  new_saf=wf.replace_ner(metadata=ner_stats,in_files=saf)
12.  txt=wf.saf_to_txt(in_files=new_saf)
13.
14.  wf.add_output(ner_stats=ner_stats,txt=txt)
15.
16.  wf.save('anonymize.cwl')
```

Listing 2: Python script for constructing the pipeline to replace named entities in text files.

Conclusion

To help DH researchers to (re)use and combine existing NLP software, we presented **nlppln**, an open source Python package for creating flexible and reusable NLP pipelines in CWL. nlppln comes with ready-to-use NLP steps, facilitates creating new steps, and helps combining steps into standardized workflows that are portable across different software and hardware environments. Compared to existing frameworks for creating NLP pipelines, CWL and **nlppln** add flexibility and improved research reproducibility.

nlppln is a work in progress. An important challenge that needs to be addressed is the fact that there is no standard data format for representing text and/or information extracted from text. This means that we will have to add NLP steps that convert different data formats (cf. Eckart de Castilho, 2016)). For future work, we plan to implement additional NLP steps and pipelines, including functionality that targets more languages. We would also like to add visualizations of pipelines and allow users to run pipelines directly from **nlppln**.

Towards a Digital Narratology of Space

Universität Stuttgart, Germany

Introduction

Besides time, characters and plot, space is one of the main components in storytelling. But despite its importance as a category for the setting of narrative action and unlike the other mentioned categories, the conceptualisation of space has long been neglected in narratological research. This holds true even after the so-called *spatial turn* (Soja 1990) in cultural history, that lead to a renewed interest and to fruitful insights into space as a metaphorical concept. However, a systematic description of the means by which space is created in narratives is still in its beginnings (e.g. Dennerlein 2009, Piatti et. al. 2009).

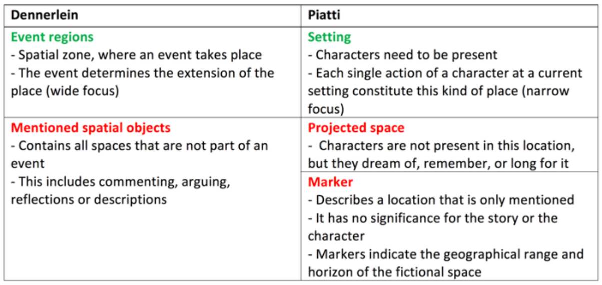
This is at least partly due to the fact that space poses substantial problems for modeling. The creation of space in narratives is often dynamic and based on implicit information: Rather than constructing a given, mathematical space beforehand, stories tend to evolve their setting in relation to its characters that constitute space through their actions. Spatial information in stories therefore highly depends on the characters that act, move or perceive within it. Especially in fiction, this also means that spatial information is often fuzzy and imprecise (Piatti et. al. 2009), since narrators quite frequently are more interested in telling a story than designing a detailed, coherent setting for it. Whereas these problems are hard to handle in traditional literary studies, they present serious yet interesting challenges for a digital formalization.

In our paper, we will illustrate the complex tasks that have to be tackled by a digital narratology of space based on an exemplary annotation workflow, that we will outline for the description of spatial elements in Jules Verne's *Around the world in Eighty Days.*

Challenges for a digital narratology of space

We describe the following major problems that can be grouped into a chain of work-tasks:

1. Basic information on the setting of a narrative can be retrieved by extracting the place names from a text (NER). However, an automatic extraction is flawed by well-known problems of disambiguation (cf. for example, Barbaresi / Biber 2016). Since space in narration is highly dependent on characters that are placed in it, these entities have to be detected as well.
2. Place names are not the only kind of spatial information that can be found in texts. Besides others, space is also constituted with the help of nouns that do not necessarily have an inherent spatial component (for example, a *car* in a text can be the subject of a description, but it turns into a space marker if someone enters it).
3. Spatial entities (names and nouns) can be referred to by co-reference.
4. Spatial entities in a text are not always the setting of narrative actions. Place names or nouns can also only be mentioned, dreamed of, remembered, reflected on etc. This different functionality has to be taken into account when it comes to the automatic generation of literary maps (eg. Moretti 1998, Piatti 2008). To capture this opposition, Dennerlein (2009) separates *event regions* from *mentioned spatial objects* in her conception. *Event regions* are defined as spatial zones, where events take place. In contrast, *mentioned spatial objects* contain all spaces that are not event-related. Piatti et. al. (2009) develop a similar model: Their concept of *setting* closely corresponds with *event regions*, whereas *projected space* and *marker* give a finer differentiation of the notion of *mentioned spatial objects* (cf. Figure 1).



Dennerlein	Piatti
Event regions - Spatial zone, where an event takes place - The event determines the extension of the place (wide focus)	Setting - Characters need to be present - Each single action of a character at a current setting constitute this kind of place (narrow focus)
Mentioned spatial objects - Contains all spaces that are not part of an event - This includes commenting, arguing, reflections or descriptions	Projected space - Characters are not present in this location, but they dream of, remember, or long for it
	Marker - Describes a location that is only mentioned - It has no significance for the story or the character - Markers indicate the geographical range and horizon of the fictional space

Figure 1: Comparison of spatial concepts from Katrin Dennerlein Barbara Piatti

Annotation Workflow

t_22	.	.	.					Movelink(ID=mvl1, trigger=m1, mover=se1, goal=p1)

The complexity of spatial information demands for a multi-faceted approach. Figure 2 shows a spreadsheet with the beginning of chapter 14 of Verne's *Around the World in Eighty Days* that has automatically, semi-automatically and manually been enriched with multiple layers of annotation.

First, the text was tokenized, lemmatized and POS-tagged (columns 1-4).

Second, Named Entity Recognition (NER) was applied to the text (columns 5, both steps were performed with Weblicht [2012]). The NER also identifies the names of the characters. The results of the NER have to be corrected manually. To improve the automation of this step the exploitation of other toponymical bases like Geonames and OpenStreetMap will be discussed.

Thirdly, to generate column 6, we used theme-specific wordlists that we built on the base of existing lexicological ontologies (*GermaNet* for German Texts [Hamp/Feldweg 1997, Henrich/Hinrichs 2010]. English Wordlists as shown were provisionally generated manually, but can be built in a similar way). These wordlists were used to automatically tag the text. In Fig. 1, 'valley' has been annotated as *LSC*, which means that it belongs to the word field *landscape*. So far, we created wordlists for *landscape* and *architecture* (in German), which cover a high amount of place nouns. The annotation can be manually supplemented and new wordlists can be created.

Fourthly, in column 7, 'the beautiful valley of the Ganges' was (manually) annotated as *event region* according to the model of Dennerlein (2009). An automatic differentiation between *event regions* and *mentioned spatial objects* will be a challenging task. However, we consider a rule-based extraction of dependency paths to approach the problem

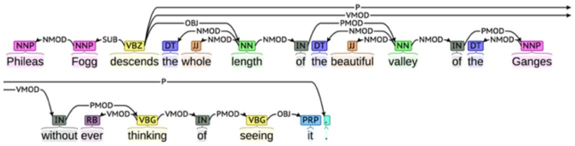

Figure 3 shows a parse tree of the sentence from Verne's text. The pattern [Character – SUBJ – Verb of Motion – OBJ – place noun] is likely to indicate an *event region*. By gaining several similar patterns with high precision regarding the identification of *event regions*, we assume to collect features for a future implementation of machine learning methods.

Fifthly, in column 8, coreferences were annotated manually. We will consider different kinds of co-references: Spatial entities can be referred to by nouns (e.g. 'Paris / 'city') or pronouns. Also, certain deictics ('here', 'there') might refer to spatial antecedents. However, a reliable automatic coreference resolution, which would be highly desirable for many kinds of narratological analysis, is out of the scope of this paper.

Finally, we included a column (9) for annotations that are based on the modified tag-set of the ISO-Space-standard (Pustejovsky et. al. 2011a und b), as they are presented in the SpaceEval Annotation Guidelines (2014).

Visualizations and Outlook

With the help of this semi-automatic and multi-layered method, we hope that we can make use of the strength of the different approaches and combine their advantages (it would be highly beneficial, for example, to combine Dennerlein's category with an ISO-space-annotated text to enhance their rule-based detection).

The potential of their combination shall be demonstrated by two examples of visualizations that draw on named entities and wordlists.

A network of spatial markers

As Piatti et. al. (2009) pointed out, the impreciseness and semantic potential of spatial information in literary texts sometimes demand visualizations other than geographical maps.

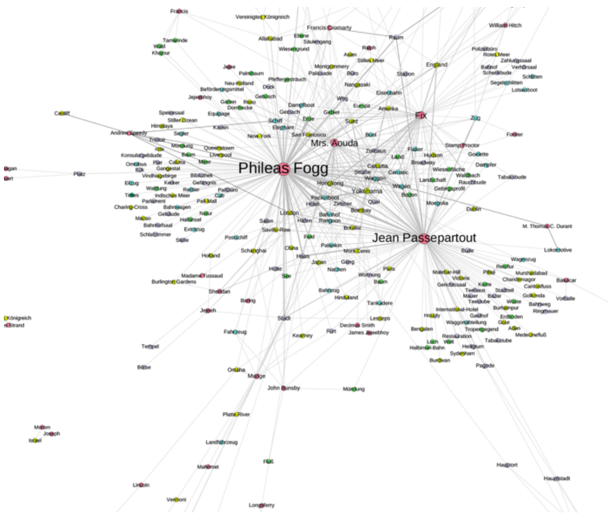

Figure 4 shows a co-occurrence network of characters and place markers in *Around the world in Eighty Days*: Characters appear in red, place names in yellow. Place nouns are divided into the sub-categories *landscape* (green), *architecture* (grey) and *transport* (blue). In a straightforward approach, we established edges whenever a character and a spatial marker appear in the same sentence. The nodes have been sized according to their degree (the number of their connections), which can be related to Juri Lotman's (Lotman 1977) concept of mobile vs. immobile characters: Characters which are connected to many places like Phileas Fogg and Passepartout are more likely to be main characters than characters with a lesser degree.

(The visualization was established with Gephi [Bastian et al. (2009)]).

Word-list-based Frequency Analyses

Figure 5 shows the distribution of *landscape* and *architecture* terms over the whole text of *Around the world in Eighty days* compared to a corpus of 451 German novels taken from the TextGrid-Repository (TextGrid Konsortium 2006-2014, licensed CC-BY-4.0), which cover a time range from 1700 to 1920.

Every text was chunked into 10 'segments' (x-axis), for which we calculated the relative percentage of the vocabulary from the corresponding word field ('value', y-axis). The graph shows a noticeable peak in the use of architectural vocabulary in the last third of the text, which can serve as a starting-point for a *close reading* of the text. However, to take full advantages of *distant reading* techniques for spatial analysis, more refined methods and annotated corpora are necessary. We hope that these methods can be developed by considering the challenges outlined in our basic model in this paper.

Evaluating Research Practices in the Digital Humanities by Means of User Activity Analysis

Niels-Oliver Walkowski
walkowski@bbaw.de
Berlin-Brandenburgische Akademie der Wissenschaften Germany

Approaches to the Evaluation of DH Research Processes

The documentation of digital research processes has been a heavily discussed topic for some years now. It is most often addressed by the term *provenance*. In most cases, provenance data is created to record the chain of production of digital research results, in order to increase transparency in research and make such results reproducible.

In more recent times, a slightly different version of this topic has appeared in the field of digital humanities. Accordingly, digital research processes are modeled and documented with the aim to identify methodologies and practices of digital research in the arts and humanities on a broader scale. Two models have been introduced in this respect. One is the *Scholarly Domain Model* (SDM) (Gradmann et al, 2015) the other is the *NeDiMAH Method Ontology* (NeMO) (Constantopoulos, Dallas, and Bernadou, 2016). Both models provide formal semantics for the description of research processes as well as for their methodological evaluation.

The project environment in which these models were defined was dominated by European infrastructure projects, specifically *DARIAH* in the case of NeMO and *Europeana* in the case of SDM. Accordingly, such models aim to identify user needs and the qualitative use of infrastructure services as a first priority. However, it is also easily possible to refer to them in a broader perspective of *laboratory research* and *science studies*. For the case of the digital humanities community such a perspective corresponds with this community's wish to develop a unique methodological self-awareness.

Upon closer observation, the two models take up a different approach to accomplish their goals. In terms of NeMo, applications of the model describe research processes after they have taken place. In contrast, SDM makes reference to the concept of "modeling for" by Clifford Geertz and describes research processes in advance.

Such difference calls for a more concise evaluation of the terminology that was used before. In the research literature three concepts are used to distinguish between three possible viewpoints from which research processes can be described (Hunter 2006). These concepts are: workflow, provenance and lineage. As it has been indicated in the evaluation of SDM and NeMO the difference of these viewpoints is marked by the place in time from which they look at a research process. As such, it is also possible to call these concepts "prescribing", "inscribing", and "describing".

In accordance with this systematization SDM defines workflows while NeMO presents lineages. What is missing however, is real provenance data that is created and modeled in order to systematically evaluate digital humanities practices. More specifically, this means data which is recorded during the research process. The main goal of this presentation is to introduce an approach for how such provenance data can be created and modeled meaningfully to reach its goal by way of example. The example is the Wissensspeicher at the Berlin-Brandenburg Academy of Sciences and Humanities. The Wissensspeicher connects all digital resources of the academy in a way that lets the user interact not just with metadata but with parts of the content itself. The work which will be presented is part of the evaluation phase of the DARIAH-DE project that started in March 2016.

When evaluating research practices provenance data has some advantages in comparison to workflow or lineage data. On the one hand, it is easier to obtain very detailed data. On the other hand, semantic implications which might predefine the results of the evaluation are less necessary. For instance, in the SDM primer the concept of annotating exists before it is applied to an activity in a specific situation. In consequence, research results about digital annotation practices are biased. They depend on personal decisions of someone who classifies activities as annotating, or on a normative concept of annotating. For the identification of new research practices in digital environments, both aspects are problematic. Provenance data does not have the same risk because it is mostly created before classification takes place. The only aspect which is predefined is the fact that recordable actions take place and that these actions form part of a broader research context.

Nevertheless, the implementation of technological solutions for the creation of provenance data in these circumstance is more complicated than in common situations where provenance data is created. It is not enough to record which software component modifies a digital resource at a certain point of time as it happens in e-science. The "resource" is the research process itself, the actions take place on multiple levels and such actions are carried out not only by software but also by humans.

User Activity Analysis and Digital Humanities Research Processes

In fact, there is one field of research which addresses a comparable situation and this field is **user activity analysis.** In user activity analysis, human-computer-interaction is recorded in order to evaluate the user with respect to a specific research interest. The approach is used in areas like **e-commerce** and **online social networks** research in order to create services like recommendation systems (Plumbaum, Stelter, and Korth 2009) or to analyze social behavior (Dang et al. 2016). There are few examples of user activity analysis in academic digital environments. Suire et al. (2016) use this approach in the cultural heritage domain while Vozniuk et al. (2016) applies it to model learning processes in e-learning environments.

Having said that, no ready-made solution exists which can be easily used in the present context. Instead different approaches to user-activity analysis have to be evaluated in order to decide which ones can be adopted. Nevertheless, under the circumstances of evaluating digital research practices these decisions remain contingent. Digital research takes place in very different digital environments and under different conditions. Thus, in every situation in which digital research practice should be evaluated a different selection from the existing set of options might be the best. An overview of these options will be published in a DARIAH-DE report in the future.

The advantage of the Wissensspeicher use-case is the fact that it is a web platform– most user activity analysis takes place on websites and in web environments. There are two major tasks which need to be distinguished. The first task is user activity tracking and concerns how the data is created. The second task is the actual analysis. It demands to evaluate in which sense the created data constitute meaningful events and how to make sense out of these events.

Use–Case: Wissensspeicher

The Wissensspeicher implements user activity tracking by combining three different strategies: http-request logging, browser-event parsing and user annotations. Http-requests are logged by virtue of the *Django* request object and the *logger* library in the Python Django app that creates the website. Thereby request information can be pre-processed when it is detected. When a page is loaded in the browser a *JavaScript* client registers event listeners for page elements and certain user actions. Each event that is triggered causes the client to parse relevant information in the *DOM* of the *HTML* including microdata which has been created in the Django app in advance. Additionally, the user is able to directly give feedback in some situations. The created data is stored in a *MongoDB* database.

User activity analysis is also realized by virtue of three steps. In a certain way these steps resemble the three angles of workflow, provenance and lineage. First, events are evaluated in a so called *task model*. This task model describes ideal sequences of actions and user goals as conceived by the project employees. Second, users are evaluated by applying the **thinking aloud** technique from the field of **usability testing.** Finally, existing data will be evaluated to identify common event sequences by computing its clusters. A systematization of the results from these evaluations will enables researchers to associate certain meanings with events in such a way that the data can be analyzed to permit insights into research practices within the use case.

A Dialogue of Approaches

This presentation will summarize activities to evaluate research practices and methods in the digital humanities. It will outline a unique and complementary approach and indicate how this approach can be used in conjunction with existing digital humanities research practices. Finally, the implementation and results will be described up to the point that such results are present after two-thirds of the project time has elapsed.

Collaborative Writing to Build Digital Humanities Praxis

Brandon Walsh
bmw9t@virginia.edu
University of Virginia, United States of America

Introduction

Emergent programs like those associated with the Praxis Network have redefined the possibilities for digital humanities training by offering models for project-based pedagogy. These efforts provide innovative institutional frameworks for building up and sharing digital skills, but they primarily focus on graduate education. The long-term commitments that they require can make them difficult to adapt for the professional development of other librarians, staff, and faculty collaborators. While members of these groups might share deep interests in undertaking such programs themselves, their institutional commitments often prevent them from committing the time to such professional development, particularly if the outcomes are not immediately legible for their own structures of reporting.

My talk argues that we can make such praxis programs viable for broader communities by expanding the range of their potential outcomes. This talk explores the potential for collaborative writing projects to develop individual skillsets and, by extension, the capacity of digital humanities programs. While the example here focuses on a coursebook written for an undergraduate audience, I believe the model and set of pedagogical issues can be extrapolated to other circumstances. By considering writing projects as potential opportunities for project-based development, I argue that we can produce professionally legible outcomes that both serve institutional priorities and prove useful beyond local contexts.

Case Study

The particular case study for this talk will be an open coursebook written for a course on digital text analysis (Walsh and Horowitz, 2016). In the fall of 2015, Professor Sarah Horowitz, a colleague in the history department at Washington and Lee University, approached the University Library with an interest in digital text analysis and a desire to incorporate these methods in her upcoming class. As the Mellon Digital Humanities Fellow working in the University Library, I was asked to support Professor Horowitz's requests because of my own background working with and teaching text analysis. Professor Horowitz and I conceived of writing the coursebook as a means by which the Library could meet her needs while also building the capacity of the University's digital humanities resources. Our model in this regard was as an initiative undertaken by the Digital Fellows at the CUNY Graduate Center, where their Graduate Fellows produce documentation and shared digital resources for the wider community. We aimed to expand upon their example, however, by making collaborative writing a centerpiece of our pedagogical experiment. Through her involvement in the the creation of the course materials, Professor Horowitz engaged with a variety of technologies: Markdown, Git, and GitHub. The process also required synthesis of both text analysis techniques and disciplinary material relevant to a course in nineteenth-century history. As a result of our initial collaboration in writing the materials and teaching the course, Professor Horowitz is prepared to offer the course herself in the future without the support of the library. In addition, we now possess course materials that could, after careful structuring and selection of platforms, be reusable in other courses at our own institution and beyond.

This type of writing collaboration can fit the professional needs of people in a variety of spaces in the university. Course preparation, for example, often takes place behind the scenes and away from the eyes of students and other scholars. With a little effort, the hidden labor of teaching can be transformed into openly available resources capable of being remixed into other contexts. As Shawn Graham (2016) has illustrated through his own resources for a class on Crafting Digital History, course materials can be effectively leveraged to serve a wider good in ways that still parse in a professional context. In our case, the collaboration produced public-facing web writing in the form of an open educational resource. The history department regarded the project as a success for its potential to bring new courses, skills, and students into the major as a result of Professor Horowitz's training. The University Library valued the collaboration for its production of open access materials, development of faculty skills, and exploration of workflows and platforms for faculty collaboration. We documented and managed the writing process in a GitHub repository. This versioned workflow was key to our conception of the project, as we hoped to structure the project in such a way that others could copy down and spin up their own versions of the course materials for their own needs. We were careful to compartmentalize the lessons according to their focus on theory, application, or course exercises, and we provided documentation to walk readers through the technical process of adapting the book to reflect their own disciplinary content.

Implications for DH Praxis

My talk argues that writing projects like this one provide spaces for shared learning experiences that position student and teacher as equals. By writing in public and asking students and faculty collaborators to discuss, produce, and revise open educational resources, we can break down distinctions between writer and audience, teacher and student, programmer and non-programmer. In this spirit, work by Robin DeRosa (2016) with the Open Anthology of Earlier American Literature and Cathy Davidson with HASTAC has shown that students can make productive contributions to digital humanities research at the same time that they learn themselves. These contributions offer a more intimate form of pedagogy – a more caring and inviting form of building that can draw newcomers into the field by way of non-hierarchical peer mentoring. It is no secret that academia contains "severe power imbalances" that adversely affect teaching and the lives of instructors, students, and peers (McGill, 2016). I see collaborative writing as helping to create shared spaces of exploration that work against such structures of power. They can help to generate what Bethany Nowviskie (2016) has recently advocated as a turn away from the Kantian ideal of an isolated, reasoning self and towards, instead, a "feminist ethics of care" to "illuminate the relationships of small components, one to another, within great systems." By writing together, teams engage in what Nowviskie (2011) calls the "perpetual peer review" of collaborative work. Through conversations about ethical collaboration and shared credit early in the process, we can privilege the voice of the learner as a valued contributor to a wider community of practitioners even before they might know the technical details of the tools or skills under discussion.

Collaborative writing projects can thus serve as training in digital humanities praxis: they can help introduce the skills, tools, and theories associated with the field, and projects like ours do so in public. Productive failure in this space has long been a hallmark of work in the digital humanities, so much so that "Failure" was listed as a keyword in the new anthology *Digital Pedagogy in the Humanities* (Croxall and Wernick, 2016). Writing in public carries many of the same rewards – and risks. While a certain comfort with frustration can help one learn digital methods (Ramsay, 2016) not everyone is comfortable with what Stephen Ramsay (2014) describes as a "hermeneutics of screwing around." Many of those new to digital work, in particular, rightfully fear putting their work online before it is published. I argue that the clearest way in which we can invite people into the rewards of public digital work is by sharing the burdens and risks of such work. In her recent work on generous thinking, Kathleen Fitzpatrick (2016) advocates "rooting the humanities in generosity, and in particular in the practices of thinking *with* rather than reflexively *against* both the people and the materials with which we work". By framing digital humanities praxis first and foremost as an activity whose successes and failures are shared, we can lower the stakes for newcomers. Centering this approach to digital humanities pedagogy in the practice of writing productively displaces the very digital tools and methodologies that it is meant to teach. Even if the ultimate goal is to develop a firm grounding in a particular digital topic, focusing on the writing invites students and collaborators into a space where anyone can contribute. By privileging soft rather than technical skills as the means of engagement and ultimate outcome, we can shape a more inviting and generous introduction to digital humanities praxis.

The UNESCO Declaration on Cultural Diversity (United Nations, 2002) states the importance of Cultural Diversity as one of the "common heritage of humanity" and makes its defence "an ethical imperative indissociable from respect for the dignity of the individual." In declaring the hope, "that one day the declaration will acquire the same force as the Universal Declaration of Human rights", Koïchiro Matsuura, Director General, manifests the importance of the Declaration for global peace and one of the founding texts of the new ethics of the twenty-first century UNESCO (Wandl-Vogt et al, 2016).

There is a fundamental linkage between biological, linguistic and cultural diversity. "Over the past decade, the field of biocultural diversity has arisen as an area of transdisciplinary research concerned with investigating the links between the world´s linguistic, cultural, and biological diversity as manifestations of the diversity of life" (Maffi, 2005).

The interest goes back to the observation that all dimensions are under threat by some of the same forces. It was realized, that this may lead to dramatic consequences for humanity and the earth. "While it is widely acknowledged, that the degradation of the natural environment, in particular habitats, entails a loss of cultural and linguistic diversity, new studies suggest that language loss, in its turn, has a negative impact on biodiversity conversation. There is a fundamental linkage between language and traditional knowledge related to biodiversity. Local and indigenous communities have elaborated complex classification systems for the natural world, reflecting a deep understanding of their local environment. This environmental knowledge is embedded in indigenous names, oral traditions and taxonomies, and can be lost when a community shifts to another language" (UNESCO, n.d.). Several studies, mainly carried out on indigenous languages, demonstrate mutual benefits. UNESCO (see above) considers the safeguarding of traditional knowledge and indigenous as well as local languages used to transmit such knowledge as a yet "underused but promising tool for the conversation and sustainable management of biodiversity".

This paper introduces into a multidisciplinary, collaborative knowledge discovery environment (AAS and ACDH, 2016), established at the Austrian Academy of Sciences (AAS), Austrian Centre for Digital Humanities (ACDH) in close collaboration with Natural History Museum Vienna (NHM), launched on September, 1st, 2016.

The project aims to establish a collaborative open science workflow and enable knowledge discovery as well as experimental scholarship related to biodiversity, linguistic diversity and it´s cultural dimensions. It aims to serve as a social and technical infrastructure enabling research for a multidisciplinary community of practice. The portal contributes to the sustainable documentation and visibility of cultural diversity and traditional knowledge and to open it for the public.

In this paper we introduce into first results of our endeavor, yet focus on the design process and community building efforts concerning the "Biodiversity and Linguistic diversity portal" (diversity4bio).

diversity4bio started as a case-study-collaboration between Natural History Museum Vienna (NHM), Heimo Rainer, and Austrian Academy of Sciences (AAS), Eveline Wandl-Vogt, in 2012, in the framework of the European funded project "OpenUp! Opening up European Natural History Heritage for Europeana".

Based on the background of the partners (Taxonomy, Nonstandard-language Lexicography) and the OpenUp!-projects main focus (common names for Europeana metadata) the first step to get towards results was to work on linguistic diversity.

The partners designed the project as a community organization. Community organization in this paper is understood as organizing within communities defined by shared experience, shared curiosity and interests as well as shared (virtual) work space. Community organization is a process by which a community identifies needs and takes action, and in doing so develops co-operative attitudes and practices (Ross, 1955)

The main characteristics of Community organization are discussed on the given example (Wallin, 2016):

1. **The boundaries are fluid, informal:** Everybody who contributes to diversity4bio belongs to the network. There is no need of a certain scientific status or collaboration contract. Members support each other to find the right place to fit in. Still, it is visibility, citation and reliability is relevant for the network, which means a high degree on transparence for data interaction and publication.
2. **Significant incorporation of voluntary labor:** Community organization does not end in legal contracts or financial remuneration. diversity4bio recently is a loose network, where "members" are connected by common spirit and visions for further developments rather than legal contracts.
3. **Significant open sharing of knowledge:** diversity4bio is aiming to bring together experts to exchange and explore. The authors implement open science workflows based on the actors needs and the visons of the open science definition. It is introducing open science commons especially in research areas where these are still atypical, e.g. in traditional lexicography units. The digital transformation is described as a time taking process of building trust, where first sample data sets – e.g. names for living organisms – are implemented into new collaborative, open approaches, enriched and methodologically innovatively exploited.
4. **Collaborative communities display:** Behind the virtual portal scenery, there is a shared ethic of independent contribution and there is a formalized set of norms of interdependent process management as well as an interactive social character and identity. Community building was a process of several years, which is reflected in the presentation, e.g. face to face meetings of the protagonists, just after first results of collaboration (biological data + linguistic data > Europeana-metadata workflow) workshop to connect others and opening up of the group towards a portal and first publication of results.

The very interactive and flexible community organization model is certainly a challenge, especially as diversity4bio is mixing up several disciplines without a very certain or concrete research focus.

Based on this fact we do have established network facilitators for botanics/taxonomy, Heimo Rainer, and cultural data/lexicography, Eveline Wandl-Vogt.

Technically seen, diversity4bio is a first example for an open science workflow design. The architecture makes use of existing (freely available) technologies and connects with existing infrastructures.
The architecture consists of three layers:

1. The Human Interface Layer
2. The Persistent Layer
3. The Enrichment Layer

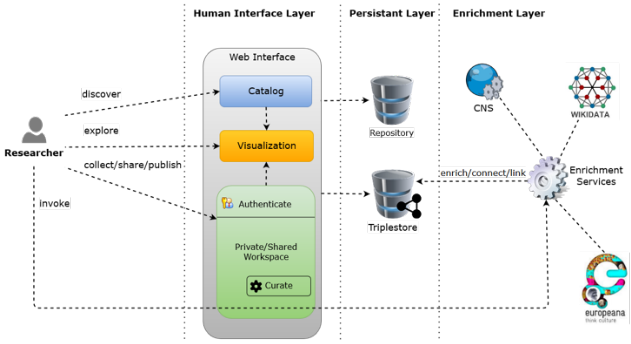

Figure 1: Pilot-architecture of the open workflow for the diversity4bio © Davor Ostojic

Data Visualization is part of the Human Interface Layer and developed within the project exploreAT! (exploring austria´s culture through the language glass). Furthermore, within the COST action IS1305 ENeL (European Network of electronic Lexicography) the interlinking and the use of the framework was stimulated. This may be seen as example on how ongoing initiatives contribute to the collaborative approach and vice versa.

The portal offers a reconcile service. It queries the so called Common Names Service (CNS) at NHM for common names of living organisms in different languages for a given scientific name (Latin, Greek). The portal offers the opportunity of a CSV-import with the own data collection. Data import is time consuming. CNS itself is a distributed service.

Finally, the portal offers – as a first step – for a CSV-import of scientific names script-based RDF-modeling. Further enrichment services are in development, but at the time being not implemented into the portal, e.g. script-based semi-automatically interconnection with the Europeana – workflow mentioned above. Furthermore, out of the box repositories for researchers and citizens with less technical knowledge are necessary to keep in track with our vision to document traditional knowledge and related local language in development.

Finally, design probes for the collaborative process have been developed. The interlinked scientifically interpreted data may be reused to build a Pan-European (COST ENeL vision) or even global dictionary of plant names and envision based on this new movements for collaboration as well as research.

Using Big Data to Ask Big Questions

Leah Weinryb Grohsgal
lgrohsgal@neh.gov
National Endowment for the Humanities
United States of America

How can you use open data to explore history?

Historic American newspapers illuminate the rich history and texture of life. They contain stories about politics, sports, music, shopping, food, health, science, movies, and everything in between. From the affairs of everyday life to major international events, newspapers enable humanists to delve into the past, providing vantage points in big cities and small towns, east and west, north and south, from various political, religious, and cultural standpoints, and multiple language and ethnic communities.

But what happens when cultural institutions make a large-scale set of historic newspaper data available? How are digital humanists able to use aggregated data from thousands of American news publications to tell stories and provide analysis, from the quotidian to the momentous? To find out, the U.S. National Endowment for the Humanities (NEH) asked the public "how can you use open data to explore history?" in the Chronicling America Historic American Newspapers Data Challenge. This paper describes the challenge and its results, which serve as powerful reminders of the possibilities for matching open data collections with the tools and questions of the digital humanities.

The nationwide competition, led by the NEH Division of Preservation & Access, interrogated the possibilities for using the data in *Chronicling America*, a digital repository of historic United States newspapers. *Chronicling America* is an open access, searchable database of historic U.S. newspapers, with a newly expanded date range from 1690 to 1963 (the date range at the time of the challenge was 1836 to 1922). The database and web site are produced by the National Digital Newspaper Program, a long-term partnership between the NEH and the Library of Congress (LC). *Chronicling America* includes millions of pages of digitized newspapers—nearly 12 million at the time of this writing, with more being added all the time—and descriptive information contributed by states and territories across the country. The LC supports the long-term management of the collection, including providing open access to the data through a well-documented API to enable exploration of the collection in a variety of ways beyond the site's web interface.

To spur use of the API and collection, the Chronicling America Historic American Newspapers Data Challenge encouraged researchers to create digital humanities projects, big or small, using the newspaper data. The results demonstrate exciting possibilities for connecting the creators of digital collections and the humanities research communities using them. The contest urged entrants to use the data to show trends, insights, themes, or stories from history using newspaper data. The challenge's parameters were broad, encouraging entrants to be creative in thinking about the humanities questions they find most compelling, and how they might approach them using open humanities data from newspapers.

The NEH awarded six prizes for the Chronicling America Historic American Newspapers Data Challenge in 2016. Far from being theoretical or speculative, the contest and the winning projects highlight the practical ways in which this data can be used to explore a variety of humanities themes. In brief, the winning projects were:

America's Public Bible: Bible Quotations in U.S. Newspapers, by Lincoln Mullen. The site tracks Biblical quotations in American newspapers to show how the Bible was used for cultural, social, religious, and political purposes, and how it was a contested yet common text.

American Lynching: Uncovering a Cultural Narrative, by Andrew Bales. This site explores America's long, dark history of lynching and the role of newspapers as both catalysts for killings and platforms for reform.

Historical Agricultural News, by Amy Giroux, Marcy Galbreath, and Nathan Giroux. The site is a tool for exploring information on farming organizations, technologies, and practices, as a window into social, economic, and political history.

Chronicling Hoosier, by Kristi Palmer, Caitlin Pollock, and Ted Polley. This site tracks the origins of the word "Hoosier," its geographic distribution, and its positive and negative connotations over time.

USNewsMap.com, by Claudio Saunt and Trevor Goodyear. This site allows users to discover patterns, explore regions, and investigate how words, terms, and news spread.

Digital APUSH, by Ray Palin and the A.P. U.S. History Students at Sunapee High School. This class used word frequency analysis to discover patterns in news coverage of several major issues such as secession, the KKK, and Plessy v. Ferguson.

This paper illustrates the potential impact of humanities collections such as *Chronicling America* when their data are made freely and easily available. It describes the data available in this huge data repository, the mechanisms researchers and students can use to access it, and some of the challenges inherent in its large span. The paper addresses some of the technical specifications and program guidelines for the National Digital Newspaper Program, in which metadata standards for both access and preservation were primary concerns for the NEH and the Library of Congress in creating and maintaining the program. It also explains how the program's decade-old community has cultivated shared practices and specifications that contribute both to the longevity of this dataset and to other newspaper digitization efforts across the country.

Then, the paper gives information about the winning entries in the first Chronicling America Historic American Newspapers Data Challenge in 2016, which touched on a variety of important humanities themes like religion, race, literature, violence, agriculture, law, and geography. It explains how winners used cutting-edge technology to produce maps, visualizations, tools, and data mashups. Winners reported their initial questions, the importance of this data in answering them, their methods, and their future plans for the projects they built. This paper highlights their processes and the variety of results they produced.

Finally, the paper discusses broader lessons for humanities users of "big data" in *Chronicling America*. It shows the value of a contest in publicizing data in the humanities and its uses. It showcases different modes of collaboration among humanities researchers, libraries, information technology professionals, and other partners in the research endeavor. The paper also explores some of the challenges for humanities scholars working with large datasets, including representation, bias, categorization, and documentation. The intellectual work of the digital humanities projects described here involves the same problem identifying and research that humanists have always pursued, but the methods and investigation present new questions and opportunities. The paper suggests ways of maximizing the benefits of large datasets such as *Chronicling America* to the humanities.

Towards a New Approach in the Study of Ancient Greek Music: The Virtual Reconstruction of an Aulos “Early Type” from Sicily

Angela Bellia
angela.bellia@unibo.it
University of Bologna, Italy

The ancient site of Selinunte (Sicily) is recognised today as one of the most important archaeological sites of the Greek period in Italy. From its foundation as a colony around the second half of the VII c. through to the middle of the III c. BCE, Selinunte enjoyed a prosperous existence as reflected in its notable sanctuaries, and temples. In 2006, the Institute of Fine Arts at New York University began a research project on the acropolis under the direction of Prof. C. Marconi and in collaboration with the Archaeological Park of Selinunte. The project consists of a new, systematic and interdisciplinary study of the archaeology and architecture of the main urban sanctuary, beginning with its southern sector. In the years between 2006 and 2012, the survey also consisted of the investigation of the ‘South Building’. This structure is notable for its prominent position within the sacred space. From the time of its discovery (1876), its scale has attracted scholarly attention, and the ‘South Building’ has played a significant role in discussions about the spatial articulation and cults of the main urban sanctuary. The investigation included a systematic programme of documenting the buildings in the area and its digital reconstruction.

Several elements suggest the identification of the ‘South Building’ as an impressive theatral viewing area with particular acoustic qualities (Marconi and Scahill, 2015). This building belong to a group of theatral structures found in various regions of the Greek world. Many of these structures were not proper “theatres”, but rather primitive rows of seats (meaning non-canonical theatres, with linear and non-circular *theatra* and/or *orchestra*): they existed as “a place from where one could watch”, which is in fact the original meaning of the word *theatron*.

The quality of the stones was carefully selected in relation to their placement in the cultic theatres, based on structural, aesthetic, and, acoustic considerations. The acoustics of the linear *theatra* in the Greek world have never been analysed (Blesser and Salter, 2011): no study has focused on the acoustics of these theatres in order to understand how and why these spaces were chosen for performance. It is a category of buildings brought to the attention of scholarship by Anti (1947), but first investigated in relation to religious contexts by Nielsen (2002) in her study on cultic theatres in the ancient world; by Marconi (2013) in his study on the theatral structure of Selinunte; and by Hollinshead (2015) in her study on the steps as components of monumental construction at Greek sites as early as the VI c. BCE.

At Selinunte, the cultic theatre was built to accommodate spectators of performances associated primarily with Temple R, probably a temple of Demeter. One of the main striking finds among the votive depositions was the discovery of two parts of a bone *aulos*, which can be dated to 570 BCE (Marconi, 2014). This discovery is very significant, particularly with regard to the performance associated with the activity of Temple R (Marconi, 2013). The discovery shows the importance of music in this context which already existed in the Early Archaic period, that is, since its foundation.

In 2013, the Marie Curie Actions programme (IOF) funded the TELESTES project (622974): the main aim of this project was the reconstruction of musical development at Selinunte on the basis of material culture and written sources. It also included the study of the *aulos* from Temple R using a CT scan, an improved method for the visualisation and analysis of the instruments (Bellia, 2015). However, this survey still lacked an appropriate connection between the acoustics of the cultic theatre and musical activity related to the building. Thanks to the present project, auralisation techniques are used to explore the spatial dimension of sound in this cultic theatre, establishing a relationship between the spatial configuration of this structure and how this complements music. These data will help us to understand the aural perception of ancient peoples and the type of sound experiences they were exposed to.

This research is the first study on the virtual reconstruction of the acoustics of cultic theatres of the Greek world. Despite their relevance to the field of ancient music, no study has focused on the acoustics of these theatres in order to understand how and why these spaces were chosen for performance. Within this context, archaeoacoustics is being used as a new method for the analysis of historical heritage, enabling the evaluation of the sound quality of a space (Scarre and Graeme, 2006) by using auralisation techniques which allow cognitive and physical elements to be reproduced and combined (Eneix, 2014).

This project offers an innovative research method in the study of ancient Greek music, not only in its contextualisation of archaeological evidence, but also by making connections between digital and acoustic techniques. It is also hoped that the results will provide some foundations from which to create interpretative reconstructions of what the cultic theatres might have sounded like, using digital and acoustic technology. Moreover, this study will contribute towards overcoming the traditional methods in measuring ancient instruments, opening up a new disciplinary framework for the *interaction between 3D reconstruction of instruments, their respective sounds*, and the spaces of musical performances.

In order to analyse the acoustic characteristics of the cultic theatre of Selinunte, an acoustic survey will be carried out using an impulsive sound source located in two positions on the steps, and in the "orchestra". Measurements will be recorded using an impulsive sound source. This process will make it possible to obtain a virtual acoustic reconstruction of this space, including the incorporation of acoustic characteristics as another important aspect of its intangible heritage. The software used will be CATT-Acoustic, v. 9.0 c.

The digitisation process of the *aulos* is divided into two main tasks, namely the 3D scanning phase and the post-processing phase. The tools we plan to develop are divided into those involving the use of computational methods for processing the 3D models, and those involving the development of interactive tools aimed at engaging in the exploration of the instruments. The software used will be GEOMAGIC DESIGN X, with AVIZO, v. 9.0. Following the digital model will translated into artificial copies, using polymer as a material. We aim to obtain and to assess the auralisation of the acoustical properties of these 3D models.

In addition, the work will address the study of written sources as well as visual and archaeological documentation related to music performed in the cultic theatres of the ancient Greek world from the Archaic through to the Classical periods. The study will be conducted in order to understand the reasons that led ancient cultures to create these spaces, as well as reconstruct how they experienced them.

Expected results

Firstly, this research will provide the first acoustic model for the study of acoustical properties of cultic theatres in the ancient Greek world. The study will assess and recover the acoustics of the Selinunte theatre.

Secondly, the research will develop specific tools suitable for processing the resulting 3D models. It is also hoped that the results will provide some foundations from which to create experimental interpretative 3D reconstructions integrating acoustic models. The results will establish a new framework, which future researchers can use to advance their knowledge of the application of 3D technology for the documentation of instruments.

Finally, this project will offer an innovative research method in the study of ancient Greek music. This research aims to create a field of comparative studies of archaeomusicological research.

In conclusion, this research will develop a new theoretical basis, which will contribute to the establishment of a methodology at the crossroads of archaeomusicology, architecture, and acoustics and digital technologies. In addition, this study is part of a programme intended to valorise ancient cultural and musical heritage in the Mediterranean with cross-disciplinary approaches to human culture and technology, in order to unveil new meanings and create new research fields within the digital humanities and heritage science.

Optical Character Recognition with a Neural Network Model for Printed Coptic Texts

Introduction

Optical character recognition (OCR) is the process of extracting text from images. The final results are machine readable versions of the original images. Nowadays every modern scanner comes with some kind of OCR, but the results may not be satisfying when the OCR is applied to historical texts, that

1. do not use standard fonts,
2. are not printed by a machine,
3. have varying paper and font quality.

Furthermore, historical texts are not passed down through the centuries in their entirety but rather contain lacunae and fragmentary words. This makes automatic post-correction more difficult on historical texts than on modern ones.

We used two tools to create language- and even document- specific recognition patterns (or so-called models) to recognize printed Coptic texts. Coptic is the last stage of the pre-Arabic, indigenous Egyptian language. It was used to create a rich and unique body of literature: monastic, "Gnostic," Manichaean, magical and medical texts, hagiographies, and biblical and patristic translations. We found that Coptic texts have properties which make them excellent candidates for reading by computers. The characters can easily be distinguished due to their limited number and the fact that almost all the hand-written texts exhibit characters with highly consistent forms.

Related Work

The process of digitizing historical documents can be split up into at least three major steps: (1) pre-processing, (2) text prediction (OCR), and (3) post-processing or correction.

Although many works already tackled subproblems (He et al, 2005; Gupta et al, 2007; Kluzner et al, 2009), Springman et al.(2014) presented the first complete approach containing all major steps for historical Greek and Latin books.

The first OCR results for printed Coptic texts were achieved by Mekhaiel (see Moheb's Coptic Pages) by using Tesseract to create a model for Coptic texts. Tesseract assumes that the image was printed with a standardized font. Although it can be trained to use many different fonts, creating a general model that would satisfy scholars is not feasible. In the end, this model is sufficient for pure printed Coptic texts, but creates a lot of noise for texts with mixed languages or annotations. Such drawbacks can be easily overcome by checking against a dictionary, but historical languages often do not have a dictionary that could be considered complete, and the texts might only be fragments that require further analysis.

The recognition itself is performed by either Ocropy (Breuel, 2008) or Tesseract. Potentially, all character-based texts can be recognized. However, even though Mekhaiel provided a Coptic model for Tesseract, we were never able to achieve satisfying results on images which were not pre-processed.

Data Used

For training and testing, an expert on Coptic created a clean version and transcription of Kuhn's 1956 edition "Letters and sermons of Besa." This will also be made available to the interested public.

Besa is a fifth-century abbot of a monastery in Upper Egypt and Coptic writer, whose literary legacy consists mainly of letters to monks and nuns on questions of monastic life and discipline.

Simplified pages were created to find the limits of the trained models with optimal input data. Since creating simplified pages consumes a lot of time, we consider this task as impractical for real use scenarios. Nevertheless, the results on these simplified pages show the best possible prediction.

In Fig. 1 all characters and symbols that are going to be removed are marked red. The resulting simplified image can be seen in Fig. 2. By procedure, adjacent characters that are supposed to form one word are cut apart by gaps. Those gaps are going to be predicted differently by the two OCR engines.

Fig. 2, Simplified version (excerpt)

Methodology

There are two methods to train for Coptic texts:

(i) Tesseract needs a font as the baseline and matches the found letters against this font. This can be highly convenient since fonts do not show many variations within a single document. Additional fonts can be incorporated into the model with the drawback that the prediction requires more computational time. So far, we have used Mekhaiel's original model, and we are currently experimenting by adding document-specific characters to increase the accuracy of a single document.

(ii) Ocropy, on the other hand, does not require a font. For training, it requires only a partial transcription: the ground truth. This transcription is used to train a neural network that can recognize the characters. Ocropy's drawback is that the ground truth cannot just be the alphabet but requires multiple pages of transcribed text with a representative letter frequency. Ocropy's training process is measured in iterations. Springmann proposed working with at least 30,000 iterations (a comment made by Springmann in a private conversation, based upon his own experience).

For this contribution, we created an Ocropy model with a training set containing approximately 5,000 characters. This set includes superlinear strokes, braces and foreign characters which are not part of the Coptic alphabet.
Multilingual documents and documents containing foreign characters are considered complex. Stains on the document, bad image quality, and annotations like line numbers increase the complexity of documents as well. We, therefore, created special pages with reduced complexity. Our original pages were stripped offline numbering and footnote annotations. In the "clean" version, all foreign characters, punctuations and annotations inside the text were removed, leaving us with a pure Coptic text. We further stripped all clean versions of superlinear strokes, giving us the simplified version.

For testing, the selected pages were transcribed with corresponding 'original', 'clean' and 'clean without stroke or simplified' ground truths. All results were compared with 'Ocreval' (Baumann 2014)[9] against the ground truth.

Results

Prediction

Mekhaiel's original Tesseract model produced the best results on simplified pages with an accuracy of ~95%, while our Ocropy model performed better on the more complex pages. On the other hand, the Tesseract tends to produce predictable errors. Character ϣ will, for example, always be recognised as □; while, Ocropy produces unpredictable errors. Although our Ocropy model is less accurate on simplified pages, it surpasses Tesseract on noisier pages.

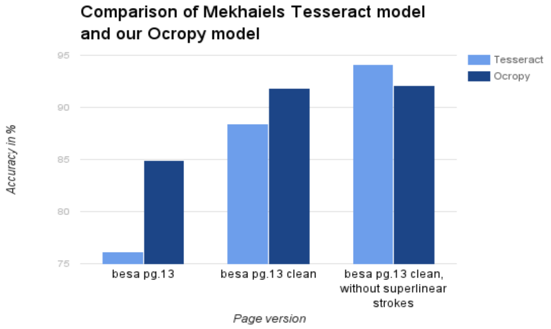

Fig. 3, OCR accuracy on different complexity levels

Costs

We measured that a skilled person needs roughly 10 minutes for manual transcription and 5 additional minutes for proofreading per page. Ocropy's models are built on top of transcribed images. Therefore, an initial ground truth is always required. Training with Ocropy does not require further human interaction but consumes up to two days of CPU power (Core i3/5 2.4GHz/3.2GHz, 8GB RAM, SSD), training cannot be run in parallel. Tesseract's training process, on the other hand, depends on the font extraction. We do not have enough data to estimate the time required to extract a font from an image. Both predictions still have to be checked manually, which can take up to 5 minutes. With clean pages and reduced proofreading time per page, Fig. 4 shows an optimal OCR workload reduction (red lines) in comparison to manual transcription (yellow line). A more realistic scenario is mentioned in the discussion.

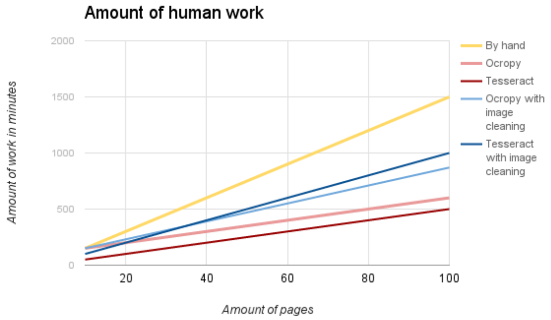

Fig. 4, workload comparison

Discussion

Our result shows that Tesseract outperforms Ocropy on simplified pages in terms of accuracy and amount of human work. Unfortunately, in a realistic scenario, the pictures will always contain some of the previously described complexities. Pre-processing of the data is, therefore, essential to obtain good results. In Figure 4, we also computed a more realistic scenario (blue lines) with a higher workload on pre-processing for Tesseract. It shows that creating an Ocropy model pays off for larger and more complex document sets.

Tesseract's overall acceptable performance is based on the fact that no model has to be trained. As creating and testing a model can consume more time than manual transcription and proofreading, the creation of clean images might still be less efficient than the manual approach even if a model can be reused.

As long as cleaned images images are one of the desired results, our works shows that the workload can be reduced by half. This applies especially to Ocropy, since ground truth creation and training fit into the normal transcription workflow.

Unicode ambiguities, which unfortunately result in encoding differences, require normalization and filtering. Otherwise, these encoding differences, which would not be seen as errors by humans, will be counted. Due to the same ambiguities, it is easy to mix characters from different code pages, especially on multilingual texts and text markings. It is, therefore, recommended that one use only corresponding code pages, especially with multilingual models. Tests with models containing multilingual fonts will be considered in further studies.

Conclusion

OCR of historical documents continues to be a hard problem, but we showed that utilizing OCR for the transcription of Coptic texts can reduce the overall workload. Since even the simplest images could not be recognized with 100% accuracy, further gains can only be achieved by better pre- and post-processing techniques.

A bigger workload reduction can be achieved by model reuse. However, no Coptic OCR models have been published besides Mekhaiel's. Therefore, we highly recommend publishing models alongside the transcription and suggest that it is possible to predict almost all well-preserved texts.

Also, although our model was able to partially predict multilingual texts, further studies are required. Multilingual texts require a specialized training process to compensate for the small numbers of foreign words.

Distinguishing Newspaper Genres. Exploring Automated Classification of Journalism's Modes of Expression

Frank Harbers
f.harbers@rug.nl
University of Groningen, the Netherlands

Juliette Lonij
juliette.lonij@kb.nl
National Library of the Netherlands, the Netherlands

Introduction

This paper examines the opportunities, approaches and issues of automatically classifying historical newspaper articles from the Netherlands for 'genre' as an expression of the historically and culturally determined conception of journalism. Genre is defined as "language use in a conventionalized communicative setting in order to give expression to a specific set of communicative goals of a disciplinary or social institution, which give rise to stable structural forms" (Handford 2010). As Barnhurst and Nerone (2001) argue: "The form includes the way the medium imagines itself to be and to act. In its physical arrangement, structure, and format, a newspaper reiterates an ideal for itself." Examining the generic form of newspaper articles form a historical perspective therefore sheds an interesting light on the way newspaper journalism has developed.

The digital era, which is typified as the 'age of abundance' of historical newspaper material, poses new challenges to historical research. Historical approaches to selecting and analyzing newspapers, rooted in the assumption of a scarcity of available material, had to be replaced with social scientific methods, such as quantitative content analysis (Nicholson 2013; Broersma 2009). Yet, manual quantitative content analyses are still highly time consuming and therefore expensive. Moreover, even then the size of the material that can be covered represents only a small part of the amount of material available (Harbers 2014). Automated forms of (content) analysis have the potential to alleviate or even solve this issue. As such, automatic forms of content analysis would be highly suitable for longitudinal and also comparative historical research into the development of newspapers, which particularly grapples with the overabundance of available research material (Broersma 2009).

However, although these approaches have a great appeal to researchers (Allen, Waldstein & Zhu 2008; Grimmer & Stewart 2013), research in this vein is mostly done in information science and linguistics. It seldom has a press historical perspective (Broersma 2009). Moreover, the emphasis has mostly been on topical modeling (Lee & Myaeng 2002), whereas attention for automatic classification of style and genre is scarce. Rather than determining what subjects and themes are being discussed, this project aims to examine genre as a modes of expression of newspapers, shedding light on the discursive context (Handford 2010). This is a particularly difficult task as genres are dynamic and can change or fade away over time while new ones can emerge. Moreover, genres are ideal-typical discursive constructs, which means the textual manifestations do not always match the characteristics of these constructs perfectly, nor can they always be clearly delineated from other genres.

The research question therefore is:

To what extent and how can historical newspaper articles be automatically classified for genre?

To examine this question, we have designed a research project that builds on an existing set of metadata describing several textual characteristics, such as genre, of a large sample of historical newspaper articles. This dataset was the result of a large-scale research project into the historical development of European newspapers with the title 'Reporting at the boundaries of the public sphere. Form, Style and Strategy of European Journalism, 1880-2005'. The set of metadata is derived from a manual content analysis that coded for genre based on a detailed rule-based coding manual. The metadata set relates to a corpus of approximately 33.000 Dutch newspaper articles from three types of Dutch newspapers, divided over the sample years 1885, 1905, 1925, 1965, 1985 and 2005 (Harbers, 2014). This set of metadata thus provides us with a number of labeled example articles that can be used to train and formally evaluate a classifier that is able to automatically predict the genre of additional samples of historical newspaper articles. In order to so the metadata **first** has to be connected to the full text of the corresponding digitized articles in the Dutch newspaper repository of the National Library (KB). The **second** step is to use this enriched dataset to train a classifier that can classify historical newspaper articles automatically.

This paper first shows a way to connect the metadata to the digitized historical newspaper articles (**Phase 1**). Ultimately, it offers an outline of a concrete machine learning approach, applying linear and non-linear classifiers, to predict the genre of a newspaper article. As a part of this, the paper discusses the different tools we have tried out and the problems we have encountered in the process (**Phase 2**). Specifically, the paper reflects on the way the rule-based approach to determining genre in the manual content analysis relates to the training of an automatic classifier based on machine learning techniques.

In order to link the articles described in the existing metadata set to the corresponding KB data, we first created a number of rules to find the most promising candidate links for each item in the original data set, based on the position of the article on the page, its size, and the presence of images and quotes. Since these rule alone turned out not to be sufficiently accurate, a simple classifier was trained to select the best link from the candidate set, if any, based on features such as the difference in size and number of images present between the article as described in the original data set and the article as found in the KB repository, as well as author mentions and subject matter, amongst other features. By only accepting links predicted by this classifier with a relatively high confidence value approximately 50% of all articles could be automatically linked, with an error rate of 0.5%. Some genres were underrepresented in the automatically linked set and were manually expanded upon.

The data set resulting from phase 1 was then used to create a training and test set for the actual genre classifier. This, again, involved taking several steps: first, the OCR for the articles in the set was retrieved and cleaned of quoted text by means of regular expressions. Next, the remaining text was pre-processed with the Natural Language Processing software package Frog, performing tasks such as segmentation, tokenization, and part-of-speech tagging. From the resulting annotated text, the relevant features for each article were calculated, such as number of words, number of sentences, number of direct quotes removed, and, most importantly, number of adjectives and various types of pronouns found in the text. These features, together with the existing genre labels were finally used to train a Support Vector Machine to choose one of eight possible genres for each article, ranging from news report and interview to news analysis and opinion article.

The initial results we obtained with this classifier were quite promising. Our first attempt resulted in an accuracy score of 58%, with the default accuracy by predicting the majority class or genre being 46%. The confusion matrix made from the predictions provides important information about which genres are most difficult to predict and what mistakes are most commonly made. This information can help us to fine-tune the existing features. Moreover, we have not yet implemented all the textual features that typify the different genres, such as named entities occurring in the text, sentiment, or self-classification to name only a few. Finally, we will compare the results of different algorithms, including deep learning approaches. Based on this, we expect to be able to improve these initial results in the coming months and present our final results in more detail at the conference.

Genetic Editions to the Extreme? Conserving Historical Text Generators

Claus-Michael Schlesinger
claus-michael.schlesinger@ilw.uni-stuttgart.de
Universität Stuttgart, Germany

Short Description

My talk will focus on the problems and possibilities of conserving historic text generators, 'historic' meaning roughly 1950-1970. For this purpose, I will develop the scientific interests in these generators either from the perspective of literary history and from the perspective of the history of knowledge, since many of the text generators in question were connected explicitly to scientific interests.

A system for conserving and editing historic text generators, that will enable researchers from both of these fields to access historic text generators in order to study their esthetics and functioning needs, in orderto take into account not only the generated texts, but also the generating texts, meaning software and prerequisites such as flowcharts. In my talk, I will focus on the materiality and the potentiality of the historic text generators in order to propose a platform solution that should enable scholars to edit (and publish) historic textgenerators.

Full Abstract

In their manifesto Zur Lage (Bense and Döhl (1964)) (State of Things) Max Bense and Reinhard Döhl name several tendencies of contemporary literature. The sixth and last point of their list calls on a cybernetic and material poetry ("kybernetische und materiale Poesie"). Historically and biographically, Bense and Döhl were placed at one of the centers of concrete poetry and concrete art (Stuttgart, Germany), and their manifesto reflects the artistic and academic developments made in these areas. But already in 1964, when Bense and Döhl published their manifesto, experiments had taken place that had taken the notion of a cybernetic poetry quite literally, using computers and software to generate literary texts. (Strachey Okt. 1954; Lutz 1959; Levin 1963; Gunzenhäuser 2004; Link 2004) The automatic generation of texts by way of combining syntax, vocabulary and a (pseudo) random generator that serves to fill the syntax positions with proper words from the vocabulary has a history dating back to the 17th century. However, it was the use of computers that prompted artists and researchers to expand their experiments and develop complex setups applying hundreds of syntactical structures and bigger vocabularies (as did, for example, Stickel [1967]).

The research on early text generators has focused on biographical data and the literary history of automatic text generation (Bülow 2007), the autoreflexivity of digital texts (Cramer 2003) and the genealogy of text generating systems (Link 2004). A literary and cultural history of text generators needs to take into account not only the texts that were produced, but also the modes and methods of production. In my talk, I will argue that in order to understand the history of automatic text generation, we need to join these different perspectives and research either the generated texts and the modes and methods of text generation.

Now the first problem when dealing with text generators (and the texts generated with them historically) is the availability of the material. Only a small fraction of historically generated texts has been published, and in most cases the documentation of the conceptual and technical setup is only partly available through publications, not to mention the actual code that was used to produce the text in the first place. This is due to the fact, that literary scholars have tended to ignore texts of this kind – that is, experimental text which barely fulfills any definition of poetry – and are only beginning to recognize them as a certain type of literature in its own kind. The second reason for a newly developed recognition for early text generation experiments is the fact that automatic text generation has become ubiquitous in our time, from simple twitter bots that employ the same methods as the early text generators (meaning simple syntactical structures filled with randomly chosen words), via the modern ELIZAs of contemporary electronic assistant systems, to complex machine learning algorithms that synthesize Shakespearean plays. (Goodwin 2016)

So in order to further research on early text generators, the multiple dimensions of text generators will have to be made available to researchers from all fields concerned with the history of automatic text generation. Since I am, by profession, a philologist, my approach is limited to the document side of things and does not consider hardware conservation or emulation.

Documents connected to text generators comprise flowcharts, punched tape, source code data on magnetic memory, print-outs, project documentation in various paper formats. For a digital representation, these materials can be digitized either in graphical or in textual format. Graphical representations can be annotated with their respective metadata describing their material, function, authorship etc. As for the texts contained in a text generator as a historic object, we are dealing with three different kinds of texts:

- texts that have been generated
- texts that have been used to generate texts (mainly software)
- texts that could have been or can potentially be generated (the full outcome of the underlying algorithm)

Texts in groups 1 and 2 are connected in a genetic way. If we take the Stochastic Texts by Theo Lutz and Rul Gunzenhäuser (Lutz 1959) as an example, we can see that there is a published version of the generated texts and a raw version (published in Büscher, 2004). The differences between these versions are significant. From a text-genetic perspective, these differences lead to the production of the texts or, in other words, the execution of the underlying program. The execution of the program leads to the implementation of the program or the source code, the source code leads to the conceptual implementation of the algorithm (e.g. flowcharts) and thus to the abstract underlying algorithm.

Thus, a genetic perspective on text generators leads not only to the raw version of the output of the computer, but to the implementation of the algorithm in source code as well. The title of my talk searches to reflect this notion of text genesis, because the link between source code and output is not a certain similarity between two texts, but a functional, algorithmic connection. I think that problematizing this kind of functional genetic connection can also be fruitful for philology dealing with texts where computers don't generate all of the text, but help in generating certain features of the text. In order to describe and show this kind of connection in different text generators, it will be necessary to develop standardized notions for annotation schemas (Currently, the annotation of source code is not part of the TEI Guidelines (TEI-Consortium and Lou Burnard 2014)

Finally, studying the poetics of a text generator might also mean to study more generated text than is (historically) available. A representation of a text generator thus not only should comprise the source code itself, but also the possibility to run the algorithm in order to generate some of the potential texts. The best solution would be, of course, to run the code on the historic machines it was developed for. Not only would this repeat the original experiments, it would also hopefully reproduce the glitches that can be seen in the raw output that has been preserved and archived. (Büscher 2004) However, such a procedure would be way too costly. An easier way is to implement the reconstructed algorithm in a modern programming language and to offer researchers the possibility to run the code without being forced to undertake major retrocomputing tasks just in order to gather some more textual outcome.

Since this is a work in progress, I am confident that by August 2017 I will be able to outline not only the problems, but also some solutions for implementing a platform and database to preserve and present historic text generators.

Introduction

Weiso(衛所制), which means "guardhouse", is one of the military units of the barracks used by the Chinese dynasty Ming (1368-1644) to maintain peace throughout its empire. WeisoEvent is a web-based digital humanity research tool targeting Ming Weiso events recorded in Ming Shilu, which contains the imperial annals of the Ming emperors. WeisoEvent is composed of two parts: (1) an event type classifier that categorizes paragraphs according to their event types; (2) an analytics tool that shows (1)’s result, markups named entities, links guard mentions to Academia Sinica’s Chinese Civilization in Time and Space (CCTS) spatial-temporal platform, and provides four visualization functions. Historians can use this tool to search for specific event types and gain insight into the relationship between particular guards and those event types, not only improving the efficiency but still maintaining the quality of research.

Event type classifier

Normally, one would develop a supervised-learning-based text categorization system to classify paragraphs into different event types. This involves defining a set of categories and annotating example texts for each category. However, lacking the human resources needed for such a task, we use unsupervised text clustering, which groups paragraphs into clusters by event type, to generate categories and their corresponding paragraphs for training an automatic event classifier. Although the results are not as accurate as those of pure supervised text classification, this hybrid approach is an acceptable tradeoff.

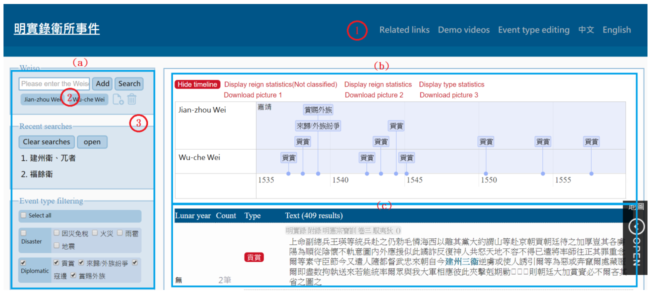
In clustering algorithms, each paragraph is represented as a vector. In previous studies, paragraphs have been represented using the vector space model (VSM), which represents each text as a feature vector of terms. However, this approach loses the ordering and ignores semantics. Yet another representation scheme inspired by word2vec is the “Paragraph Vector” proposed by (Le and Mikolov, 2014), an unsupervised framework that learns continuous distributed vectors for pieces of text. In their model, entire paragraphs are represented as vectors. The vector representation is trained to predict the words in a paragraph. More precisely, they concatenate the paragraph vector with several word vectors from a paragraph and predict the following word in the given context. Le’s Paragraph Vector model has many advantages. First, it is mostly unsupervised and works well with sparsely labeled data. Second, it is suitable for text strings of various lengths, ranging from sentences to whole documents. Finally, it can overcome many weaknesses of the bag-of-words and bag-of-n-grams models. Because it does not suffer from data scarcity and high dimensionality, it also preserves the ordering and semantic information.

In summary, we propose a classification method which is based on clustering. First, we employ a named entity (NE) recognizer to label texts. Second, we train a paragraph vector model to represent paragraphs as vectors. Third, we cluster paragraphs with length <40 characters. Finally, we use the clustering results as gold-standard categories with which to train a support-vector-machines classifier to predict other paragraphs' categories.

We compare our method with the state-of-the-art paragraph clustering method using continuous vector space representation proposed by (M. Chinea-Rios et al., 2015). They use word2vec to learn word vectors and represent each sentence by summing the vectors of the words in that sentence. Like Chinea-Rios et al., we use the k-means algorithm to cluster vectors. We set the number of clusters to 68. We refer to the evaluation measures used in (Le and Mikolov, 2014). We generate sets of three paragraphs: two with the same event type and one with a different event type. Each set is referred to as a paragraph triplet. The distance between the two vectors with the same event type should be closer than the distance between either of these two and the unrelated one. We collect 923 paragraph triplets and compute the accuracy. Our best configuration that combines word dimensions and named entity dimensions to generate paragraph vectors achieves an accuracy of 62.49%, outperforming Chinea-Rios et al.'s pure text-clustering approach (M. Chinea-Rios et al., 2015) by 24.65%.

Analytics tool interface

WeisoEvent groups paragraphs with similar subjects into clusters automatically and each cluster is named manually according to the main subject of its paragraphs. Clusters with related topics are grouped into broader categories for search convenience. For example, we group "earthquake", "conflagration" and "hailstorm" into the event category "disaster". Users can modify event category titles by clicking a button on the top-right of the webpage (see Fig. 1, [1])



Lunar year	Count	Type	Text (409 results)

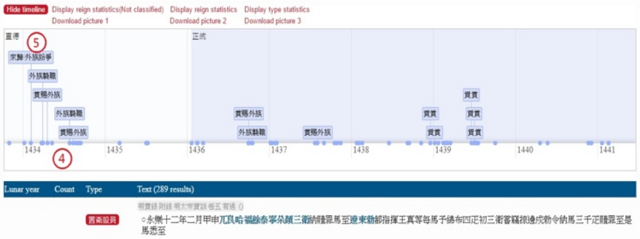
Figure 1. System interface.

Fig. 1 shows our research tool webpage, which consists of three main windows: (a) search parameters, (b) search result visualizations, and (c) search results snippets.

1. Search parameters: Users can search for one or more guards by typing the name into the search box (Fig. 1, [2]). For convenience, a user may also import a guard list by clicking the "import" icon (Fig. 1, [3]). Notably, if two guards are queried, their event timelines are displayed in parellel, like Jian-zhou (建州) and Wu-che (兀者) guards shown in window b. After at least one event category is selected, the search results are shown in windows b and c.
2. Search result visualization tools: In window b, users can select among four visualization options at the top of the frame. Option 1 hides or shows an event timeline of the search results on the page. When the event timeline is enabled, event-type labels corresponding to each retrieved paragraph are displayed chronologically on the timeline. For reference, the timeline shows the CE year at the bottom of the window (Fig. 2, [4]) and the name of era, which usually corresponds with the reigning Ming emperor, at the top (Fig. 2, [5]). When a user clicks on an event icon in the timeline, the corresponding text snippet is displayed in window c, highlighted in yellow (Fig. 2). Figure 3 takes Jian-zhou guard (建州衛) as an example to depict options 2 to 4. Option 2 is the bar chart. Each bar corresponds to a Chinese era name and represents the total number of paragraphs for the three selected event types in that era. Option 3 shows each bar sub-divided by color to show the distribution of paragraphs of each event type ("come over and pledge allegiance"/ "reward alien"/ "tribute-reward") in each era. By clicking Option 4, a pie chart shows the distribution of the three selected event types in the entire dataset. The slice for each event type is labeled with the number of paragraphs of that event type and its percentage of the total. These data visualizations offer historians a quick statistical overview of selected event types.



Lunar year	Count	Type	Text (289 results)
		置衛設員	明實錄 附錄 明太宗寶訓 卷五 宥過 () ○永樂十二年二月甲申兀良哈福餘泰寧朵顏三衛納贖罪馬至遼東勅都指揮王真等每馬予綿布四疋初三衛嘗竊掠邊戍勅令納馬三千疋贖罪至是馬悉至

Figure 2. Event timeline

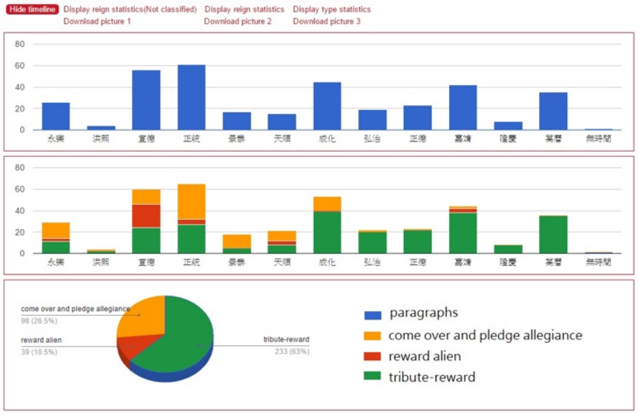


Figure 3. Data visualization options

3. Search snippets: Text snippets of paragraphs related to the searched event types are displayed in window c (Figure 1, (c)). The results are organized in a table with columns (L-R) showing time, number of paragraphs, event type, and related paragraph snippets. All guard mentions in the texts are highlighted and linked to Academia Sinica's CCTS-API Map Service . When a user clicks on a guard link in the text, the guard's location will be shown on a map of Ming China in a pop-up window, see Fig. 4. It shows the locations of Wu-che guard (兀者衛) and Jian-zhou guard (建州衛) in the same map.

Finally, we conduct a case study targeting Jurchens subordinated garrisons, including Wu-che guards (兀者諸衛) , Jian-zhou guards (建州諸衛), Mao-lian guard (毛憐衛) by using the proposed tool to obtain statistics regarding tribute event types.

We compare our event classification results with Cheng's study (N. Cheng, 2015), which used Ming Shilu as the source to investigate the tribute events during Yongle (永樂), Hongxi (洪熙), and Xuande (宣德) periods. We regard the paragraphs categorized as "tribute-reward", "come over and pledge allegiance", and "reward alien" event types as those potentially illustrating tribute events and manually check them. For Wu-che, Jian-zhou, and Mao-lian guards, 69, 86, and 40 paragraphs are identified as the above three types, respectively. Among these paragraphs, 66, 77, 37 are correct, which are close to the numbers of tribute events in Cheng's study for these three guards (60+, 70+, 30-). This study was done within 16 man-hours. These preliminary results are consistent with Cheng's manual analysis results and show that our tool not only helps historians study Weiso events more efficiently but also keep the quality.

VIA is a mobile art project combining video-dance, computational music and architecture. Its main goal is to endow public locations of downtown Rio de Janeiro with video-dance and music, accessed through locative media (smartphones or tablets). The VIA website is the main way of learning about the project, as it provides all the necessary information, including a map that indicates the specific locations where users are able to access the multimedia pieces of the project. Two "Vias", or routes, can be selected on the map, "Via 1" or "Via 2". Each of them is a distinct route on the map linking specific locations according to landscape features (as we shall explain in the next section). Although the project suggests experiencing the work according to these two routes, each viewer can decide how and when they are going to do so. There is not only one precise route to experience the project: some may decide to access the content in a single location and then leave, whereas others might want to visit all the locations creating their own routes from one point to another. Besides the website, the public can also learn about the project through printed maps distributed in Rio de Janeiro's downtown areas where VIA is located. The distributed maps are the same as the website's, except for the fact that there is not a distinction between Vias 1 and 2. It also includes the addresses of the locations in order to guide viewers through the project. The main technology employed to access the project is the QR Code. QR Code is a specific two-dimensional barcode target that can be read by barcode readers and phone cameras. Once viewers decide on a location to start, they must walk to it, where they will find QR Codes on walls, utility poles, litter bins and others. With a QR code reader application, they must frame the QR barcode and wait for the content to be loaded. Summarily, any user equipped with a tablet or smartphone with an Internet connection has free access to experimental multimedia pieces of video-dance and music while moving through specific points of Rio de Janeiro. The multimedia content resulted from the collaboration between João Queiroz (artistic director), Daniella Aguiar (dancer and choreographer), Luiz E. Castelões (music composer), Adriano Mattos Corrêa (architect), Guilherme Landin and Claudia Rangel (video-makers), and Alfredo Suppia (video editor). Each multimedia product was the result of artistic investigation taking place between dance, music, and the architectural richness of Rio de Janeiro urban space, providing pedestrians with an experience that superposes "navigation" through the city and contemporary dance and music. The sounds/music accompanying these videos derive from CAC (Computer-Assisted Composition), CGA (Computer-Generated Assistance), and Sonification – related approaches. They consist of image-to-sound conversions using patches developed in OpenMusic. These conversions employ, as input images, a collection of photographs previously taken from the locations where the dancing took place. The compositional action involved consists mainly of normalizing the xy axis data extracted from the contours of these images within audible ranges. There has been no further compositional manipulation of the input data – such as displacement, editing, looping, etc. Two types of location were chosen to create the "vias". In the first type, the chosen locations, although varying from open spaces, as squares, to narrow streets, share the property of being places with ongoing movement of people. The second type is characterized by building interspaces, independent of other architectural characteristics. The dance movements were developed in strict relation to the chosen spots. In this way, the dance is created in relation both to the buildings and to the passing people. The audio-visual language is based on discontinuous approaches and withdrawals from the "theme" (performer), which irregularly repeats short, alternated and cyclic movements. The video editing is rigorously metric and based on the organization of parts in regularly juxtaposed sequences. This method fixates and highlights invariant properties of the landscape algorithmically translated by the music. One of the project's main features is that viewers can access the pieces at the exact same location where the video and the music were created. As a result, mobile technology users connected to the Internet are able to access the multimedia pieces of the project, experiencing environments in which information and virtual objects "overlap" physical reality.

Getting Medieval: Open Access and Networked Pedagogy

Suzanne Akbari
s.akbari@utoronto.ca
University of Toronto, Canada

Alexandra Bolintineanu

alexandrabolintineanu@gmail.com
University of Toronto, Canada

Getting Medieval: The Many Middle Ages is an undergraduate course, a digitally-inflected introduction to the global Middle Ages. *Getting Medieval* functions as an experiment in networked pedagogy, drawing on the expertise of faculty researchers, curators, and digital scholarship specialists. Students read medieval texts, handle related medieval artifacts from the University's special collections, and curate digital collections and exhibits that bring together texts, artifacts, and digital repositories from around the world. Students also attend biweekly guest lectures by faculty researchers and cultural heritage professionals. Our course is predicated on open access--to a wider Middle Ages than the traditional western European canon reveals; to open-source, open-access platforms for public scholarship and digital collections; to a technical infrastructure open to members of the university community; and to the fragile artifacts of the medieval past from the vaults of local cultural heritage institutions.

We conceived the course as a series of moments in time and space, moments defined by literary texts and related physical objects—when possible, objects from the University of Toronto's Malcove Collection, which students can visit in person. For example, the unit on Geoffrey Chaucer's Canterbury Tales invited students into fourteenth-century England, along the road from London to Canterbury. Students learned about medieval pilgrimage and religious practices around relics. In this context, they encountered Chaucer's pilgrims—and especially the false-relic-peddling Pardoner. And in this context, too, they touched and handled a twelfth-century French reliquary from the University of Toronto's Art Centre. The course focuses on a wide variety of times, places, and literary texts, beyond the traditional western European focus of Medieval Studies: from eighth century Anglo-Saxon England and the Old English *Beowulf* to tenth century medieval Spain and the interweaving of Jewish, Muslim, and Christian theological and poetic traditions in the region of Al-Andalus; from the eleventh-century Japanese imperial court and Murasaki Shikibu's courtly *Tale of Genji* to the twelfth-century Anglo-Norman court and the lays of Marie de France; from the cultural crossroads of the Ethiopian capital of Axum in the thirteenth century to the cultural crossroads of the French capital of Paris in the fourteenth; from the East-West journeys of Asian, Middle-Eastern, and European travelers along the Silk Road, to the journey of Geoffrey Chaucer's pilgrims from London to Canterbury. To do these varied traditions justice, we invited guest speakers to introduce their research. In one class, students listened to an Old English lexicographer talk about linguistic archaeology at the Dictionary of Old English. In another, they learned about a digital collection of medieval Tibetan letters, and they turned the pages of a twentieth-century Tibetan book which maintains medieval book forms. In yet another, students experienced a lecture that turned into a performance of medieval drama. The lectures provide access not only to the usual undergraduate curriculum, but to a range of faculty-led research projects that showcase the range of Medieval Studies at Toronto.

The digital inflection of the course is twofold. First, students examine how the times, places, texts, and things we study are represented in digital projects and repositories, from the Dictionary of Old English to the International Dunhuang Project. Second, students are invited to create public-facing scholarship themselves: After they visit the secure storage spaces of the Malcove Collection and receive the curator's guidance on the care, handling, and cultural context of artifacts, students handle medieval artifacts; study them in the context of our local collection and of digital repositories around the world; and produce a public, curated digital collection and exhibit, linking the artifact to the course's thematics, in the open-source content management platform Omeka. In so doing, students practice close reading and slow looking, examining an object in cultural and literary contexts. They also learn about digital collections—from the digitization of materials to data curation and digital preservation—and about scholarly communication possibilities in the digital age.

We designed our digital assignments with access in mind. The students' initial contact with the secure vaults of the Malcove Collection offered hands-on, immediate, physical access to the artifacts—and included a discussion on the kinds of information such access provides, information unavailable in a digital medium. The software platform Omeka itself is free, open-source, with significant traction in DH pedagogy. Our hosted Omeka instances allow students to complete the work even if they only have access to public university computers. Our tutorials guide students through the work in interactive workshops conducted in university computer laboratories, ensuring that students without a laptop, or without prior technical experience, are able to complete their work in a supportive environment, with help close at hand. But this level of access requires significant logistical work and infrastructure. Students have access to faculty research projects thanks to the Centre for Medieval Studies' network of scholars. Students are able to use university laboratories because we make arrangements in collaboration with digital scholarship librarians to provide access to this portion of UofToronto's computing infrastructure. Students are able to experience relevant artifacts from the Malcove collection so closely because of a course-long collaboration between its Collections Manager, Heather Pigat, and the course instructors.

Thus *Getting Medieval* functions as an experiment in networked pedagogy. Biweekly guest lectures, robustly integrated into the curriculum, invite a network of faculty researchers and cultural heritage professionals into the undergraduate classroom; and the open access requirements of our digital projects draw on the institution's physical and human infrastructure—from special collections of medieval objects to computing facilities; from curators to medievalists to digital scholarship specialists. As we invite our students on a time-travelling journey across the global Middle Ages, we rely on a network of guides to open points of access along the way.

Coffee Zone: Del cafetal al futuro / From the coffee fields to the future

Mark Anderson
mark-anderson@uiowa.edu
University of Iowa, United States of America

Hannah Scates Kettler
hannahskettler@gmail.com
University of Iowa, United States of America

In the last decade, the number of coffee farms in Puerto Rico has shrunk from around 11,000 to nearly 4,000. Economic and climate conditions, as well as the increased migration of young people to the more cosmopolitan coastal areas in pursuit of education, have resulted in significant changes to the island's coffee-growing regions. These changes, especially with regard to linguistic characteristics of the coffee growers themselves, have been the subject of a multi-year study by University of Iowa Linguistics Professor Julia Oliver Rajan.

The Digital Scholarship & Publishing Studio at the University of Iowa collaborates with faculty and students on the digital design, implementation, and circulation of their research. The Studio embraces scholarly creativity and encourages interdisciplinary research and multiplatform circulation. In this manner, the Studio helps scholars tailor the presentation and application of their research to a variety of audiences.

Together with Professor Oliver Rajan, the Studio has created a unique bilingual (in Spanish and English) digital archive of oral history videos – Coffee Zone: Del cafetal al futuro / From the Coffee Fields to the Future documents a vanishing dialect of Spanish spoken in the mountainous coffee growing regions of Puerto Rico. Currently consisting of over 600 short video clips in 16 topical categories, the archive demonstrates how rapid migration to the cities has altered the power structures of coffee plantations, the role of women and young people, and the new landscape of coffee production. The site can serve as a template for other researchers who are documenting similarly endangered languages or dialects in other parts of the world.

We propose to present a poster at DH2017 reporting the progress and challenges of this digital humanities project, how it acts as a resource for scholars and students in a wide variety of disciplines (ecology, horticulture, psychology, and obviously linguistics, just to name a few), and the upcoming features we are working to implement. We will outline the upcoming features and how this specific project, though currently focused on linguistic shifts in the coffee zone, applies to much larger, global concerns of globalized economies, climate change and the loss of language as it relates to cultural identity.

Although the videos are now freely available worldwide, accessibility is limited because they are neither transcribed nor translated from their original Spanish. Closed captions in the videos would enhance their usefulness to a wider audience, but a major challenge lies in the very nature of the oral histories – the unique dialect of Spanish spoken by the interviewees. To overcome this, we look to expand the project by collaborating with the University of Puerto Rico, where they would contribute to it by assisting with the tasks of transcription, translation, and caption encoding as well as test the site in their courses. Another feature we look to add is an interactive map showing the geographic areas affected by these changes, which would function as an additional access point to the videos themselves.

Distant Seeing TV

Taylor Arnold
tarnold2@richmond.edu
University of Richmond, United States of America

Lauren Tilton
ltilton@richmond.edu
University of Richmond, United States of America

We present work on *Distant Seeing TV*, which applies computational techniques to the study of television series. Our initial set of interest consists of five American sitcoms spanning the 1950's through the 1970's. In order to focus the academic questions that we are interested in exposing, all of the selected shows feature leading women characters and have previously been the topic of academic studies. The poster will outline the kinds of academic questions we hope to answer with our study, the computational methods currently available for answering these questions, our novel extensions of these methods, and some initial results.

The project *Distant Seeing TV* brings the approach of Moretti's "Distant Reading" and Manovich's cultural analytics to the analysis of a large corpus of moving images (Moretti 2013, Manovich 2001). Given that long-running television series broadcast hundreds of episodes and the major networks run dozens of series each season, previous studies, including (Baughman 1993), (Dow 1996), (Spangler 2003), (Morely 2003), have largely had to rely on a close analysis of a small subset of series, episodes, and even scenes. Our project seeks to augment these approaches with computationally-driven analyses that can curate and aggregate the contents of tens of thousands of hours of television programming. To do this, we extract features such as the placement and identities of faces in the shot, as shown in Figure 1, and the time codes for laughter, music, and scene changes as well as the identity of scene locations, as seen in Figure 2. There has been relatively little work done on an aggregate analysis of a corpora of moving images. Noticeable exceptions include *Cinemetrics* (Tsivian and Civjans 2011), which focuses on average shot length in cinema, and the *Arclight Guidebook to Media History and the Digital Humanities* (Acland and Hoyt 2016). Our work extends these to a much wider set of metrics and centers on issues specific to television in contrast to those of film.

Our work attempts to address several types of questions of interest within television studies. These include: Are women characters seen entering a scene more frequently than men? Which characters tend to walk in front of other characters? Does the typical sequence of locations change throughout the run of a show or across different shows? How can we best characterize the narrative arc of an episode? These questions address issues of auteurship, gender, race and narrative in TV.

The initial corpus we are working with includes a diverse set of series with women lead characters that span the 1950s through 1970s. They include a mix of episodes filmed in black and white, in color, with a multiple-camera set-up, with a single camera set up, and from all three major networks:

- I Love Lucy, 1951-1957 (b/w; multiple-camera; CBS)
- The Donna Reed Show, 1958-1966 (b/w; single camera; ABC)
- Bewitched, 1964-1972 (b/w to color; single camera; ABC)
- I Dream of Jeannie, 1965-1970 (b/w to color; single camera; NBC)
- The Mary Tyler Moore Show, 1970-1971 (color; multiple-camera; CBS)

Focusing on a small but diverse set helps in the early stages on this project as we adaptively learn what tools and techniques are most interesting and explore how these methods intersect with current scholarship.

There has been a rapid rate of advancement in modern computer vision techniques over the past decade, which has been particularly driven by the use of deep convolutional neural networks. Given their novelty, there are limited computer vision tools that can be used directly out of the box on a new problem domain. Much of our work on the project has been focused on building a tool set specifically engineered for analyzing television, with a particular focus on parsing black and white images. We will release these tools as an open source package, with wrappers written in python, once it becomes stable enough to be used by other researchers. Techniques that have or will implement include facial detection and recognition (Sun, et al. 2015), scene break detection (Kar 2015; Kumar, Gupta, and Venkatesh 2015; Pulvar 2015), scene classification (Cheng 2015), dialogue disambiguation (Cervone 2015), speech detection (Sanders, Taubman, and Lee 2015), audience and laugh track detection (Cosentino 2015; Joshi 2016), music segmentation, camera angle detection, and camera selection detection (Nadimi and Bhanu 2004). In all of these cases, training specifically on historical television data has yielded significantly better results that models trained on generic corpora.

The study of television has often been downplayed in favor of textual sources and feature-length film. As described in (Fiske 1978): "Television suffered categorical disadvantage in repute ... its characteristic was oral not literate, whereas 'dominant culture' ... was militantly committed to print-literacy and the values associated with that." From the 1950's onward, however, television has arguably served as the dominant source of mass entertainment in the United States. By 1959, over 83% of households in the US owned their own television set (Baughman 1993). This is not to say that there has been no substantive research in television studies. In fact, there is a large set of prominent examples, including (Baughman 1993), (Dow 1996), (Spangler 2003), (Morely 2003), and many more. Given that long-running television series broadcast hundreds of episodes and the major networks run dozens of series each season, these studies have largely had to rely on a close analysis of a small subset of series, episodes, and even scenes. Our project seeks to augment these approaches with computationally-driven analyses that can curate and aggregate the contents of tens of thousands of hours of television programming.

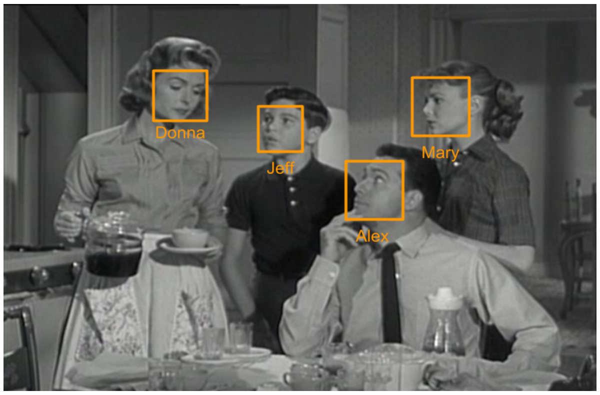

Figure 1. An example of face detection and disambiguation from a still image taken from The Donna Reed Show. Tracking these over the course of a scene and episode reveal characteristics of how characters interact and describe the narrative flow of the series.

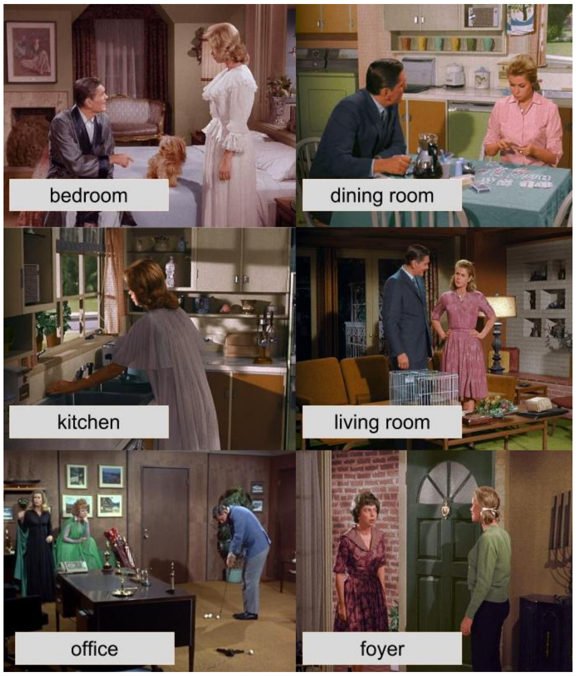

Figure 2. An example of scene classification from Bewitched. Each still image from the episode is tagged with the description of the sets on the sound stage. Following the progress of these over the course of the episode can serve as a way to compactly describe and aggregate the narrative arc of an episode. Comparing across episodes, seasons and shows reveals similarities and differences across the various series of interest.

School of Humanities and Social Sciences,
Indian Institute of Technology Indore, India

This poster offers a concise working plan of a digital project titled *1947 Partition on the Margins: The Untold Testimonies of Sikh, Bahawalpur and Marwari Communities*. The project aims to collect undocumented narratives of many

'Punjabi' and 'Rajasthani' communities who migrated from villages in current Eastern Pakistan to villages in the current Western India during the 1947 partition. The primary objective of the project is to create an open access visual and narrative based digital archive of partition and post-partition testimonies developed through audio-video transcripts and photographs. The audio-visual transcripts will be collected through personal interviews of the partition witnesses, their families and subsequent generations. These interviews will take place on-site in their villages. This population mostly consists of Sikh, Bahawalpur and Marwari communities who travelled comparatively short distances during partition, settling in the nearby villages close to the border in Indian states of Rajasthan and Punjab. The geographical distance travelled by these communities towards Indian villages was only about 40 to 50 KM. However, the spatial definitions changed and any hope of revisiting the ancestral homeland was shattered with the newly constructed international border.

These are a few minority communities residing in small villages whose partition experiences are not traced in public memory or documented in any literature, primarily because their journey of migration was relatively hushed and non-violent. However, the geo-political movement from one place to another brought larger social, cultural, political and economic challenges in the post-independence India for families in these many communities. They migrated from one small village to another leaving behind whatever geographical, economical and cultural assets that belonged to them. Even after almost 70 years of partition in 1947, families in these communities are struggling to own lands of their own. The generation that witnessed the partition of 1947 is disappearing and will not be there after next 4 to 5 years. Therefore, it becomes an obligatory task to document the narratives of a traumatic historical event that completely changed the flow of history.

The subsequent generations of these families who migrated to India continue to face economic and cultural challenges. The nostalgia of not being able to visit their ancestral homeland disturbs the process of connecting with their current homeland. Therefore, this project aims to contextualise these first-hand audio-video interviews and photographs into narratives that will provide an influential palimpsest of history and the contemporary cultural and political state.

There are several ongoing digital projects that contextualise historical events into narratives such as *1947 Partition Archive*, *1984 Living History*, *Kashmir Oral History*, *Indian Memory Project* and *Holocaust Memorial Museum*. The memory projects on the 1947 partition such as *1947 Partition Archive* mostly record stories that are often (rightly so) narratives of violence and bloodshed. However, there is gap in existing literature and database that do not document less violent partition experiences of a large population that mostly live at the western Indian border. The aim of the current project is to document those unheard communities which escaped immediate violence but continue to suffer the residual pains of geo-cultural and economical traumas in post-partition India. The poster also offers a framework of methodology to be followed for developing the project. The methodology involves collection of data by visiting the villages, audio-video interviews with families, collecting photographs and letters, transcription and description of interviews and contextualising photographs and letters in narratives. The development of final testimonies achieved through these working stages will be developed into an open access website, hosted through KSHIP (Knowledge Sharing In Publication) which is a multilingual academic publishing project at IIT (Indian Institute of Technology) Indore, India.

Athar: Numérisation, indexation et mise en ligne enrichie des bulletins du Comité de conservation des monuments de l'art arabe (1882–1953)

Hélène Bégnis
helene.begnis@persee.fr
Université Lyon, ENS de Lyon, CNRS, France

Antonio Mendes da Silva
antonio.mendes@inha.fr
INVISU, Institut National d'Histoire de l'Art, France

Le projet Athar (de l'arabe traces ou empreintes, et par extension monuments ou antiquités) met à disposition, en open access, l'intégralité des travaux du *Comité de conservation des monuments de l'art arabe* (1882-1953), instance créée au Caire pour inventorier, décrire et restaurer les monuments islamiques puis coptes d'Égypte. Sur le modèle des *rapports de la Commission des monuments historiques en France*, cette publication annuelle, rédigée en français, aujourd'hui éteinte et libre de droits, se compose de 41 volumes publiés au Caire entre 1882 et 1953, totalisant 8 000 pages et près de 800 planches. Ce corpus rassemble parfois l'unique documentation encore subsistante sur des monuments disparus, très dégradés ou radicalement transformés. Par ses illustrations, il se trouve en relation avec les riches fonds de la photographie commerciale présente au Caire à partir de 1860, diffusée de façon croissante sur Gallica et Europeana.

Les partenaires

Ce projet est le résultat d'une collaboration fructueuse entre trois structures du monde scientifique et universitaire français : le laboratoire InVisu, l'Institut français d'archéologie orientale et Persée. La complémentarité des expertises de chacun de ces partenaires a été essentielle pour mener à bien ce projet. Le laboratoire InVisu, grâce à son savoir-faire documentaire, a pris en charge la structuration fine du corpus et l'indexation des toponymes à l'aide du *Cairo Gazetteer*. Ce référentiel multilingue (français, arabe, anglais) permet d'identifier, de décrire et de localiser finement les 600 édifices classés du Caire au titre de monuments historiques en proposant les variantes orthographiques de ces toponymes. L'IFAO a permis la complétion de la collection en prêtant les volumes manquants et a apporté ses compétences sur la toponymie et la cartographie égyptiennes. Persée, grâce à son expertise de plus de 10 ans en matière de numérisation, d'océrisation et de diffusion du patrimoine scientifique, a mis au service du projet sa plateforme technique (JGAlith : application intégrée et complète, développée par Persée, qui permet à l'ensemble de ses partenaires impliqués dans le processus de traitement des collections de communiquer et de partager les informations apportées par chacun) et ses ressources humaines assurant ainsi la gestion de l'ensemble du cycle des documents (dématérialisation, documentation, diffusion web, sauvegarde et archivage pérenne).

Technologies et formats, usage du Linked Open Data

Les technologies et formats utilisés reposent sur les normes et les standards en vigueur dans le contexte de l'open access et de l'interopérabilité. Les métadonnées générées par la structuration du corpus sont encodées au format XML selon les schémas Dublin Core, MarcXML et MODS. Le texte intégral issu de l'OCR non corrigé est disponible selon le schéma TEI et l'ensemble des données est décrit et organisé dans un container XML au format METS. Le contenu du *Cairo Gazetteer*, déployé grâce à Ginco (outil de gestion de référentiels terminologiques), est mis à disposition de la communauté des humanités numériques par le biais du format SKOS. Il offre une solution innovante pour résoudre les difficultés liées à la translittération des toponymes arabes.

Illustration 2. Les données du Cairo Gazetteer encodées en RDF

Des liens vers deux référentiels disponibles au niveau international ont été insérés dans les données de structuration du corpus : IdRef pour les auteurs et le *Cairo Gazetteer* pour les édifices. Ces liens permettent de déduire des alignements vers des ressources extérieures complémentaires telles que data.bnf.fr, DBpedia, les Subject Headings de la Library of Congress et GeoNames. Le développement et l'implémentation par l'équipe informatique de Persée d'un module spécifique dans la plateforme de JGALITH a été nécessaire pour réaliser cette étape.

COMITÉ DE CONSERVATION
DES
MONUMENTS DE L'ART ARABE

QUINZIÈME RAPPORT DE LA DEUXIÈME COMMISSION

EXAMEN
De la mosquée El-Almi (à Kalaat-el-Kabch), de la mosquée Khoschkadam (au quartier Khalifa) et de la mosquée Mehmendar (à Darb-el-Ahmar).

Illustration 5. Affichage sur le portail www.persee.fr

A l'horizon 2017-2019 un site corpus sera développé par Persée faisant ainsi évoluer son offre de services. L'ensemble des données produites et agrégées dans le cadre du projet Athar sera intégré dans un écosystème plus large pour offrir une information plus riche, plus complète et centralisée pour l'utilisateur du site dédié. Des pages composites construites à partir des données produites par la chaîne Persée et celles récupérées grâce à l'alignement avec les référentiels extérieurs sélectionnés seront aussi développées. Elles viendront compléter l'éventail des fonctionnalités de navigation et d'exploration (index auteur, table des matières, références croisées, table des illustrations) déjà mis en œuvre dans le portail Persée. Parallèlement à la diffusion web, une exposition des données par le biais d'un entrepôt OAI et d'un SPARQL endpoint sera également déployée.

Mapping Borges in the Argentine Publishing Industry (1930–1951)

Nora C. Benedict
ncb3ka@virginia.edu
University of Virginia, United States of America

"A book is not an isolated being: it is a relationship, an axis of innumerable relationships." Jorge Luis Borges's words resonate not only with much of my work on book history, but also with my ongoing digital mapping project of the publishing industry in twentieth-century Argentina. The central aim of my current research is a materially informed look into Borges's process of production in the early part of his literary career (1930-1951): who were his primary publishers? What types of editorial jobs did he hold? Which works were independently printed and which did others fund? What can we tell about his development of aesthetics based on analysis of typography and paper choices? By asking these types of questions about Borges's preferences toward the publication of his own works, we also find that he had a very specific taste for the look and feel of *others'* books and, in one of his early works from this period, makes a snide, and extremely revealing, remark about second-hand bookstores as nothing more than "turgid purgatories." In light of the fact that the places in which a book is published, printed, and even purchased are all key characteristics of that specific volume, I am creating a project with Leaflet and Jekyll that allows me to think deeply about the spatial (and temporal) evolution of the process of publication (and, in turn, the circulation of published works) in Jorge Luis Borges's Argentina (1930-1951).

My project has three distinct layers: mapping the industry, grids of contact, and textual materiality. The first layer uses data from books' colophons and publishers' catalogues to pinpoint the locations of Borges's printers, publishing houses, booksellers, and even places of employment throughout the early part of the twentieth century. The second layer draws on biographical information from the individuals involved in the Argentine book industry to highlight their connections and working relationships. The third and final layer consists of a (visual) catalogue of certain physical aspects of the books in question including their covers, any illustrations, samples of typefaces that certain printers utilized, and any colophons or printers' marks. This data also will include a more general descriptive bibliography of all of Borges's works published between 1930 and 1951, as well as works that he edited, prefaced, or translated during this time. In light of the fact that there are virtually no extant publishers' archives from this historical moment in Argentina and, furthermore, that much of the ephemeral print material related to Borges is in private hands, my aim is to provide researchers and any interested parties with an easily accessible reservoir of data for future projects. Moreover, the specific data collection and interfacing used for this project allow for a deeper understanding of Borges's idea of a book as "an axis of innumerable relationships" and, thus, provide insight into the accessibility of materials, scarcity of resources, aesthetic features, and canon formation in Argentina. In a way, I see this project as something that will not only further material studies (related to the book and publishing history) and digital projects in Southern Cone Literature, but also something that will serve a much wider audience.

Embedding Digital Humanities in a Classics Master Programme

Aurélien Berra
aurelien.berra@gmail.com
Université Paris-Ouest Nanterre, France

Introduction

Pedagogy in the Digital Humanities is now leaving its "bracketed" state – a term used by HIRSCH 2012 to emphasise the fact that this dimension was not given the consideration its practical importance deserves. As programmes and courses are created on a larger scale and increasingly drive institutional strategies, also in Europe (see Sahle, 2013 and the DARIAH Digital Humanities Course Registry), it becomes essential to make comparisons and shared reflections possible.

Since 2014 all students of Greek and Latin languages and literatures at the Université Paris-Ouest Nanterre (France) have been enrolling in a Master programme entitled "Humanités classiques et humani-tés numériques." Each semester features a fully fledged course of Digital Humanities: it is therefore an experiment in embedding Digital Humanities into an existing discipline, or rather into the array of disciplines which constitute the field of Classical studies around its philological backbone.

The aim of this poster is to share the approach I take in designing and teaching these courses, and to reflect on what this experience suggests about digital educational models, in Classics and beyond.

The poster will have three components, devoted to situating, describing and comparing the courses.

Context and History

I will set out the conditions in which the curriculum was reformed (which involves both national and local contexts), the specific problems encountered (as the heterogeneous levels and motivations of the students, the relationships with the other courses, the available technical options, or the recent introduction of podcasting and distance learning), as well as the rationale and methods which shape the courses, including its main sources of inspiration in the Digital Humanities community, whether online syllabi or publications like Jockers (2014) and Rockwell and Sinclair (2016).

Overview of the Courses

The courses alternately take the form of more traditional classes and collaborative or personal pro-jects. Across the two years, their contents include theoretical and historical insights, while concentra-ting on hands-on experience: digital literacy elements are gradually integrated as students go from traditional scholarly editing recreated in Markdown and HTML to critical editing in TEI XML (the focus of year 1) and, beyond text and editing, discover computer-assisted analytical and visualisation methods with the *Voyant Tools* software environment and then work in a literate programming framework (For which the canonical reference is Knuth, 1984) implemented in R Markdown (the focus of year 2, see Figure 1).

Type 'q()' to quit R.

> 
```

Figure 1: Text analysis in RStudio

The principles of the courses will be expounded: favouring active participation, learning-by-doing and flipped classroom teaching; insisting on the critical, reflexive dimension of digital procedures; promoting free resources like *TEI by Example* (Van den Branden, Terras, and Vanhoutte) and *The Programming Historian* (Crymble et al), as well as data reuse; developing an open publication culture through the *Classiques et numériques blog* maintained by the students (see Figure 2) or a shared Zotero group library; creating an awareness of the surrounding Digital Humanities communities; fostering actual collaboration, both between the students and with other projects or programmes – to date, with another MA specialised in Web design on an online edition prototype, with the Pelagios Commons project on the annotation of place names and with the Sunoikisis Digital Classics network in its effort to collectively define a core syllabus.

Comparing Models

Finally, drawing on this experience I will address several aspects of the current development of Di-gital Humanities pedagogy: as a separate entreprise or within established disciplines, with or without infrastructural, collegial or cross-departmental support, in various time formats, with different modes of external collaboration, etc. To sketch this broader typology, I will compare this French series of courses with other models, using in particular the data contributed to the aforementioned Digital Humanities Course Registry.

The poster will be in English, but I will naturally interact with the audience of the poster sessions both in English and French.

Campus AAR est un projet qui vise à développer une plate-forme scientifique pour la production, la description et la publication d'archives audiovisuelles numériques pour la recherche, l'enseignement et la culture. Ce projet a rassemblé quatre partenaires : ESCoM-AAR (FMSH) coordinateur, Armadillo, INA, CCSD, il a été financé par l'Agence Nationale de la Recherche (2014-2016)

Campus AAR s'inscrit dans le contexte des *digital humanities*, plus particulièrement dans celui de la constitution et exploitation de patrimoines scientifiques et culturels des sciences humaines et sociales (SHS) sous forme de corpus ou d'archives audiovisuelles en ligne en vue de leur usage dans la recherche, l'enseignement et la communication-valorisation.

Cette approche correspond aux attentes et besoins des principales parties prenantes d'archives de recherche (i.e. enseignants ; chercheurs, étudiants, doctorants, ...) qui souhaitent intervenir *activement* sur un média audiovisuel (une vidéo, une image) pour le *transformer* en une *ressource intellectuelle à proprement parler* qui leur sert dans leurs activités spécifiques d'apprentissage, d'enseignement, de recherche, etc.

En adoptant une approche cognitive et sémiotique des archives audiovisuelles, le projet Campus AAR se propose de développer une plateforme scientifique et technique pour l'archivage, la description et la publication de vidéos scientifiques diffusées en accès ouvert sous forme d'analyses audiovisuelles, de corpus enrichis et de portails web.

L'objectif principal de Campus-AAR est de mettre au point une infrastructure logicielle déployable ainsi qu'un ensemble de ressources sémantiques permettant d'archiver, d'analyser, d'exposer, de publier, de valoriser, de rechercher et de rendre interopérables des ressources audiovisuelles selon des approches scientifiques variées.

Ce projet a rassemblé quatre partenaires : ESCoM-AAR (FMSH) coordinateur, Armadillo, INA, CCSD) il a été financé par l'Agence Nationale de la Recherche (2014-2016)

Méthodologie et Résultats

Les partenaires ont mis au point une méthodologie de R&D, reposant sur un travail d'expérimentation des outils, mené en étroite concertation avec les acteurs impliqués dans les Humanités Numériques.

La réalisation de scénarii d'usage, correspondant à des cas d'application typiques, a permis de développer et d'évaluer l'environnement Campus-AAR.

Des phases de tests, retraçant les principales étapes de travail avec Campus-AAR, ont été effectuées par un panel représentatif de professionnels, correspondant aux profils types des utilisateurs-cibles du projet.

A l'issue de ces phases de développement, le projet Campus-AAR a réalisé :

- La plateforme d'éditorialisation Campus AAR: une solution logicielle "communautaire" pour l'archivage, l'analyse et la publication de ressources AV
- Les sites et portails audiovisuels Campus AAR : le site central, les collections vidéos sur MediHAL et les portails thématiques constitués d'analyses audiovisuelles (AGORA: Patrimoine en SHS, ARC: Diversité culturelle, AHM: Histoire des Mathématiques).

Le projet Campus-AAR s'adresse aux acteurs du monde scientifique, culturel et universitaire (chercheurs, enseignants, archives, laboratoires, musées, etc.) souhaitant travailler sur un média audiovisuel pour le transformer en une ressource intellectuelle adaptée à des contextes d'usage variés. Il prévoit de mettre à disposition des utilisateurs une plateforme communautaire pour l'archivage, l'analyse et la publication de ressources audiovisuelles, réunissant :

- Le portail central : accès aux logiciels, à la documentation, aux collections et portails audiovisuels
- Les Archives MediHAL - Campus AAR : espace d'archivage pérenne et de diffusion des vidéos - *CCSD*
- Le Studio Campus AAR : logiciel d'édition d'ontologies, d'analyse et de publication audiovisuelles - *INA*
- Le CMS Campus AAR : interface de publication des analyses AV et de gestion des portails - *Armadillo*
- Le Centre de Ressources Métalinguistiques Campus AAR: ressources conceptuelles communes : modèles de données, ontologies, thesaurus - *ES-CoM-AAR*
- Le Back Office triplestore Campus AAR : un environnement pour le traitement des données (gestion des utilisateurs, moteur de recherche, etc.)

Big-Data Oriented Text Analysis for the Humanities: Pedagogical Use of the HathiTrust+Bookworm Tool

The HathiTrust Bookworm (HT+Bookworm) is an interactive tool for visualizing content from the HathiTrust Digital Library, which contains almost 15 million volumes of digitized text (Auvil et al. 2015). Our poster describes the application of HT+Bookworm in teaching. Studies show that the complexity of integrating into pedagogical practice text analysis tools operating over large datasets is a significant barrier to their uptake (Green et al. 2016), and that the best solution is to use a pre-populated text analysis tool (Sinclair and Rockwell 2012, Rockwell et al. 2010). HT+Bookworm accomplishes this by facilitating exploration of the "big" textual data of the HathiTrust Digital Library's collection without requiring mastery of complex technology. We recently used HT+Bookworm in class sessions co-taught by two of us as part of literature classes at the University of Michigan, Ann Arbor to undergraduate students who had no prior familiarity with quantitative approaches to text analysis. One of our objectives was to help students discover how the meanings of words can vary — both when word meanings change over time, and when the same word, when borrowed from one discipline or domain and applied to a different discipline or domain (or simply applied independently in two different domains), takes on separate meanings.

Rens Bod argues that it is only when humanistic disciplines are compared on a large scale that patterns across them become visible (Bod 2013). HT+Bookworm enables the discovery of such patterns by facilitating comparison across categories of knowledge. While search engines are adept at finding individual texts within a digital library, Bookworm performs a different task — abstracting across categories within the library and visualizing those abstractions. These abstractions, which are a form of 'distant reading' (Moretti 2013), are generated in the context of a specific textual fragment (for example, a word or phrase), through the variation of some attribute of the manifestation of that text fragment across the categories defined by some categorization scheme. A typical categorization scheme is the organization of the digital library by Library of Congress (LoC) classes as metadata, and a typical attribute of the manifestation of a word or phrase across categories is its normalized frequency of occurrence across those categories. HT+Bookworm works with both discrete sets of categories such as LoC classes as well as with continuous categories such as time. A time-series plot of the normalized frequency of occurrence of a word over a chronological range, within certain specified LoC classes, provides a sense of how the relative occurrence of that word or phrase has varied across those LoC classes over the specified time range. Students generate visualizations consisting of layered time-series plots (stacked area charts) for the relative frequency of their words of interest, within determinate categories of interest in the HathiTrust Digital Library collection. These categories correspond to the layers (stacks) of the plot, with each layer encompassing an LoC class and time represented along the x-axis. The HT+Bookworm tool also provides, at each point in the plot, a subset list of volumes that contribute the most to the attribute being plotted. This list, accessible by mouse-click at the requisite point, serves as the gateway to the digitized text of the individual volumes in the list. This affordance helps students bridge the gap between the abstraction of distant reading and the discovery of specific texts that they can then investigate further through close reading.

Our poster includes instances of the kinds of exploration HT+Bookworm made possible for students. An example follows. The concept of "fidelity" (an important word to explore in connection with translation studies, a topic of the classes) shows different characteristics when explored in English (in which the concept maps onto the two words "fidelity" and "faithfulness") and in Spanish (where the concept maps onto the single word "fidelidad"). Investigating the occurrence of the word by LoC category allows students to explore hypotheses such as whether the greater strength, historically speaking, of religious tradition in the Spanish-speaking world in comparison with the Anglophone world affects the relative prevalence of this word in different domains of use. Another example is a stacked area chart for a word of a kind for which HT+Bookworm helps provide an understanding of the word's differentiated meanings in different use categories (for example, in the case of the word "depression", in the use category of psychology and medicine versus that of economics). HT+Bookworm accomplishes this by abstracting separately across different LoC classes, while aiding in the indication of the points in time at which, for each class, the word entered widespread usage.

Database of Belarusian Literary Periodicals

Ingo Börner
ingo.boerner@univie.ac.at
University of Vienna, Austria

Gun-Britt Kohler
gun.b.kohler@uni-oldenburg.de
University of Oldenburg, Germany

Sünna Looschen
s.looschen@uni-oldenburg.de
University of Oldenburg, Germany

Introduction

This paper presents the prototype of a "Database of Belarusian Literary Periodicals" developed at the University of Oldenburg, Germany. The project addresses the hitherto under-researched area of Belarusian literature from a field theoretical perspective (Bourdieu, 2002) in combination with a quantitative approach to Literary History (Moretti, 2005).

Belarusian Literature

The case of Belarusian literature is interesting in particular because it constitutes a highly unstable literary field. Due to historical reasons the formation of the literary field and the rise of a literary market dates back only to the beginning of the 20th century. During the first half of the 1920s the establishment of proletarian society in Soviet Belarus entailed the promotion of Belarusian language and literature, which were then consolidated by specific institutions. But already from the second half of the 1920s, cultural politics changed and literary life came under increasing ideological control ending in the infamous 'cleansings' ("čistki") of the 1930s.

Literary Periodicals

Research on the formation of literary markets and fields has illustrated the crucial role of literary periodicals (Bourdieu, 2002; van Rees, 2012). We consider these magazines media that allows us to reconstruct and to analyze the specific structure and internal development of the Belarusian literary field. They allow us to trace the configurations of authors within groups and magazines, the trajectories of single authors and/or literary groups in the field, the differentiation of the literary genre system, the formation of literary criticism and so forth.

The Database

The prototype of the database includes the four most important Belarusian literary periodicals published between 1922 and 1939: *Maladnjak*, *Polymja*, *Uzvišša* and *Kalos'se* (cf. Kohler, 2016). For the time being, we focus on capturing these periodicals' tables of contents, assuming that a systematic analysis of literary periodicals does not necessarily require the literary texts themselves but that the corresponding 'paratexts' suffice (cf. Genette, 1989).

The database currently comprises the tables of contents of 252 issues that were transcribed manually and were encoded according to the TEI-Guidelines. The database itself is set up as an application for the open-source XML database eXistdb. An extensive range of search queries can be performed on the corpus, which enables users to identify quantitative characteristics of the periodicals and its contributing authors. It allows for the export of the data as a dynamic network graph in the gefx-format (Gephi).

Pilot study: corpus, questions, and method

For the pilot study we specifically focus a) on the period 1922–1932 (the year 1932 marks the end of literary diversity: groups and magazines dissolved and fused into the 'one' Writers' Association with its official periodical *Polymja*), and b) on the three periodicals in Soviet Belarus (*Kalos'se* was established only in 1934 and was published in the Polish part of the country). Taking into account this focus, the pilot study deals with a complete corpus of 189 issues.

We focused on the analysis of c) authors' trajectories (fluctuations between periodicals), including the question of "splinter groups' trajectories" and of d) hierarchization of authors. These questions are interlinked with the questions, e) whether an author's movement from one periodical to another brings an increase of his/her publication frequency, and how the constellation of authors changed in relation to such movements.

Step 1: Identification of authors: Problems we had to overcome in this respect were variations in spelling and the frequent use of acronyms and pseudonyms. The use of pseudonyms is in some cases not only linked to the periodical (some authors published in one magazine using their real name and under pseudonyms in the others) but also to the author's role (e.g. writer vs. critic/reviewer).

Step 2: Identified authors were linked to a <person> record, where additional information on each identified author is stored. If available, these entries were linked to authority files (VIAF). As the coverage of Belarusian authors in the relevant authority files is rather incomplete, the authors were also linked to the corresponding Wikidata entries, to provide for an external unique identifier.

Step 3 (question 'd'): We identified frequently published authors and compared their rankings in the periodicals at several points in time but also focused on literary reviews and translations.

Step 4 (questions ‘c’, ‘e’, ‘f’): We observed a relatively high fluctuation of authors and splinter groups between the periodicals, including also the authors that published most frequently. In analyzing the movements of authors, it was possible to complement hitherto lacking insights and background knowledge about the journals’ interconnectedness.

DH Uncentered: Fostering Partnerships Within a Digital Humanities Network

Laura Braunstein
lrb@dartmouth.edu
Dartmouth College, United States of America

Scott S. Millspaugh
scott.s.millspaugh@dartmouth.edu
Dartmouth College, United States of America

During the academic year 2014-15, Dartmouth College launched an informal Digital Humanities initiative. Individual researchers and campus stakeholders already constituted a loose digital humanities network at the college, and had for years, but these projects had not been coordinated through any kind of centralized infrastructure. In spring 2015, Laura Braunstein (Digital Humanities Librarian) and Scott Millspaugh (Instructional Designer), proposed to pilot a faculty residency program during the summer term. Funded by the Dartmouth College Library and Information Technology Services (ITS), the residency program had the following objectives:

- to prototype a team-based approach to supporting digital humanities projects that could be standardized for future implementation; and
- to test the capacity of the Library and ITS to support digital humanities projects without recourse to external sources of funding.

The project selected for the Residency Program Pilot was *Multimedia in the Long Eighteenth Century* (MMLEC), led by faculty PI Scott Sanders (Assistant Professor of French). The MMLEC project seeks to quantify the frequency with which musical paratext, including both lyrics and musical notation, appear in English- and French-language novels published between 1688 and 1815. Professor Sanders, John Wallace (Research Systems Engineer), and Jill Baron (Romance Languages Librarian) had been collaborating on the project since late 2014, and Sanders and Wallace had already presented a plan for the project at the Digital Libraries for Musicology Workshop 2015. The Residency Program Pilot allowed for the expansion of the core project team and funded the employment of two student workers who created a trained data set under the direction of Mark Boettcher (Senior Programmer and Analyst). The Pilot also led to the involvement of the Digital Library Technologies Group (DLTG), which has assisted in the creation of a bibliographic database, still in development, of published French-language works from the eighteenth-century.

The Residency Program Pilot was successful in establishing a model for institutional support of other DH projects in the pipeline at Dartmouth and has allowed the Library and ITS to develop a process for evaluating and prioritizing those projects. In the summer of 2016, we renewed the Residency Program for another year with the Jamaican Slave Names Project (JSNP). Our poster will narrativize the development of MMLEC and JSNP within the context of the Residency Program and demonstrate how institutional support of a digital humanities project can help foster community and cross-campus collaboration in the absence of a dedicated DH program or center. We hope to dialogue with colleagues at other international institutions present at DH2017 that have established different models of support for digital projects in the arts and humanities and to offer guidance to those that are initiating cross-campus collaborations within a network of individual researchers, centers, and administrative groups, instead of concentrating digital humanities support within a single program or center.

Research data play a fundamental role in science and the arts and humanities, a large part of them being either digitised or of digital provenance nowadays. Digital research data are fragile, which means that their thorough management and preservation is crucial to prevent the loss of data and information, avoid redundant data collection, enable more efficient research, ensure the verifiability and reproducibility of research results as well as the citability and reusability of research data.

The management and long-term preservation of digital research data requires an infrastructure that takes into account the digital nature and heterogeneity of the data and the diverse requirements of the research community. Research data centres, such as the Humanities Data Centre (HDC), are key players in this context. They provide a safe and trustworthy place for researchers to deposit their data as well as to search for and get access to previously deposited data. They also act as centres of expertise, offering training and support to their community. The importance of case-specific consultation must not be underestimated as the heterogeneity of digital research data and the wide range of data management tasks across the data life cycle call for extensive support by data experts.

Comprising of a large number of disciplines and employing a variety of different research methods, the arts and humanities produce very heterogeneous research data. A great deal of them are file-based data, such as text, audio or video files. But there is an increasing number of more complex research data, such as digital editions or visualisation frameworks, that consist of various interwoven layers of different types of data. In these instances, it is often hard or impossible to distinguish between the "primary data" and the software application that is used to process and display the data. While there are more or less established solutions for file-based data (e.g. repositories), the curation and long-term preservation of complex data types still poses a challenge to infrastructure providers.

In view of this background, the HDC developed an initial service portfolio in its design phase that responds to the heterogeneity and complexity of arts and humanities research data by offering consultation and training, repository services for file-based data and the application preservation. The latter is designed to sustain representations of complex research data such as digital editions or visualisation frameworks.

What are the challenges for the research data centre in this? Continuous access to static systems in a developing environment will create problems sooner or later - the systems will eventually become outdated and inaccessible. On the technological level, there are basically two concepts to preserve applications: either virtualisation or emulation of components. While emulation allows the operation of software (such as an operating system) on hardware and software environments it had not been developed for, it costs extra computing power to emulate the required environment, to name only one disadvantage. Virtualisation comes with the clear benefit that the hardware appears as a physical device to the system and to the software modules. The disadvantage is that the virtualised environment must be sufficiently performant directly on the hardware. But for most of the use cases considered here, only standard hardware is being used. Hence the advantage of running more than one virtualised system and the relatively simple management of these systems makes the virtualisation the state of the art approach. The poster illustrates how the application preservation of the HDC uses virtualisation to preserve complex research data applications in a protected environment and ensure their representation, citation and use for a finite period of time.

Mapping Linked Data Subject Headings in the Library Catalog

The MARC-based library catalog is text-based: in order to find relevant information, a researcher must use text to identify an author, title, or subject. Our team has been expanding the paradigm of text-based discovery by exploring visual discovery, building a browsable map of our library catalog based on record authority and linked open data. This geospatial representation of our holdings not only offers researchers a new mode of discovery; it also opens the door for new avenues of research by highlighting unexpected connections and virtually collocating materials that are classified and shelved separately. The process is as follows. 1. Newly catalogued items are assigned a stable URI from Pleiades, the open-access ancient world gazetteer (Bagnall et al., 2016), reflecting our Institute's scholarly focus and library holdings. 2. This identifier is added as a subject heading in the item's MARC record. 3. This data is exported, cross-referenced with geoJSON records containing latitude and longitude data (Baumann, 2014), and mapped using Leaflet.js (Agafonkin, 2016). The mapped representation of the catalog serves as an alternative mode of discovery for researchers, who can now browse for library materials by focusing on, for example, a general region of the Near East, a city in ancient Egypt, or a specific archaeological site in China. The experimental nature of this map-based discovery has become all the more viable as the Library of Congress has recently added Pleiades to its list of subject heading authorities. (Library of Congress, 2016) So, while the inclusion of linked data in MARC records has seen some adoption in recent years (Papadakis et al., 2015), this imprimatur from the LOC for Pleiades opens up massive potential for geographical linked data specifically. Other projects have mapped LOC subject headings (e.g. Freeland et al., 2008; Bennett et al., 2011), but this is the first project to do so directly from linked data embedded in MARC records. Accordingly, this project heeds the recent call of the MIT Future of Libraries report (MIT Libraries, 2016) to provide "comprehensive, accessible, digital content" in library discovery that supports the ability to "combine, manipulate, [and] visualize" library data for the global community. Our poster includes: an explanation of the linked-data principles underlying the project, our visualization workflow, and an example of mapped catalog data from books acquired in the fourth quarter of 2016, presented both as a static map on the poster as well as a live, browsable demo on a tablet.

A New and Improved Method to Text-Mining in Chinese: Closer Language Segmentation in Detecting the Shifting Meaning of Patriotism

Annie S. Chao
mrsannechao@gmail.com
Rice University, United States of America

Qiwei Li
liqiwei2000@gmail.com
Rice University, United States of America

We aim to demonstrate a new methodology for detecting shifting nuances of ideas in Chinese intellectual history. Our subject is Chen Duxiu (1879-1942), founder of the Chinese Communist Party (CCP) and one of the most important historical figures of twentieth century China. We combine the latest text-mining tools with statistical analysis and natural language law, based on word frequency calculations. Because the Chinese language does not have spaces between words, and because each word is comprised of either a single or multiple characters or morphemes, segmentation of Chinese text poses a set of different challenges than for English corpus. By using a Chinese tokenization plug-in for R called JiebaR, we have developed a more precise method to create a Chinese natural language curve that conforms closely to Zipf's law, a commonly used model for distribution of words in a corpus. Zipf's law states that given a body of natural language text, the frequency of any word is inversely proportional to its rank. (Ha et al., 2003) For Chinese language, Zipf's law applies for words made up of multiple morphemes. (Xiao, 2008)

Our assumption is that a word is significant when its position on our curve deviates from the fitted curve based on Zipf's law. Departing from an existing method developed by Prof. Jin's team, we created two groups of keywords, and called them "anchor" and "companion" words. (Jin et al., 2014) "Anchor" words have large residuals (high deviation from the standard curve), and "companion" words have a high correlation with "anchor" words. We used the formula for Pearson's correlation coefficient to find the companion words. The coefficient has a value of between +1 and -1. The companion words provide the context with which to interpret the anchor words. Unlike Prof. Jin's team, we included keywords made up of more than two characters, such as the three character word for Nationalist party, Guomindang (國民黨), the four character word for citizen's assembly, guomin huiyi(國民會議), and the five character word for Marxism, makesizhuyi (馬克思主義).

The goal of our research is to analyze changing meaning of the concept of patriotism in Chen's writing from the beginning of his publishing career, ca. 1897, to the end of his life, 1942. Why is Chen such a fascinating figure to study? In addition to creating a political party that changed the course of Chinese history, Chen was equally, if not more, influential in bringing about the first cultural revolution of twentieth century China. Living at a time of great political unrest, Chen wrote passionately on the need to reform the people by revolutionizing Chinese culture, thoughts, and politics. After founding the CCP in 1920-21, Chen was expelled from the party in 1929 due to ideological differences. He was subsequently jailed by Chiang Kai-shek's Nationalist Party, and died a political pariah a few years later. As his political and personal fortune waxed and waned, Chen's conception of patriotism shifted. For this paper, we chose six important anchor words: citizen (國民), youth (青年), democracy (民主), revolution (革命), people (民族) and being patriotic (愛國). Our method is replicable for other corpus, with the understanding that the conclusion is derived with the additional layer of human deliberation.

New literacy is not to be taken as merely a change in how we understand and present information because of newly-developed technologies, but as a way of transforming how we interact with texts and with the world as a whole. This study aims to report an empirical study on how four types of digital natives, all born in the 1980s, access information and create content. Data was collected through one-on-one semi-structured interviews with 28 writers, illustrators, social innovators, and makers in total, seven in each category. The data were then processed as follows: First, we employed qualitative analysis and interpretation through close readings and meaning-making. Second, we quantitatively deconstructed the text by atomizing the discourse with Chinese Knowledge and Information Processing (CKIP) and filtering out units that are irrelevant to the analysis. Finally, we generated comparisons among the four contemporary groups and their new literacy practices.

Writers

In contrast to their counterparts from the older generation who were devoted to a single identity such as being a novelist, columnist, or essayist, young creative writers who have won literature awards and published top-ranking books grew up within a social environment of PTT, blogs, and Facebook. They are accustomed to managing their primary literate role while at the same time enjoying multitasking by being active across new media platforms and acting as popular commentators for social issues related to their academic training such as education, sociology, gender study, and philosophy. They obtain a vast quantity of high quality information from their social media stratosphere and they share opinions and ideas through social media services with their followers as a form of self-presentation, or “performance” in Goffman’s term.

Illustrators

The internet and social media have brought changes to people’s reading habits in many ways; for example, “Picture Reading” and illustrated creative blogs have become very popular in Taiwan over the last decade. Therefore, illustrators who devote effort to character creation and social media fan page management are increasing in number. They obtain inspiration from daily life and can transform their observations into creative content. These illustrators integrate their interests and capacities to share their artwork on the Internet, and they attempt to develop a business model that involves a multivariate form of production.

Social innovators

Social innovators attempt to employ strategies and actions to solve community or city problems through teamwork with the goal of making the world a better place. They use technology as a means of connecting resources in the process. Their goal is to penetrate social problems and issues, identify the needs of communities they target, develop innovative solutions, and take action. One of their primary strategies for achieving this goal is to collaborate with local people to create stories for the public, who thus can understand the value and meaning behind these stories. Their storytelling is multimodal in nature to accommodate the needs of the general public.

Makers

The “maker movement” has emerged in Taiwan over the last several years, and under the social environment of learning by doing, makers create a small amount of delicate products and are very open regarding sharing their ideas and creative processes. They suggest that traditional education in Taiwan neglects the significance of DIY and are enthusiastic about the culture of makers, who emphasize learning, doing, and sharing. They are very persistent about their own interests, and empower themselves with knowledge and skills through self-directed learning, pursuing an ideal living style and working arrangement.

Insight from word clouds and the co–occurrence of key words

The word clouds of writers illuminate a central focus is on words, articles and literature. The literacy practice of these writers is to express feelings and provide arguments about issues. By contrast, illustrators are interest-driven; they enjoy sharing life stories and ideas with their friends, and are followed by social media fans who adore the characters they have created. The central focus of social innovators is on society, community, and local issues and needs; and their resources and contributions include teamwork, space, activities, cultural artifacts, and communication between people and the government. Finally, makers are interest-driven and they enjoy sharing life experiences through their creations and products like illustrators. Much like social innovators, makers access information and create content in both the cyber world and in the physical world.

La localisation du jaune dans des dessins de dieux réalisés par des enfants

Sabine Süsstrunk
sabine.susstrunk@epfl.ch
University of Lausanne, Switzerland

Dans le cadre de la recherche interdisciplinaire, “Drawings of gods” (financé par le Fonds National Suisse), ancrée en psychologie de la religion et visant à comprendre les stratégies cognitives mises en œuvre par les enfants pour dessiner “dieu” (Brandt et al., 2009, Dandarova, 2013, Brandt, 2016), une question s’est posée quant à l’utilisation du jaune : “Est-ce que le jaune est une couleur privilégiée dans la représentation de dieux parce que la lumière est souvent associée au divin et que le jaune est utilisé pour représenter la lumière ?”.

Afin de répondre à cette question, une première annotation manuelle des dessins collectés par les chercheurs dans différents pays a été effectuée dans une feuille de calcul, spécifiant dans quelle zone de l'image se trouve le jaune (au milieu, autour de la figure principale de dieu, en périphérie), s'il y avait présence d'un soleil jaune ou pas de jaune.

Ce projet comptant actuellement plus de 6'500 dessins, il est devenu nécessaire de faire appel à une annotation automatique. Aussi, il est intéressant, du point de vue de la psychologie, de comprendre quelles décisions humaines peuvent être reproduites par un ordinateur. Bien que les méthodes de traitement d'images et de vision par ordinateur, combinées aux algorithmes de classification supervisée, soient très développées et performantes pour le traitement d'images naturelles (Szeliski, 2010), elles le sont beaucoup moins pour le traitement de dessins (Stork, 2009). Par conséquent, ce travail consiste à explorer les techniques possibles et à trouver des caractéristiques ("features") pertinentes pour une classification supervisée.

Pratiquement, après avoir défini ce qu'était la couleur jaune dans les dessins et extrait cette dernière, toutes les images ont été transformées en format carré, afin de permettre la comparaison des dessins au format paysage et au format portrait. Ensuite, différentes approches ont été testées pour reproduire l'annotation manuelle. La première consistait à extraire la gravité du jaune, définie comme la moyenne de l'intensité de cette couleur par ligne (respectivement par colonne), pour la hauteur (respectivement la largeur) de chaque dessin. Comme attendu, les courbes obtenues montrent des pics dans les zones contenant une forte concentration de jaune, clairement repérables à l'œil nu. Cependant, en raison de la variabilité de l'intensité du jaune entre les différents dessins et l'application non régulière des couleurs dans chaque dessin, il n'a pas pu être défini de critère permettant de repérer ces pics.

Dans un second temps, partant de la première approche, le centre de gravité du jaune dans chaque dessin a été extrait et deux cercles ayant pour origine ce centre ont été définis. Le but alors visé était de définir des surfaces correspondant aux zones annotées manuellement (milieu, autour ou périphérie), en se basant sur une hypothèse forte estimant que le centre de gravité du jaune correspond à celui de la figure principale. Cette méthode, qui a conduit à analyser les intensités de jaune dans les secteurs circulaires des cercles, a à nouveau été mise à mal par la variabilité dans l'ensemble des dessins.

Inspirée de l'idée de zones délimitant l'espace de la seconde approche, la dernière méthode a consisté à diviser l'image carrée en 25 cases, formant ainsi une grille de cinq par cinq. Ensuite, en fonction de l'intensité du jaune dans chacune de ces cases et en faisant l'hypothèse que la figure principale est au centre de l'image, comme souvent observé dans les dessins d'enfants (Golomb, 1987, Winner, 2006), une série de conditions ont été choisies afin de déterminer la zone dans laquelle se trouve le jaune. En raison des résultats prometteurs ainsi obtenus, une classification supervisée multi-étiquette a été effectuée, utilisant, pour chaque image, les 25 cases comme caractéristiques des données et les annotations manuelles ("ground trouth") comme étiquettes. Les meilleurs résultats ont été obtenus avec la méthode des "plus proches voisins". À nouveau, la grande variété des techniques de dessins utilisées par les enfants, tout comme la non-constance de la position de la figure principale, conduisent à plusieurs erreurs.

Ce travail, en cours, explore actuellement de nouvelles pistes, telles que la prise en compte d'autres couleurs, la modification des paramètres de l'algorithme de classification supervisée, la définition d'une nouvelle grille permettant de prendre en compte la position de la figure principale, etc. Pour conclure, il est clair que les données sous forme de dessins, souvent utilisées en psychologie, méritent une exploration systématique des méthodes permettant de les exploiter numériquement, ceci afin de pouvoir les traiter efficacement en quantité.

Digital Humanities Clinics – Leading Dutch Librarians into DH

Michiel Cock
m.p.cock@vu.nl
Vrije Universiteit Amsterdam, the Netherlands

Lotte Wilms
lotte.wilms@kb.nl
National Library of the Netherlands, the Netherlands

In 2015, an initiative was started to set up a Dutch speaking DH+Lib community in the Netherlands and Belgium, based on the example of the American communal space of librarians, archivists, LIS graduate students, and information specialists to discuss topics ‘Where the Digital Humanities and Libraries meet’. At the initial meeting it became apparent that most participants were there to learn more about digital humanities and were not (yet) in the situation where they were able to offer expertise on the subject. On the administrative level, the directors of the libraries participating in the consortium of Dutch academic libraries (UKB) also expressed the wish that librarians become more fluent in DH.

A year later, the National Library of the Netherlands (Koninklijke Bibliotheek), and the University Library of the Vrije Universiteit Amsterdam again concluded that librarians at their institutes who wanted to get involved in DH needed more training to adequately support researchers and students in this field. Therefore both institutes joined forces to develop a set of clinics on DH for librarians. The two institutes were later joined by the Leiden University Libraries. We see this as the ideal opportunity to provide these educative sessions not only to our own librarians, but also to the academic librarians of other Dutch research libraries. In essence, we want to teach our country’s librarians the ins and outs of DH in order for them to take up their natural role of facilitating and supporting research and ideally become the research partner needed in DH projects.

The aim of these clinics is to provide basic methodological competencies and technical skills in DH, for a diverse group of librarians, consisting of both subject and technical librarians with basic technical skills. The content of these sessions should enable them to provide services to researchers and students, identify remaining gaps in knowledge or skills that they could address by self-directed learning and (perhaps) to automate their daily library work. We are not setting out to turn them into programmers or data crunchers, but want to boost their knowledge level to where they feel comfortable providing information about DH projects, follow the literature and research, follow online tutorials and hopefully take up the challenge of finishing this professional development by engaging with the DH community.

In order to design this curriculum we follow a four step approach with a Working Out Loud-principle (Williams, 2010):

1. Desk research about what being a DH librarian entails (e.g. Hartsell-Gundy et al., 2015; Mulligan, 2016; also see the Zotero library of the LIBER Digital Humanities working group);
2. Identify possible subjects, based on experience, a comparison of existing teaching material related to DH (e.g. The Programming Historian, the Digital Scholarship Training Programme at the British Library and Columbia University's Developing Librarian project) and the TaDiRAH taxonomy of research activities;
3. Get feedback from researchers on possible subjects, based on the knowledge and skills they feel librarians need;
4. Get feedback from librarians on possible subjects, based on already known gaps in their knowledge and skills.

With these in hand, we will design the curriculum of clinics, based on the method of 'constructive alignment' (Biggs et al., 2011), to make sure that the intended learning objectives and the teaching/learning activities stay aligned.

Our plan is to organize a maximum of 6 clinics, each one full day. Each day starts with one or more lectures by researchers, that address the conceptual knowledge needed. The afternoon sessions will be devoted to the hands-on training of skills, following the Library Carpentry model as closely as possible. By having researchers provide the lecture sessions, we hope to fuel the enthusiasm of the librarians with the inspiration of direct contact with researchers and to provide access to a network within and across universities. With these clinics, we hope to initiate a stream of DH activities in Dutch universities, making access to support easier for new digital scholars.

The poster at DH2017 will present the curriculum, its position in the international context and offer the lessons learned from both the design process and the first clinics. We welcome discussion about our efforts and the possibilities of applying this in other contexts.

Your Own Personal Matrix: Generationally Mediated Realities and Digital Cultures of Choice

Adrian L. Cook
adrian.cook@tccd.edu
Tarrant Country College, United States of America

The 1999 film may have been prophetic. The Matrix has us. But our children may have the Matrix. . .under their control. And it can be personalized.

This project, now at its seed level, merges performance studies, critical media studies and a reading of Jean Baudrillard's idea of simulations and simulacrum to examine the dramatization of our social reality as it occurs through each evolution of broadcast media in the twentieth century. Since the emergence of broadcast radio, each American generation has interpreted and aesthetically crafted a consensus reality that, with the onset of cable TV and the internet, has become somewhat of a simulation. This project claims that Generation Z (born after 2001) will inherit a social reality that is so highly filtered and aesthetically shaped as to be more of an abstraction of objective truth than narrative drama or even video games. Furthermore, the additional mediation of algorithms designed initially for marketing purposes will provide for Generation Z "realities of choice."

This investigation began as I observed my young daughter asserting her perceived right to choose her digitally delivered entertainment from a seemingly endless menu. The Gen Xers (my generation) are in charge of producing these entertainments, while Millennials form the bulk of the writers. This is strange alchemy, as Gen X produces both documentary and narrative drama that critiques the mythical post-war reality created by Baby Boomers, Millennials internalize and interpret that critique, producing infinite variations on themes by virtue of the sheer number of digital outlets and accessible, user friendly storytelling tools. The conceptual model of generational mediation to be presented, shows the gradual movement away from a relatively objective (or let us say homogenized consensus) social reality to and a multi-cyber-verse of highly mediated realities. The irony is that, while the beauty of this techno-narrative state allows an exponentially diversifying population space and accessibility for disseminating their narrative and to communicate their cultural reality; the option to personalize our input, in tandem with our twenty-first century culture of convenience, means that we may never see and experience nor empathize with the lives of "Others."

This work marks a continuation of a dissertation on performing myth in virtual realities and the foundational level of a "Generational Reality Theory," an examination of meaning making, knowledge acquisition and generational ways of being as codified cultural expressions. In other words, because of our emerging ability to perform ourselves and shape our perception of reality wholesale via media spaces, and the likely development of digital (and other virtual) platforms beyond our current imagination, each subsequent generation is living, quite literally, in a different reality to the extent that cross-generational communication – and for professors, andragogy – is equivalent to cross-cultural communication.

This poster presentation will introduce our Active Archives Initiative, through which we aim to develop new, dynamic ways of representing, researching, and learning about the past through digital archives. From a traditional library studies perspective, most online archives are mere digital repositories, lacking the institutional and hierarchical nature of a traditional archive. Driven by a growing number of available online resources, digital technologies and tools that foster social interaction and collaboration, and open metadata, web standards and APIs, the notion of an archive continues to shift and expand.

Yet rethinking the definition of an archive is not merely a result of the digitization of existing cultural knowledge or the advent of born-digital repositories. Walter Benjamin, for example, thought of his Arcades Project — a dynamically re-organizable archive of quotes, sources, and references, developed long before the advent of modern digital technology — as something that could not leverage its full potential by being bound into a book. More recently, Wolfgang Ernst in *Digital Memory and the Archive* (2013, 81) challenges the notion of a closed archive by pointing to the fact that "new archives are successively generated according to current needs ... the object-oriented archive thus takes shape cumulatively, entailing a shift from read-only paradigms to a generative, participative form of archival reading." Laermans and Gielen (2007), moreover, observe " a quasi-bifurcation in the ways the digital archive is observed and evaluated by traditional archivists and other archive specialists", relating to the "differences between old and new media." As these examples serve to show, not merely archives in practice, but the *idea* of an archive in theory, is constantly being redefined depending on shifting needs, audiences, and available content.

Ernst's notion of a generative, participative mode of archival reading is central to the approach we introduce here. The core purpose of our Active Archives initiative is to empower users to engage in 'story-making', by discovering, interpreting and re-organizing archived materials to construct new representations of the past. In some cases, indeed, users might have their own material to contribute, which we intend to also enable. This we propose drawing together data and documents from multiple sources to enable multiple groups of users to reassemble these materials, and in so doing, challenge existing narratives and reimagine others. In many cases, the materials being used are only available in photocopy quality at best: the archive we envisage therefore allows the opportunity for the reinterpretation of valuable but incomplete resources. Our goal is to make these archives easy to understand and enjoyable to use, and to design them with a wide range of prospective users in mind, from professional scholars to high school students.

We have selected two existing projects as prototypes for this initiative. The US-Iran Relations project, a collaboration with MIT's Center for International Studies and the partners in the US and abroad, collects and digitizes governmental documents and testimonies by policymakers relating to the diplomatic relationship between the United States and Iran during the past several decades. Our second project, the Blacks in American Medicine archive, combines tens of thousands of biographical records of African American physicians with countless primary documents associated with these practitioners to create a comprehensive archive of all black physicians within the United States from 1860 to 1980. These projects leverage interactive tools such as dynamic timelines combined with customizable faceted browsers and innovative collection and story-making tools, allowing previously untold narratives and unseen connections to emerge. This will enable, as Ernst describes, "the digital archive shift to regeneration, (co-)produced by online users for their own needs" (2013, 95) while simultaneously becoming a source of dynamic media memory.

As the nature of digital scholarship changes, we need to enable archives to change as well. As we continue to develop our Active Archives Initiative, we're putting particular emphasis on the idea that our archival content is not only accessible but, more importantly, that it is intuitive and useful to diverse audiences. To that end, we hope to create fully realized, open and collaborative spaces that foster not only the proliferation of untold stories but also the ability to interact with these slices of the past in new and innovative ways. Presenting our work at DH2017 will also allow us to gather useful feedback from other practitioners in the field of Digital Humanities looking to similarly shake up the staid notion of an archive. As such, our poster presentation will offer both technical details, such as screenshots of the prototype in action, as well as clear description of the functionality and responses to our user testing.

DHConnections: Examining the Growth of the Digital Humanities Summer Institute Community

Cole Crawford
cole.crawford@oregonstate.edu
Oregon State University

The Digital Humanities Summer Institute, or DHSI, provides "an ideal environment for discussing and learning about new computing technologies and how they are influencing teaching, research, dissemination, creation, and preservation in different disciplines, via a community-based approach" (DHSI). What began in 2001 as a small event at Malaspina University-College is now an annual 2-week affair at the University of Victoria which offers dozens of sessions and attracts a global audience. The growth of DHSI over the past 16 years mirrors the larger development of digital humanities as an academic (inter)discipline that has shifted from a niche endeavor for computational linguists and technology early-adopters to both a mainstream methodological approach and a distributed community of practitioners.

DHConnections examines DHSI attendance data. This website functions both as a tool for research about DHSI (and thus the history of disciplinary training in the digital humanities), and as a platform for DHSI alumni to connect with other researchers with similar interests, or to reconnect with contacts from previous DHSI sessions. In this way, *DHConnections* intersects with the "Collaborators" component of centerNet's excellent *DH Commons* website, but is more explicitly focused on the distributed community of DHSI alumni.

The DHSI organizational team maintains an archive of past DHSI sessions and participants. With the permission of DHSI and the Electronic Textual Cultures Laboratory at University of Victoria, I scraped this collection and cleaned it with OpenRefine to remove typographical errors, standardize attendee and organization names, and validate the data. There is no participant data (only instructors) for 2001-2003, but since 2004 there is an accurate list matching every attendee to the session he or she attended. This information is further broken out by role – student, instructor, speaker, or staff, with numerous specific subcategories of each. From 2006 onward, attendee institutional and organizational affiliations are also included. I also built a controlled vocabulary of DH topics and manually added topics to each session based on the session title and abstract when available. Together, these components form a temporal, topical, spatial, and biographical dataset which captures the attendance data for 2,678 individuals who collectively attended 254 sessions across 4,932 instances.

DHConnections allows users to access and interpret this dataset. Researchers can access the raw data via a JSON endpoint, but *DHConnections* also features numerous interactive interfaces which provide intuitive ways to understand the growth of DHSI through what Joanna Drucker calls "visual epistemologies … ways of knowing that are presented and processed visually" (2014, 8). These include a searchable table of all participants; charts of the growth of DHSI over time by country, and by total institutional attendance; a facetable map of participants' institutional affiliations; a graph which examines the popularity of DHSI session topics and when they were introduced (figure 1); and a searchable network graph of participants, linked by session attendance, scaled by frequency, and color-coded by participant role. These and other visualizations provide information about the growth of an international DH and DHSI constituency, identify major contributors and organizations within the field, and assist DH researchers interested in finding contacts.

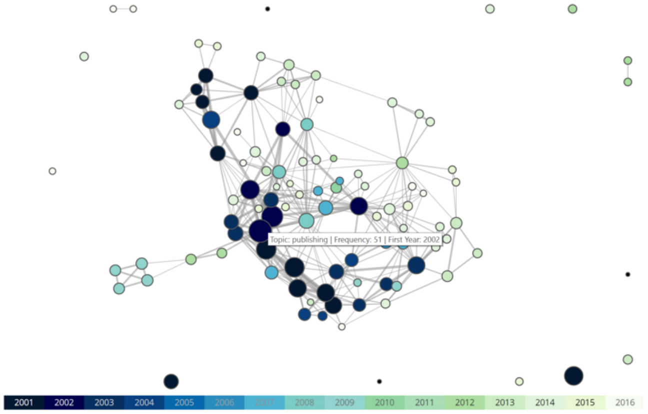

Figure 1: Topics assigned to DHSI sessions, colored by year introduced and sized by frequency

DHConnections also helps users connect with fellow DHSI alumni and find potential collaborators. For example, users interested in organizing a maker fair could query the database for DHSI alumni within 200 miles who attended a session between 2010 and 2016 and are interested in the topics of "3D printing," "augmented / virtual reality," "physical computing," or "maker culture and praxis." While "interests" are currently established by proxy via a link to attended session topics, the accuracy of such a search will increase over time because users can claim their profile on the site via an opt-in process.

Once a user claims his or her profile, he or she can edit their institutional affiliations; research interests; projects, papers, or personal websites; and/or contact information (Twitter / email). Users are also able to quickly opt-out of *DHConnections* and anonymize their attendance. *DHConnections* is designed for eventual expansion based on the availability of additional data sources such as lists of members or participants in THATCamps, HASTAC, HILT, European Summer University, DH@Madrid, DHOxSS, and conferences such as ADHO.

This poster presentation will allow ADHO attendees to test *DHConnections*. As the creator and developer of the project, I will be able to answer any questions about *DHConnections* and the underlying dataset, and look forward to talking to users and gathering feedback to help improve the platform.

Beyond the Historic Facade: Skyscrapers, Scapegoats, and the Digital Reclamation of Toronto's Queer Streetscapes

Constance Crompton
constance.crompton@ubc.ca
University of British Columbia, Canada

Michelle Schwartz
michelle.schwartz@ryerson.ca
Ryerson University, Canada

Gentrification takes many forms, ranging from whole scale bulldozing and forced relocations, to skyrocketing rents and dominion of multinational corporations over entire neighbourhoods. In Toronto, gentrification is facadist: the hollowed brick skins of Victorian storefronts are preserved in orderly rows, with great glass office buildings or condos sprouting up through their once-solid roofs and porticos. Luxury boutiques and art galleries take over the spaces once held by convenience stores and leave the original, rusting signage above the door, urging pedestrians to drink Coke. A local diner closes one night and reopens the next as a cocktail lounge - the interior and exterior remain untouched. The same 1960s banquets that once served $5 burgers to an impoverished and marginalized local population now serve burgers that cost $17, even though the name advertised on the now-vintage neon sign outside remains the same.

Most city dwellers are familiar with these external signs of gentrification. Gentrification, however, does not just shape the streetscape, it shapes the outlook of city dwellers in a way that obliterates urban history, especially the history of marginalized communities, even though it is these diverse populations of people of colour, immigrants, queers, and the working poor that gave cities the dynamic qualities that made them initially so attractive to new residents. In Toronto, the building boom of the last decade has left only the facade of much of the city's diverse history. What is behind the facade - luxury condos and chain stores - represents a completely different model for a city, one that prioritizes neoliberalism, conservative values, and the homogenization of thought.

In the traditional narrative of gentrification, gentrification begins with the influx of white gay and artistic communities, the so-called "creative class," into economically disadvantaged areas. These "shock troops" of gentrification clear the way for yuppies with their preference for boutique coffee shops and organic vegetables. Rents rise and the original low-income or minority population of the neighbourhood is displaced, pushed further and further to the margins as the initial hot spot of gentrification rapidly expands. According to Sarah Schulman, Distinguished Professor of the Humanities at the College of Staten Island, this traditional narrative does not get to the heart of gentrification. The gay community has become a convenient straw man for an outcome that is shaped by much more powerful forces in municipal government, and the changing tenor of city life is due not to the introduction of artists spaces, but to the "gentrification of the mind" or the suburbanization of our understanding of city space.

In her book, The Gentrification of the Mind, Schulman quotes the artist Penny Arcade's piece "New York Values": "There is a gentrification that happens to buildings and neighborhoods and there is a gentrification that happens to ideas." Gentrification, according to Schulman's theory, is caused not simply by the influx of new people, but when those people come to cities "not to join in or to learn and evolve, but to homogenize," bringing "the values of the gated community and a willingness to trade freedom for security" (30). Gentrification "replaces most people's experiences with the perceptions of the privileged and calls that reality" and as a result "gentrified happiness is often available to us in return for collusion with injustice" (161, 166).

In the remaking of Toronto as a city of facades, are we not only erasing our history, but permanently altering the idea of what our city is, who it is for, and what purpose it serves?

And is there a way the digital humanities scholars in particular can fight these forces to a halt? Drawing on Schulman's argument and using the Lesbian and Gay Liberation in Canada project's spatial model of the Toronto gay scene as a case study, the short paper proposed here will argue that the freely accessible publication of digital models of historical communities can be used to push back against the gentrification of the mind. The presentation that will accompany the paper will mark the launch of the Lesbian and Gay Liberation in Canada map, built from the 17,000+ person, place, and event entity records in the LGLC database.

The Lesbian and Gay Liberation in Canada project reconfigures Donald McLeod’s remarkable two-volume work, Lesbian and Gay Liberation In Canada: A Selected Annotated Chronology, 1964-1981 as a TEI-encoded resource and graph database. The prototype database, available at http://lglc.ca consists of event, publication, person, and place records spanning from the founding of the first homophile associations in Canada through to the start of the AIDS crisis. The LGLC project extends McLeod’s codex form in order to data mine and represent queer history spatially and temporally. The project not only makes a much-neglected part of Canadian history available for mainstream scholarly use, it also provides a foundation for modeling identity and representing time and space in TEI.

There is much to model spatially and temporally. In the 1960s, the Toronto’s gay scene was located on Yonge Street and by the 1970s the bars had migrated north along Yonge from Queen Street towards Wellesley Street. Two of the most famous bars on this strip were the Parkside at 530 Yonge Street and the St. Charles Tavern at 488 Yonge Street, both owned by Norman Bolter. The neighbourhood surrounding the former sites of the Parkside and the St. Charles is currently a site of massive development. Gone are the seedy bars and massage parlours. Large glass condos are rising from bulldozed lots and from the tops of heritage buildings.

The building that housed the St. Charles Tavern still stands above Yonge Street at Wellesley. It is slated to become a condo in 2017, the iconic clock tower that served for decades as a meeting spot for the gay community will be preserved at the base of a proposed 153 metre glass spire. The incorporation of this piece of gay history into a shining skyscraper only furthers serves the ideology that scapegoats the gay community as the root cause of gentrification, making the million dollar condos imagined by a developer seem like an inevitability, rather than just one potential future amongst many. What is lost in this new instance of facadism is the history of the St. Charles Tavern, a violent history neither the city nor developers seem keen to acknowledge or commemorate.

For example, tracing the events outside the St. Charles Tavern on Halloween from 1968 to 1981 reveals Toronto's violently homophobic history, and the inadequate policy and police response to that violence. In the 1960s it was illegal for men to wear clothing of the opposite sex in Toronto, a rule that was relaxed at Halloween. Every Halloween St. Charles Tavern hosted a drag show, and every year a homophobic mob congregated outside the bar to throw eggs and rotten vegetables as the queens arrived. In 1968, police found gasoline bombs behind the tavern, and yet in the following years police still permitted crowds to hurl insults shout slogans such as "kill the queers", and throw debris at the patrons. It took a decade for the police to start arresting people in the mob; in the meantime a volunteer gay defense patrol, Operation Jack O'Lantern, escorted patrons through the neighbourhood and in through the back door of the tavern. Between 1975 and 1978, 14 patrons of Toronto's gay bar scene were murdered. Eight of those murders went unsolved amid accusations of police homophobia, which were only exacerbated by homophobic articles published in the Toronto Police Association Journal. Publishing this history online, not only in text, but in map form, will make it accessible to an audience that will include not just scholars, but the citizens of Toronto. By developing accompanying pedagogical tools to guide users through the map, we hope to engage local residents, as well as the thousands of students at nearby universities and schools, in working to reclaim that lost history, and undoing some of the effects of the gentrification of the mind.

The Bodleian TEI Catalogue Consolidation Project

James C. Cummings
james.cummings@it.ox.ac.uk
University of Oxford, United Kingdom

Andrew Hankinson
andrew.hankinson@bodleian.ox.ac.uk
University of Oxford, United Kingdom

The Bodleian’s TEI Catalogue Consolidation project was a joint Bodleian / IT Services project at the University of Oxford, designed to implement a single consolidated and sustainable infrastructure for delivering TEI manuscript description catalogues. The project incorporated user research, scoping, technical design, implementation, user testing, and subsequent iteration. The aims of the project were to determine a suitable technical architecture for the storage and indexing of TEI manuscript descriptions across multiple collections; engage in user testing of the existing TEI-based catalogues at the Bodleian and decide on the functional improvements required for the front end interface(s); build or implement the ‘back-end’ technical architecture as scoped; build a new, user-friendly interface for searching and browsing TEI; and design and implement a sustainability plan around training, communications and standards.

This poster will concentrate on the technical framework, joint schema design, and legacy data migration of existing catalogues and where this fits in the overall technical systems of the Bodleian Library’s consolidated infrastructure for TEI manuscript description catalogues.

The Bodleian Libraries holds well over 20,000 manuscripts and serves readers from all academic divisions of the University of Oxford as well as thousands of external readers from around the world. More than half of the manuscript collections in the Bodleian are effectively hidden from scholars because they are not described online, or because the existing descriptions are not well indexed or even available to users. To try to solve this problem, the Bodleian spent five years creating TEI-based catalogues for descriptions of its manuscripts. However, the result was eight separate TEI catalogues, the largest of which (FIHRIST) is the union catalogue for the description of Islamic manuscripts in the UK. Seven other catalogues (Hebrew, Armenian, Georgian, Tibetan, Sanskrit, Shan, and Genizah) represent portions of the Bodleian Libraries Oriental collections. The most recent addition is the TEI catalogue for western medieval manuscripts, funded by *The Tolkien Trust*. Prior to the consolidation project, small improvements were made to each subsequent catalogue, but funding was not available to rollout those improvements retrospectively, or to consolidate the code base. TEI is rapidly becoming the

de-facto language for encoding descriptions of manuscripts collections (in the Bodleian and internationally) and this project was an opportunity to build on its use in a concrete way, by providing a clear set of software, guidelines, and training capacities for the large number of staff engaged with describing manuscripts. Consolidating this infrastructure has significantly lowered the operating costs of support and feed directly in the University's strategy for enhancing access to collections.

As part of the project, the existing TEI manuscript description schemas were consolidated into a single TEI customization. By using TEI, the catalogue descriptions were made more easily expandable to include full transcriptions of manuscripts, leading the way towards the mark-up and extraction of important biographical, geographical, and scientific data. In addition the existing catalogue descriptions were migrated to this single TEI customization. As well as showcasing the project as a whole, the poster will focus on the consolidation process including the key aims and objectives of the project, which were:

- To decide on a technical architecture for the storage and indexing of TEI-XML manuscript descriptions across multiple collections.
- Engage in user testing of the existing TEI-based catalogues at the Bodleian to decide the functional improvements required for the front end interface(s).
- Develop a technical requirements document with the necessary details to implement the recommendations during the subsequent buildproject.
- Build the 'back-end' technical architecture as scoped.
- Build a new user-friendly public interface for searching and browsing the TEI.
- Migrate the existing TEI applications into the new solution.
- Design and implement a sustainability plan around training, communications and standards.

The poster will explain the project, the process used for schema consolidation, legacy data migration, and the overall technical infrastructure.

“My Name is Lizzie Bennet”: Reading, Participation, and Jane Austen Across Media Platforms

Meredith Dabek
meredith.dabek@nuim.ie
Maynooth University, Ireland

The Lizzie Bennet Diaries is a digital update of Jane Austen's novel, *Pride and Prejudice*, in which Austen's narrative is reimagined for the twenty-first century through its distribution across multiple media platforms. *The Lizzie Bennet Diaries* (hereafter referred to as LBD) is centred on a series of YouTube video diaries by Lizzie Bennet and includes four complementary YouTube channels, thirteen interconnected Twitter feeds, Tumblr posts, Facebook profiles, and numerous social media interactions and 'conversations' between the narrative's characters and its readers.

This poster expands upon existing research conducted as part of a larger, ongoing PhD research project. It will present a visual overview of LBD and the specific modes of participation available to readers during the narrative's initial release in 2012 and 2013 (an important distinction, since the narrative was originally released as a serial story). Drawing from a sample of LBD reader comments on YouTube and Twitter (using MaxQDA to qualitatively code the comments), the poster will explore how readers participated in the LBD narrative and how their participation may have influenced or affected their reading habits. In addition, Aarseth's cybertext theory and McGann's radial reading theory will provide a foundation for discussing LBD's participatory elements in a theoretical context, with an emphasis on discussing how digital media have invited us to revisit and rework those theories.

According to Aarseth, cybertexts such as LBD invite and encourage readers to make deliberate and intentional choices as they navigate through the text, its multiple entry points, and its various narrative paths (1997). As a result, readers actively participate in shaping their individual reading experience. Thus, LBD reader must decide which elements of the narrative to consume, and in which order: does she choose to follow Lizzie on Twitter, but not Darcy? Does she watch Lydia's YouTube videos, or reblog Jane's fashion posts on Tumblr? Each choice leads the reader in a slightly different direction in the narrative, and provides additional information that offers context and meaning to the core series of YouTube videos. The choices made by readers are also indicative of McGann's theory of radial reading, where readers seek out additional information not immediately available in the core text (McGann 1991). The various modes of participation available to LBD readers, as well as the degree of interactivity implied by cybertext theory and radial reading, gives readers an avenue for active engagement with the narrative and helps reinforce the belief that their contributions to the narrative matter. This belief, what Professor Stephen Coleman calls "*the feeling of being counted*, or the affective character of an experience that renders it fulfilling for individuals" (2013), serves to strengthen a reader's engagement with the text.

Using Aarseth and McGann's theories as a foundation, the poster will consider how LBD's modes of participation might strengthen a reader's engagement with and immersion in the text, and whether immersive digital narratives like LBD can encourage engagement with traditional close reading techniques by prompting individuals to read (or reread) Austen's original *Pride and Prejudice* novel. As Frank Rose, Henry Jenkins and others have pointed out, the Internet has changed readers' expectations from stories and narratives, to the point that many readers of digital narratives now expect some level of participation or interactivity. This poster (and the larger research project) is focused on exploring those participatory elements and their connection to overall digital reading practices.

Towards an Integrated Set of Annotations for Folktales

Thierry Declerck
declerck@dfki.de
German Research Center for Artificial Intelligence University of Vienna, Austria

Introduction

In this poster paper we describe very briefly different layers of annotation for folktales we have been working in the past and which are in the process of being integrated in one set of annotations, which is mediated by a formal representation of the annotation elements in an ontological framework. We list in this short text the various modules of this integrated annotation scheme.

A first approach to the annotation of folktales was done in the context of cooperation between the European CLARIN project and the Dutch Amicus (*Automated Motif Discovery in Cultural Heritage and Scientific Communication Texts,* sponsored by a grant from the Netherlands Organization for Scientific Research, NWO Humanities, as part of the Internationalization in the Humanities programme, from 2009-2012). In this context, we developed an extended annotation scheme for the annotation of folktales with Proppian functions. The scheme includes textual properties, temporal structures, characters, dialog structures, and the Proppian functions (see Declerck et al, 2011 and Scheidel and Declerck, 2010). This scheme was later used for supporting a first information extraction system applied to tales (see Declerck and Scheidel, 2010), and comparing the results of this extraction with manually annotated tales.

Building on this work, an automated linguistic analysis of tales was developed. The goal was not only to detect characters of the tales, but also to provide for a co-reference analysis such that the actions in which the characters are involved can be fully specified, and thus helping for an automated detection of Proppian functions, together with the involved personages. Results of the analysis are stored in a database, which has been further developed onto an ontological framework: Adding thus not only an annotation layer but also a formal representation level (see Koleva et al, 2012, and Declerck et al, 2012). The ontological representation allows also to apply generalisations for the specification of the characters (human vs animals, or supra natural etc.). The system was also able to operate reference resolution of the kind: "daughter" can also be a "sister", etc.

The move to the use of an ontological framework turned out to be very useful, since further work on distinct elements of a tales could be easily integrated. So for example, the work described in Eisenrecih et al (2014) considered the detection of sentiments expressed by the characters of the tales. Such sentiments ("joy", "happiness", "sadness" etc.) could be added in a straightforward manner to instances of characters at the time span in which they occur in the tales. In fact, the work in Eisenrecih et al (2014) mainly addresses the issue of adding Text to Speech (TTS) functionality to the automatic analysis of the text. The TTS system accesses the instances of the characters in the populated ontology and can retrieve the information on sentiment encoded there and correspondingly model the voice output of the various characters (an example using the tale "Frog Prince" can be heard, or preferably downloaded, online).

Very recently, we started also looking at other metadata to be used for annotating folktales, and to see how to integrate those with the Proppian functions. We looked for this at the well-known classification systems of Stith Thompson (1977), Antti Aarne (1961) and Hans-Jörg Uther (2004) and we are starting to integrate those models in our ontology. The resulting ontology from the Thompson Motif Index has been presented in Kostova and Declerck (2016). Additionally we linked the detected characters to WordNet, investigating if this can help for the disambiguation of characters (Declerck et al, 2016).

As the most recent work we dedicated to the folktale topic dealt with with the implementation of running systems, less attention was given into the extension of the annotation scheme, work which is currently underway and which we present as a poster at DH 2017.

Introduction

We report on the work of a recent HathiTrust Research Center (HTRC) task force charged to draft an actionable, definitional Non-Consumptive Use Research Policy. As the research division of HathiTrust, the HTRC facilitates computational text analysis of materials in the HathiTrust Digital Library (HTDL) by adhering to a non-consumptive research paradigm. As the HTRC has integrated the text of the full HTDL corpus into its datastore, it has become increasingly important to clarify and codify the Center's policy for non-consumptive research. The task force, which consisted of copyright and scholarly communications librarians and representatives from HathiTrust operations and the HTRC, recommended a policy that clarifies acceptable researcher behavior and allowable exports from the HTRC Data Capsule (Plale, et al., 2015). This poster describes the task force's work to establish a Non-Consumptive Use Research Policy for the HTRC that aims to achieve the same goals as copyright itself: to promote progress in the discovery and spread of knowledge, without harming the commercial interests of authors, publishers, and other stakeholders.

Background

While the concept of non-consumptive research has seeded the mission of the HTRC, the Non-Consumptive Use Research Policy task force sought to translate conceptual definitions of the term into practicable policy (Bhattacharyya, et al., 2015). When first used in 2010, the term was defined as "research in which computational analysis is performed on one or more Books, but not research in which a researcher reads or displays substantial portions of a Book to understand the intellectual content presented within the Book" (Amended Settlement Agreement: Authors Guild, Inc., et al., v Google Inc., 2009). Since then, legal scholar Matthew Sag and literary scholar Matthew Jockers have offered their own definitions and assessments, tending to favor instead the term *non-expressive use* (Sag, 2012; Jockers, 2013). Several recent court decisions pointed the task force toward the current legal understanding of non-consumptive research specifically and current interpretations of fair use broadly (Authors Guild v HathiTrust, 2014; Cambridge University Press v Becker, 2016; Fox News Network v TV Eyes, 2014). Additionally, the task force looked to existing access models for restricted data (ICPSR) as well as professional guidelines for non-consumptive research (Association of Research Libraries, 2012; Cox, 2015).

Policy Highlights

The group first created a framework drawing on fair use that, when paired with the HTRC technical infrastructure, would clarify non-consumptive access to the HTDL. This framework accounted for several considerations and safeguards:

- Mechanical data mining differs from researcher-driven computational text analysis, which requires interplay between scholar and text.
- Current case law suggests that it needs to be sufficiently difficult, but not strictly impossible, to reconstruct the expressive work (Authors Guild v Google Books, 2015).
- Users must agree that they will not treat HTRC tools as a reading application, and the tools should periodically remind them of this limitation.
- The HTRC must continue to block through technological measures and human review the export of protected textual data from the secure system.

The task force then drafted the HTRC Non-Consumptive Use Research Policy (HathiTrust, 2017). It defines non-consumptive research as "Research in which computational analysis is performed on one or more volumes or textual objects in the HTDL, but not research in which a researcher reads or displays substantial portions of an in-copyright or rights-restricted work to understand the expressive content presented within that work." Of key importance is the notion of substantial portion, which, according to the policy, is a portion of the work sufficient in quality or quantity to provide a substitute for access to the expressive content of the original text. The policy outlines acceptable in-capsule uses of corpus text that are limited to those which would facilitate scholarly text analysis, including checking results to refine algorithms. In addition to enumerating non-consumptive research practices—for example text extraction, textual analysis, and automated translation—the policy provides sample results that further model approved uses. These results, which may be exported from the HTRC Data Capsule, include non-binary, human-readable statistical summaries, derived results, keywords-in-context, and concordances that are not sufficient to reconstruct a substantial portion of the text.

Conclusions

The task force tailored the policy to address current infrastructure within the HTRC, both technical and human, as opposed to accounting for prospective updates to interface and design. As such, the policy is an iterable, living document that must be revisited as HTRC systems are further developed. Such technical developments, such as the HTRC's exploration of machine-aided results verification to augment the current human-review system, will improve the scalability of the HTRC Data Capsule and may require updates to the policy. As more researchers interact with the HTRC Data Capsule, their use cases may prompt additional refinement of the policy, especially in the exemplar results it provides. The process followed in developing the policy, as well as the guidelines themselves, may be useful in other text mining research environments. They encourage an interpretation of non-consumptive research that values scholarship and intellectual progress, while still balancing the restrictions imposed by copyright law.

In the History of Art, the shaping of aesthetic forms, the transfer of the stylistic languagem and the change of styles have always been at the heart of the discipline. The co-occurrence of aesthetic forms in multiple modi (such as architecture, applied arts, graphics and textual description) or in larger bodies of artefacts has been researched to a lesser degree. Instruments and methods from the field of the Digital Humanities are now opening up pathways for a new understanding of such issues by supporting hermeneutic understanding with quantitative means.

Such instruments are particularly valuable for researching far reaching aesthetic movements such as Neoclassicism (ca. 1760-1860). The Neoclassic movement was of almost global scale – affecting architecture and design from Sidney to New York, and from Athens to the outreach of the Russian Urals – while relating to a common reference in Classical Antiquity, therefore making it an almost ideal topic for studying processes of stylistic transformation.

Here, we present the Neoclassica research framework (The Neoclassica Project, 2017), aimed at providing historians and art historians with new instruments and methods for analysing and classifying material artefacts and aesthetic forms. Initially we are focusing on works of applied art (for instance furniture and furnishings) as well as architecture, following the preliminary hypotheses that these modi show aesthetic forms in close communication with one another due to constructional commonalities and their shared reference of the Classical. While these forms show a trove of similarities across a huge geographic range they also diverge due to local traditions, needs and limitations or political conditions supporting the use of particular vocabularies of aesthetic forms.

We consider it most promising to follow these trajectories in a fresh way, applying the instruments provided by the Neoclassica system, joining a top-down approach harnessing the domain expert knowledge and a data-driven bottom-up approach exploiting the powers of computationally processing large amounts of data.

Specifically, the top down approach comprises a formalized knowledge-representation based on a newly developed ontology for classical artefacts and the semantic annotation and curation of a specifically developed corpus of images and texts done by experts.

The Neoclassica ontology aims to establish a controlled vocabulary that will be both research oriented and multilingual, while at the same time taking into account the different shape of the represented concepts in different languages, specifically in English, French and German (Donig, Christoforaki & Handschuh, 2016). The concepts and terms used to describe artefacts and their structure are based on period sources such as such as for instance Charles Percier's and Pierre François Léonard Fontaine's or Thomas Sheraton's pattern-books or George Hepplewithe's treatise on interior decoration (Hepplewhite, 1794; Sheraton, 1802, 1803; Percier, 1812) reflecting the conceptual control over the production of artefacts.

Since January we started the development of a semantic annotation tool for image corpora. The initial corpus sources will be commercial providers like Auction Houses but we also strive to include coherent ensembles. For this we have for instance a partnership for digitizing the interiors and furnishings of the Dessau-Wörlitz UNESCO World Heritage Site. The digitization and annotation will be done in collaboration with the chair for Visual Studies and Art History of our University. We conceptualize the process of corpus annotation to be in a constant dialog with the ontology development, so that the findings of domain experts curating the data will enrich the perception for the overall domain.

The bottom-up approach, on the other hand, is data-driven in the sense that it employs Deep Learning and Distributed Semantics algorithms for knowledge extraction and classification from images and text corpora (Bermeitinger, Donig, Christoforaki, et al., 2017). We apply a Deep Learning algorithm for classifying features in digital images of classical artefacts like furniture, works of applied art and architecture. We tested the algorithm in a trial image corpus with coarse label annotation for the image as a whole (The corpus and accompanying source code can be downloaded from The Neoclassica Project, 2017). Currently we are slowly progressing to a more refined feature annotation trained on a corpus annotated by experts using the ontology.

Knowledge discovery in text corpora is divided into Named Entity and Relationship extraction mechanisms, already robust in English and rapidly evolving in the German language. This is complemented with a schema agnostic natural language query interface. These modules are part of the in-house developed open source system StarGraph (Lambda3 Project, 2017) capable of processing both structured and unstructured data.

We aspire for the Neoclassica framework to become the centre of a sustainable, open community of scholars with a multitude of disciplinary backgrounds from both the humanities and computer sciences, making it an amalgam system that combines the best of two worlds.

Authorship of Dream of the Red Chamber: A Topic Modeling Approach

Keli Du
keli.du@stud-mail.uni-wuerzburg.de
University of Würzburg, Germany

Dream of the Red Chamber (DRC, 红楼梦) is one of the most famous Chinese classic novels, written by Cao Xueqin (曹雪芹) during the 18th century. The original version of DRC had 80 chapters. But in 1791, Gao E (高鹗) and Cheng Weiyuan (程伟元) claimed that they had found more manuscripts of Cao and published another edition with 120 chapters. Since then, there has been a lot of discussions regarding the number of authors of DRC. Many scholars see the last 40 chapters as a later addition. Currently Hu Shih's (胡适) (Hu, 1988) research is most widely accepted, where he argued these last 40 chapters were written by Gao E. According to some modern research approaches, the first

80 and the last 40 chapters are written by two authors. Evidence also suggest that Chapters 64 and 67 may not be written by Cao (Hu, Wang, & Wu, 2014; Tu, & Hsiang, 2013).

Using Delta (Burrows, 2002), a measure of difference between two texts, the same conclusion has been obtained (Du, 2016). The 120 chapters are written by two authors. Red texts are the first 80 chapters and green texts are the last 40 chapters. Delta also suggest that chapter 6, 10, 11 and 67 might be written by the second author (see Fig. 1, 2, 3).

Although most the results obtained are within expectations, the presence of the four chapters in the second group certainly deserves further investigation. Three hypotheses are proposed in this paper as the cause for this situation:

- This test result from the Delta method is not 100% accurate.
- These four chapters shares many names or plot related terms with the last 40 chapters.
- Stylistic difference. Compared to the other chapters, the use of some less plot related terms indicates that the second author wrote Chapter 6, 10, 11 and 67.

Topic Modeling was used to test DRC on this regard. I used the version of the DRC that Tu (2013) deemed “the closest to the earliest editions” for this study. Topic Modeling can automatically discover the contents of a large collection of documents, and is often used as an alternative method to explore the documents. A topic is a probabilistic distribution over words appearing in the corpus. The model finds groups of related words, and words that occur frequently together will be clustered in the same group. If some words tend to co-occur in the last 40 chapters of DRC, Topic Modeling would be effective in highlighting their presence. LDA (Latent Dirichlet Allocation) (Blei et al., 2003) was used to model my corpus and do my test, and MAchine Learning for LanguagE Toolkit (MALLET) was used as the topic-modeling tool.

At the preprocessing step, tokenizing and chunking were performed. Tokenizing is required to process texts written in the Chinese Language to spilt texts into words, as there are no spaces to mark word boundaries. Tools like Stanford Chinese Word Segmenter can only be used on modern Chinese texts, as the segmentation standards are not suitable for classic Chinese. Character bigrams were hence selected as the “word”. Breaking the texts up allows the relationship among words to be explored more thoroughly, hence the chapters were split, where each document for the test contains 500 bigrams. Stopwords present another issue. A test run was first performed with MALLET to acquire some topics. The results of the test run show the bigram words assigned to the topics. In these topics the correct bigram words and person names were observed. Besides, a significant amount of meaningless bigrams in the topics were also found, for example: 著一 (writings, one), 的干 (and so on, do), 云笑 (cloud, smile). Thereby a stopword list with the following was compiled: a collection of meaningless bigrams and person names and function words like 一個 (a), 這個 (this), 只得 (have to) and so on.

MALLET was run after the preprocessing stage to generate 50 topics. The topic-document distribution output was aggregated as the chapters were split into chunks at the preprocessing step. The average of the topic shares associated with each chapter were then computed and the shares were transformed into a document-topic matrix. Then the visualization of the topic proportions associated with the chapters was created (see Fig. 4). The x-axis are the topics and the y-axis are the documents. The red line divides the figure into two parts, the first 80 chapters (above the line) and the last 40 chapters (under the line). Topic #26 became the main focus from this result: the last 40 chapters are all strongly associated with it, while the first 80 chapters (except Chapter 11 and 67) are associated to this topic with much lower probability. The topic-word assignments were then computed. The top 20 words and their unnormalized weights of the topic #26 are:

> 357.0: 太太 (lady), 246.0: 回來 (back), 233.0: 來了 (coming), 218.0: 丫頭 (slave girl), 190.0: 過來 (come over), 184.0: 答應 (answer), 146.0: 只見 (seen), 125.0: 去罷 (go), 122.0: 時候 (moment), 114.0: 叫人 (call someone), 108.0: 出來 (come out), 101.0: 言語 (speech), 100.0: 告訴 (tell), 98.0: 今日 (today), 98.0: 話儿 (talk), 95.0: 看見 (see), 92.0: 回道 (answer), 91.0: 那邊 (over there), 91.0: 連忙 (promptly), 85.0: 想起 (think of)

All the words are not person names or plot-related. The result obtained from the Topic Modelling shows that Topic #26 is a “style”-Topic. Most of them can be presented in a scene: an interaction (or a conversation) between the lady and the slave girl. DRC is an observation of the Chinese society in 18th-century. The story is about the life of two large, wealthy family compounds in the capital of China. Such scenes or plot are hence very common in the whole novel.

In conclusion, Topic Modeling was used in this paper to find the specific topic, which represents the difference between the first 80 and the last 40 chapters of DRC. The test results indicate that both hypotheses, a) the Delta test result is not 100% accurate, b) The four chapters share many names or plot related terms with the last 40 chapters, are not true. The first 80 chapters (except Chapter 11 and 67) are stylistically different from the last 40 chapters. According to the results of Delta and Topic Modeling, both Chapter 11 and 67 are definitely not written by the first author. They might be written. or at least edited by the second author of DRC.

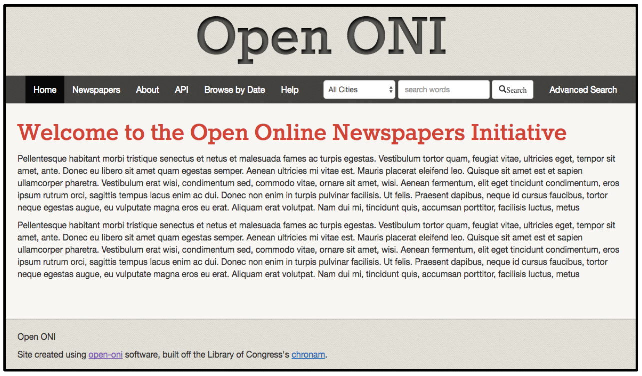
The Open Online Newspaper Initiative (Open ONI) is an open source collaboration whose goal is to lower the entrance bar for libraries, archives, historical societies, and other cultural heritage institutions to display digital newspaper content. Open ONI was formed in response to a need for free, easily deployed, flexible, plug-and-play software that is useful for collections large and small, local and national.

Open ONI's code base was forked from the Library of Congress newspaper application, chronam (Library of Congress, 2016a). chronam was created to support the National Digital Newspaper Program (NDNP), a national project supported by the Library of Congress and the National Endowment for the Humanities, which seeks to digitize and add titles to a searchable, online collection at Chronicling America (Library of Congress, 2016d; 2016b). State entities often have newspaper content which they are unable to put online through Chronicling America and must seek a different solution to present their digitized periodicals (Library of Congress, 2016c; Center for Research Libraries Global Resources Network, 2015). The Library of Congress released the source code for chronam to help address this problem. The software currently available on GitHub requires skilled technical staff to customize the application and update related code packages, which can be a barrier for small institutions. Open ONI was born in 2015 when a group of librarians, project managers, and developers working on their own chronam installations gathered to discuss a friendly fork of the software. In the process of setting up, deploying, and customizing chronam for their own newspaper sites, Open ONI members had identified many shared interests, from fixing common bugs to building new features, and decided that pooling their resources and efforts to develop an application to fit the majority of their needs would benefit them all. Though we are currently working towards meeting our own implementation goals, we are keeping in mind how this might be applicable to others in the future.

Since beginning the initiative, Open ONI developers have made substantial changes and improvements to the initial chronam code. The web framework, Django, has been updated to the latest long term support version, and many supporting libraries and command line tools have been updated or replaced, when existing libraries and tools were deprecated or no longer available. Perhaps the largest improvement is the incorporation of the RAIS image server, an International Image Interoperability Framework (IIIF) compliant image server developed by the University of Oregon Library to deliver JP2s nearly as fast as chronam delivered TIFFs, but using a fraction of the RAM (Echols and Krech, 2016). RAIS is a 100% open source alternative to other JP2 image servers. With contributions from the Maryland Institute for Technology in the Humanities (MITH) at the University of Maryland, and sponsored by the IIIF-Consortium, Open ONI offers IIIF compatible URLs to allow the substitution of other image servers. Beyond existing interoperability formats such as MARC and linked data, future plans could include IIIF manifests and other metadata formats/downloads, depending on developer time. Open ONI's developer environment relies on Docker containers to separate the different components of the software and provide a one-line setup command. The application is configurable through settings files and personalizable, with a default theme that users may copy to get started on their own look and feel. Additionally, Open ONI offers several plugins that users can incorporate into their site such as featured content, randomly selected newspaper pages, and a customizable map. A recent feature allows for defining copyright statements by publication and date range, and showing these statements directly below each page.



Welcome to the Open Online Newspapers Initiative

Open ONI

Site created using open-oni software, built off the Library of Congress's chronam.

Three states have plans to redeploy their newspaper sites with Open ONI in 2017: The University of Nebraska, University of Oregon, and Penn State University. Features that will be developed before all three launch their sites include extending the advanced search features for pages and newspaper titles, reinforcing the current test suite, updating the search engine from Solr 4 to Solr 6, and developing documentation to help organizations migrate from chronam to Open ONI.

Our poster will cover the above improvements of Open ONI, as well as the road map for future work. We will also have an instance of Open ONI available at the conference which will demonstrate the speed of the RAIS image server for JPG 2000s, default theme, new advanced search, and plugins. We hope that Open ONI offers organizations with newspaper collections of all types a reliable and customizable option for presenting and searching their collections. This poster presentation is also outreach to gain support and input from the archives, library, historical society, developer communities and others.

This poster presents the work completed to date on *Go Queer*, a ludic, locative media experiment and experience that occurs on location, in the city, on the playful border between game and story, the present and the past, the queer and the straight, the normative and the *slant*. The app takes the city of Edmonton’s queer history as its text, and produces a locative, spatialized narrative of that history by displaying text, images, video and audio in place at the actual locations where they occurred, thus creating what Richardson and Hjorth (2014, 256) and call “the hybrid experience of place and presence.” The app invites its users to drift queerly through the city, discovering the hidden histories that always surround us, yet somehow remain just beyond our apprehension. The app compiles these traces into a media layer that augments quotidian city space, juxtaposing the past onto the present, creating a deep, queer narrative of place. By bringing together the physical navigation of the contemporary city with the imaginative navigation of its queer past, the app enacts a praxis that we characterize as a queer ludic traversal, one that renders the navigation itself as queer as the content that it presents. In so doing, the app produces the experience of *place*, in Lucy Lippard's (1997) formulation that

> Place is latitudinal and longitudinal within the map of a person's life. It is temporal and spatial, personal and political. A layered location replete with human histories and memories, place has width as well as depth. It is about connections, what surrounds it, what formed it, what happened there, what will happen there. (7)

This poster highlights four foundational questions of *Go Queer* that serve as base from which we research, write, and build:

Why a "game" for queer history?

Games have the unique affordance of putting players/readers into a first-person relationship with content, where they expect to actively interact with, and manipulate it. *Go Queer* seeks to generate the affective experience of queerness, to show and not just tell the queer history of the city, to collapse the distance between the present and the past. The game proceeds according to a procedural rhetoric that argues, in Sarah Ahmed's words (2006, 563), that "queers are differently 'oriented' to a spatial world that is the product of extended and extensive heteronormativity."

How can we encode a queer sense of place and co–presence in the contemporary city?

Thinking through the implications of "orientation" makes locative media a logical choice of format. It allows us to create a mimetic experience, where the player experiences the juxtaposition of queer space/time simultaneously with contemporary, normative space/time. The result of this juxtaposition is, we argue, a particularly powerful form of affect, where the player/user experiences the paradox of queer space: that it is always simultaneously both queer and not queer, slant and straight, persistent and fleeting.

How can we integrate crowd–sourced materials effectively and ethically?

Queer places are, by definition, sites of accretion, where stories, memories, and experiences are gathered. Queer place, in particular, is reliant on ephemeral histories, personal moments and memories. That *Go Queer* must integrate these personal archives is apparent, yet we must also be diligent about our ethical relationship to the material. How can we ethically solicit, verify, and evaluate community contributions to our history?

What technological structures will facilitate our goals?

The project requires both flexibility and stability. In order to offer the greatest flexibility to the interface, but the most stability to the actual content, we have decided on a custom server wrapped around a core GIS server. The GIS server will host the stable database; the custom wrapper will allow the flexibility to: a) customize and change the behaviour of the app as needed without modifying the underlying data structure; and b) input the primary materials into the database via a simple form-based interface.

We expect to have a functional beta version in place by DH 2017. A final production version should be launched in summer 2018.

Toward a Typology of Digital Thematic Research Collections

Katrina Simone Fenlon
kfenlon2@illinois.edu
University of Illinois at Urbana-Champaign
United States of America

Introduction

This paper considers an evolving genre of digital scholarship in the humanities, the thematic research collection, which is distinguished among other kinds of scholarly production as a collection of primary sources, gathered by scholarly effort and made available online to support research on a theme (Palmer, 2004). There are hundreds of such collections on the Web, ranging from well-known digital archives to small collections of historical or literary evidence within a thematic niche.

Despite recognition of the genre (e.g., Price, 2009; Flanders, 2014; and Thomas, 2015), we do not know enough about this mode of production, how it contributes to humanities discourse, or how it relates to systems of peer review, discovery, and long-term maintenance. The evolution of public-facing humanities scholarship, long-term access to collections, and the completeness of the scholarly record depend in part on a more systematic understanding of this and other emergent genres.

Through typological analysis, this research aims to build a foundation for rigorous study of thematic research collections. The goals of typology are to understand the breadth and variety of a genre, and identify unanticipated variations. We take up the following questions: What types of collections can we usefully distinguish, and what can these types and their characteristics reveal about the challenges and opportunities confronting the growth of digital scholarship in the humanities?

Method

We conducted a pilot survey of the digital humanities landscape to identify a set of resources meeting our definition. Sources for the survey included digital humanities centers, library publishing programs, tools and platforms for digital publishing, and scholarly collectives/peer review organizations. While not comprehensive of the digital humanities landscape, the survey produced a set of 98 diverse collections.

Our typology followed the formal process described by Kluge (2000):

1. Develop relevant analyzing properties. Properties reflect our intuitions about interesting differences between collections, within this context of scholarly work and use.
2. Group members by distinct combinations of properties.
3. Analyze meaningful relationships and construct types.
4. Repeat earlier steps if needed to accommodate collections that do not fit.

We iterated our analysis, refining our sense of properties and resultant types, until we were satisfied that our types speak to important and revelatory differences among collections.

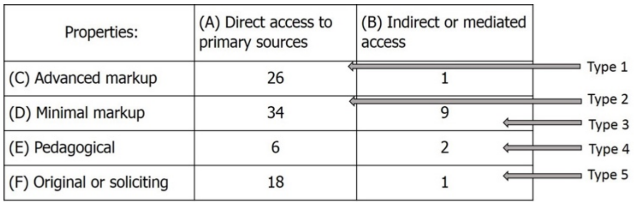
Analysis

Our proposed typology of thematic research collections relies on the following four properties of collections, which are basically determinative of their potential uses: (A) Whether primary sources are the main content of the collection, or are ancillary; (B) Whether the collection employs advanced markup, to enable use beyond basic keyword search; (C) Whether the collection's primary purpose is pedagogical; and (D) Whether the collection solicits, or actively engages in the collection of new or original evidence.

The 98 collections in our set resolve into 5 types, per different combinations of these properties. Figure 1 shows how types are derived from a matrix of properties, along with the number of collections that fall into each type. Figure 2 visualizes the types in a projected, three-dimensional property space.

We can briefly describe the types as follows:

- Type 1. Traditional collections with enabling markup: Marked-up (usually textual) primary sources constitute the main content of the collection, and are accessible directly by search and other functionalities.
- Type 2. Traditional collections without enabling markup: These are more heterogeneous in content, but primary sources are still directly accessible as such.
- Type 3. Data-centric or derivative-centric collections: While primary sources are a major component, they are not directly accessible as such. Rather, access is mediated by an analytic or interpretive layer, such as an interactive map or 3D model.
- Type 4. Pedagogical collections: They resemble one of the above types, but are distinguished by their intended purpose and audience.
- Type 5. Original or soliciting collections: They resemble one of the above types, but are distinguished by the scope and processes of their development (specifically, they are collecting new primary sources).



Properties:	(A) Direct access to primary sources	(B) Indirect or mediated access
(C) Advanced markup	26	1
(D) Minimal markup	34	9
(E) Pedagogical	6	2
(F) Original or soliciting	18	1

Type 1
Type 2
Type 3
Type 4
Type 5

Figure 1. Property matrix indicating numbers of collections in each type

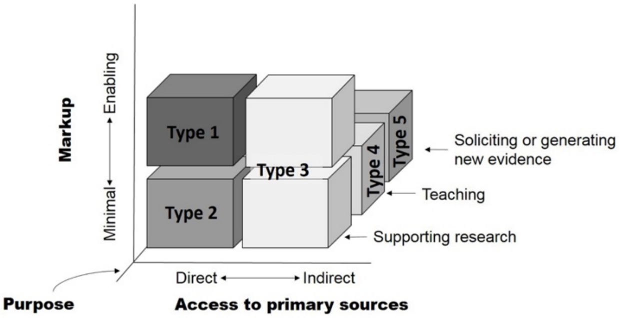


Figure 2. Types visualized in three-dimensional property space

Discussion

We hope the systematic identification of properties of a broad range of collections and preliminary types may serve as a foundation for ongoing study of how collections work, and how they may be served (or not) by systems of evaluation, discovery, and long-term maintenance. The full version of this poster details methods, properties, and types with vivid examples, and considers the implications of types for effective and ongoing access to collections.

Modelling a Prosopography for the Roman Republic The Digital Prosopography of the Roman Republic Project

Luis Figueira
luis.figueira@kcl.ac.uk
King's Digital Lab
King's College London, United Kingdom

Miguel Vieira
jose.m.vieira@kcl.ac.uk
King's Digital Lab
King's College London, United Kingdom

In this abstract we describe the development of a web application for a prosopography of the Roman Republic, focusing on the data modelling, data harvesting and user interface. The web application offers fine-grained data about the elite of the Roman Republic, allowing the detailed study of its attested individuals, including familial composition, office-holding patterns, internal hierarchies, property and wealth.

The Digital Prosopography of the Roman Republic (DPRR) is an AHRC (Arts and Humanities Research Council) funded project, running from 2013 to May 2017. It is a collaborative project being developed by King's Digital Lab, together with the Classics and the Digital Humanities Departments from King's College London.

The project was developed to allow users easy access to complex data to enable them to answer questions such as:

- list the individuals who were praetors between 200-100 BCE with nomen Caecilius;
- list proconsuls in Gallia between 100-80 BCE;
- show all persons who were both consul and pontifex between 123 and 100 BCE (i.e. consuls who were also pontifices);
- visualise the composition of the the senate in the year 100 BCE;
- persons with a birth date and a death date between 250-100 BCE;
- women that died of violent death.

To preserve the richness of the data, while allowing answering research questions as above, the DPRR data model was designed to store the prosopographical data using the principles of the Factoid Model (Bradley and Short, 2002; Pasin and Bradley, 2012). This builds upon previous experience acquired developing similar projects (Prosopography of the Byzantine Empire, Clergy of Anglo-Saxon England Database, Prosopography of Anglo-Saxon England, Prosopography of the Byzantine World, People of Medieval Scotland, Making of Charlemagne's Europe).

The data model is organised around four main entities: *Person*, *PostAssertion*, *StatusAssertion* and *RelationshipAssertion*. The main entity, *Person*, stores information about each individual, such as names, gender, life dates, patrician indicator, etc. The *PostAssertion* entity stores data related to offices/posts held by individuals (such as praetor, consul, legate, etc), while the *StatusAssertion* stores senatorial and equestrian class information. The *RelationshipAssertion* represents personal relationships (brother of, son of, etc), connecting two different individuals within the database. All these entities are linked, as represented in Figure 1. All Assertion models are linked to a *SecondarySource* entity with details about the bibliographical references supporting the data.

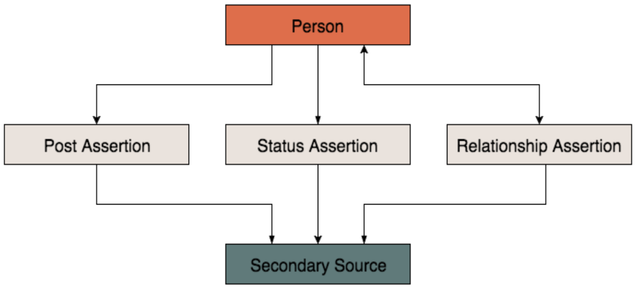

Figure 1 – Simplified database model

The data for the project has been harvested from multiple sources – mainly from Broughton's Magistrates of the Roman Republic (1951-86), Ruepke's Fasti Sacerdotum (2005) and Zmeskal's Adfinitas (2009). The data was automatically loaded using scripts developed for each source (Fig. 2). There's also a data editing interface, which was mostly used to make corrections to the automatically loaded data, as well as adding new information when needed.

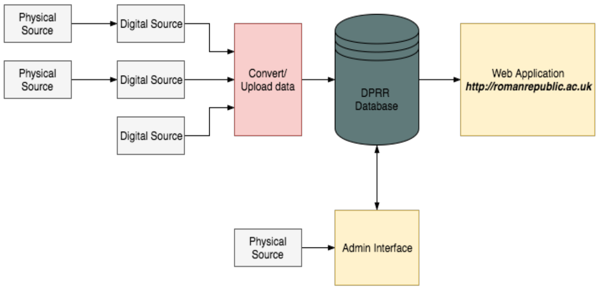

Figure 2 – Data workflow

Besides loading and entering data directly into the database, the project also has rules to infer new information about personal relationships and senators. An example is, the application creates a Senator object for a person that held a specific post in a given year, such as consul, praetor, aedile, tribunus plebis, censor, princeps senatus.

The database, which stores all this information in an easily searchable format, is fronted by a web application (see the public version of the website). This website allows the public to explore the data using a faceted search interface with different filters that can be applied. This guides the user to achieve answers to the research questions above. By selecting individual results, it is possible to see all the information about a person, including visualisations of their relationship networks (Fig. 3).

Visualisations of the senate composition on a yearly basis are also being created. We are currently working towards integrating the database with Linked Data technologies as part of the Standard for Networking Ancient Prosopographies (see the SNAP:DRGN project).

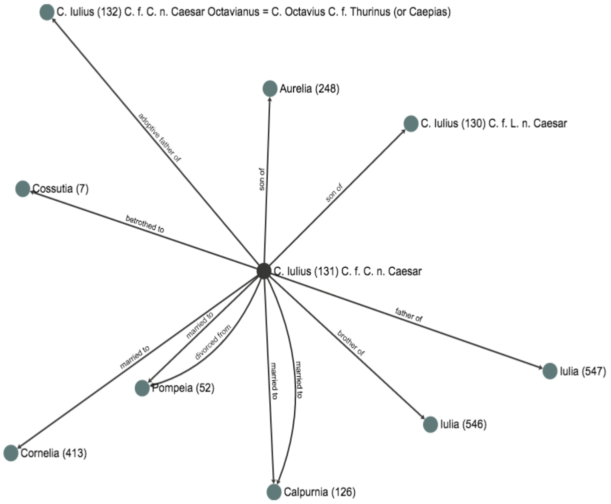

Figure 3 – Network visualisation for *C. Iulius (131) C. f. C. n. Caesar*

The project is built using open source tools and technologies, mainly the Django application framework with a PostgreSQL database. The search interface is implemented using the Solr search engine together with the django-haystack search package for Django. The visualisations are created with *d3plus* and *linkurious*. The project source code is also available as open source in a GitHub repository.

Our poster will illustrate the model that supports this digital resource, the methods used to retrieve the data and populate it, as well its usage for data exploration and visualisation.

Re(a)d Wedding: A Comparative Discourse Analysis of Fan Responses to Game of Thrones

Eric Forcier
School of Information Studies
Charles Sturt University, Australia

It is no exaggeration to say that HBO's *Game of Thrones* is more than just a television series or a successful brand: it is a transmedia system in the sense first used by Marsha Kinder (1991) and popularized by Henry Jenkins (2006), in which media-hopping networks of intertextualities extend the "storyworld" of an original production. Now spanning six seasons and 60 episodes, with an average global viewership (from its most recent season) of 25.1 million viewers per episode (Shepherd, 2016), it has spawned five video games, a graphic novel adaptation, several companion books, two rap albums, a 28-city orchestral tour, a wide variety of tabletop games, toys, merchandise and mobile apps, and countless podcasts, fanfics and other fan-based creations. Given the volume of content this represents, it is easy to forget that the television series itself is an adaptation of a book series with a pre-existing fandom. As such, the *Game of Thrones* storyworld represents a remarkably rich and challenging environment for fans old and new, who must negotiate an increasingly complex network of paratexts and intertexts in order to fully engage with its narratives.

In this sense, fans of the series represent an emerging model for cultural consumption that should be carefully explored. Transmedia systems, like that exemplified by *Game of Thrones*, are becoming increasingly prevalent (e.g., *Star*

Wars, Harry Potter, The Walking Dead, the Marvel Cinematic Universe, etc); these systems demonstrate, in microcosm, the global challenge of managing the fire-hose flow of information in contemporary postdigital society. The study of how people, as fans, access and manage information within a transmedia system provides valuable insight that contributes not only to practitioners and scholars of the media industry, but to the wider context of cultural studies, by offering findings on this new model of the fan as consumer and information-user. For us, as digital humanists, defining the "transmedia fan" is of particular relevance as we seek to understand contemporary social and cultural transformations engendered by digital technologies.

Methodology

As a first step in defining the "transmedia fan", the current project undertakes a comparative discourse analysis of online conversations of *Game of Thrones* fans. One of the most dramatic plot developments in the source material (Martin, 2000) was adapted to the screen in the penultimate episode of the third season, "The Rains of Castamere" (Benioff & Weiss, 2013). Readers of the book series had long anticipated and dreaded the events of the "Red Wedding", while fans of the show unfamiliar with Martin's narrative were largely taken unawares by the pivotal episode.

Since the television series' inception, writers at *The AV Club* have written two critical reviews for each episode: one for viewers familiar with the books (i.e., "Experts") and one for viewers unfamiliar with the books and averse to "spoilers" (i.e., "Newbies"). What results are two completely separate reviews of "The Rains of Castamere" which in turn document the fans' reactions to the episode in the form of user comment threads: one comment thread where fans were expected to be shocked by the outcome of the episode and one comment thread where fans had hotly anticipated it.

As a pilot project, the current work takes the content of both comment threads—a corpus of approximately 5,600 comments—and analyzes each thread separately using a qualitative coding method aligned with constructivist grounded theory (Charmaz, 2006). Through this analysis, a categorization of themes emerges illustrating tactics for negotiating intertexts and paratexts unique to each group of fans. These themes fall under two broad categories: sentimental negotiation (i.e., emotional responses) and tactical negotiation (i.e., cognitive, or reasoned responses). A comparison of categories and sub-categories between both groups provides preliminary findings to support an emergent model, or models, of the "transmedia fan".

Conclusion

The present research represents a first step in exploring the impact of transmedia systems, as exemplified by *Game of Thrones*, through the study of fans. The question posed by this research is, fundamentally, an examination of how the problem of "access" is framed in postdigital society from the perspective of the consumer. Future research should explore the negotiation tactics observed in transmedia fans using the principles of De Certeau's (1984) everyday life practice, in order to extend its application to the broader context of modern-day consumers. The current study will contribute to the development of further qualitative and quantitative research that will more clearly define the information behaviors of the transmedia fan. This project is of relevance to researchers in media studies, fan studies, information studies and digital humanities

OBSERVATÓR!O2016

Julia Gianella
julia@impa.br
Instituto de Matemática Pura e Aplicada, Brazil

Luiz Velho
lvelho@impa.br
Instituto de Matemática Pura e Aplicada, Brazil

This poster focuses on OBSERVATÓR!O2016, a web-based platform for collecting, structuring and visualizing the online response to Rio-2016 from content shared on Twitter. This project was developed at the Vision and Computer Graphics Laboratory and is based on two cross related research lines. First, the conception and design of the OBSERVATÓR!O2016 website, which provides a space to explore comments and images about the Olympics through structured visualizations. Second, the ongoing deployment of research regarding the application of a digital method to explore large sets of images. The goal is to highlight how we use *Deep Learning* applications - such as automatic image classification - and visualization techniques to enhance discoverability and expression of subject features within an extensive image collection.

Method: *Deep Learning* and mosaic visualization

OBSERVATÓR!O2016 collected around 1 million tweets from April 18th to August 25th, 2016. In other to gather different perspectives on the debate about the Olympics we created seven Twitter search queries. The data was presented in eight interactive visualizations:

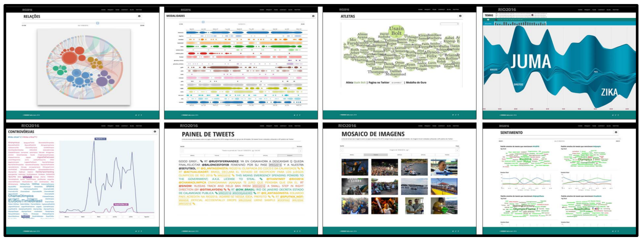

Figure 1. Visualizations

Approximately 180,000 of the collected tweets included unique images. The production of large sets of digital images inaugurates new avenues for researchers interested in the human creative practice. In this sense, the investigation of Lev Manovich on digital methods to study visual culture is quite relevant. With this in mind, we explored Rio-2016 images through *Deep Learning* approaches. As the investigation is currently ongoing, we will report the research process of a single task, which resulted in the *Torch Mosaic* visualization.

During the pre-Olympics, it became evident that many of the images gathered by our query scripts were related to the Olympic torch relay and depicted the iconic object. Part of these images were accompanied by texts that mentioned the torch, but not all. In addition, some tweets mentioning the torch relay incorporated images that didn't depict the object. In other words, text analysis alone was not sufficient to detect a set of images containing the torch.

Thus, we referred to a *Deep Learning* approach to recognize the Olympic torch in our database. The field of visual pattern recognition has been recently improved by the efficient performance of *Convolutional Neural Networks* (CNN). In 2012, the work of Krizhevsky et al. on training a deep convolutional neural network to classify the 1.2 million images in the *ImageNet* LSVRC-2010 contest into 1000 different classes had a substantial impact on the computer vision community.

More recently, and thanks to Google, computer vision tasks such as image classification have become more accessible and applicable. That's because the company released last year their open source software library *TensorFlow.* This library runs code for image classification on *Inception-v3* CNN model, which can be retrained on a distinct image classification task (this quality is referred to as *transfer learning*). By creating a set of training images, it is possible to update the parameters of the model and use it to recognize a new image category. That said, we retrained the network by showing it a sample of 100 manually labeled images containing the torch. Finally, the retrained network ran over our database and returned a set of images with their corresponding confidence score for the new category.

Figure 2. Confidence score over 83%

Until June 25th, around 1500 images with over 85% confidence score for the Olympic torch category had been classified by our network. We used them to create a mosaic visualization that can be zoomed and panned. The mosaic idea is that, given an image (target image), another image (mosaic) is automatically build up from several smaller images (tile images). To implement the mosaic, we used a web-based viewer for high-resolution zoomable images called *OpenSeadragon*.

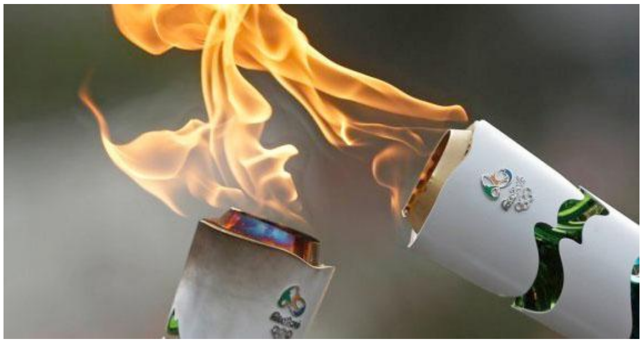

Figure 3. The target image

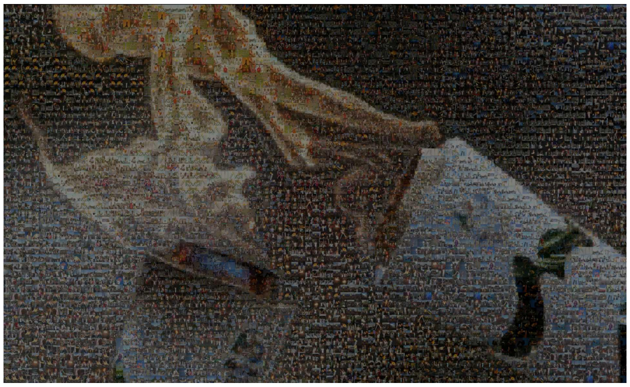

Figure 4. The mosaic

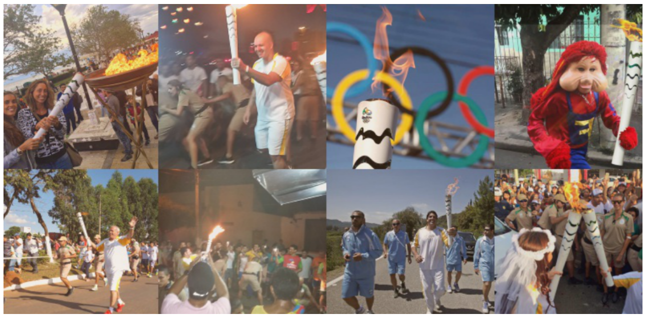

Figure 5. Tile images

The organization nature of the mosaic visualization is mainly aesthetic. Nevertheless, zooming and panning the mosaic allows the user to explore a wide variety of views, and to discover image details and surprises such as the spoof picture of *Fofão*, a Brazilian fictional character, carrying the torch.

For DH2017 poster session, we expect to present the results for another subject feature - the sporting disciplines - and visualisation technique - the *videosphere* - we are working on at the moment. In addition, we plan to discuss with participants some possible scenarios in which *Deep Learning* models could be applied to help image collections become more discoverable and expressive.

Originally funded by a startup grant from the National Endowment for the Humanities, *Le Dictionnaire Vivant de la Langue Française* (DVLF) is an experimental approach to dictionary compilation that aims to push the boundaries of what typical dictionaries offer. It is being developed as an interactive, community-oriented alternative to traditional methods of French lexicography, bringing together user-submitted definitions and definitions from standard French dictionaries (multiple editions of the *Dictionnaire de l'Académie Française, Dictionnaire de Littré...*), synonyms, pronunciation, as well as a wealth of information on word usage through the use of various computational methods. Our poster will show the DVLF's functionality, as well as demonstrate its originality.

Fundamentally, the most important aspect of the DVLF is that it aims to create an environment in which its user community rates, critiques, and adds to the collection's resources as it sees fit. As such, we have made a conscious effort to facilitate community engagement by allowing users to contribute to most sections of our website: definitions, usage examples, synonyms and antonyms. To date, users have added or submitted definitions/examples for hundreds of words, including **alexithymie**, **digiscopie**, **foucade**, and **nyctalope**. The new version of our site (released in January 2017) has been further enhanced to enable such engagement thanks to more visible links inviting users to contribute content, as well as a new responsive interface designed to work equally well on mobile devices and desktop computers.

In order to attract and engage the largest possible user community, the DVLF is entirely free and open source, and requires no registration. Internet users at large can access the site's resources and contribute material. The DVLF thus tries to adapt to changing word usage and incorporate neologisms so that users will be able to select the word senses and usage examples that they feel are most consistent with contemporary usage. In this manner, the DVLF mirrors the social and evolving nature of language, expanding upon the dictionary's traditionally normative role by giving French speakers and learners access to lexicographic tools so that they might interact with the evolving meaning of words and determine their own understanding of the language.

Over the last year, ARTFL has been working to develop and improve the DVLF. We noticed from statistics gathered from Google Analytics that our community of users was very diverse, accessing our website from Morocco, Tunisia, Canada, and many other francophone and non-francophone countries. This led us to focus a large part of our effort on diversifying content, including usage examples from a wider range of francophone sources in order to provide more coherent descriptions of emerging word usage from Francophone communities around the world, and therefore attract a larger global user base.

Over the course of this redevelopment effort, we decided to rewrite the entire codebase given the various reliability and performance issues we had experienced, switching from a Python-only infrastructure to a Go/Javascript environment. We have also worked to add additional contextual information to our content, starting with the most frequent collocates of any given word based a corpus of over 7,000 texts of French literature from the Middle-Ages to the late 20th century. Additionally, following the lead of recent work in computational linguistics and natural language processing, we also now provide the nearest neighbors based on the computation of word vectors using a word-embedding technique called Swivel. While we could have used alternative algorithms such as word2vec or Glove, we decided to use Swivel because it does not solely rely only on word co-occurrence to construct vectors. The benefit of Swivel's approach is that it can yield similar words that do not actually occur together in the corpus (see Shazeer et al, 2016), which we thought was a valuable approach given that our dictionaries span across multiple centuries. To generate this word vector model, we used the same 7,000 texts and then extracted the top 20 words for every headword in our dictionary index, which is now displayed on the new version of our site.

An Open, Reproducible Method for Teaching Text Analysis with R

Tassie Gniady
ctgniady@iu.edu
Indiana University, United States of America

Eric Wernert
ewernert@iu.edu
Indiana University, United States of America

Over the past year and a half, the Cyberinfrastructure for Digital Humanities (CyberDH) Group at Indiana University has been developing an open instructional workflow for text analysis that aims to build algorithmic understanding and basic coding skills before scaling up analyses (Gniady et al., 2017). We have chosen to bootstrap in R, a high level and high productivity language, with methods that are open, repeatable, and sustainable. The aim is to provide code templates that can be adapted, remixed, and scaled to fit a wide range of text analysis tasks. This poster presents our approach to teaching computational text analysis and a representative hypothetical case study in which two different users are able to start with the same corpus and adapt code to achieve very different end results in a way not currently possible with black box tools.

This paradigm is fundamentally different from that currently practiced by many in the digital humanities. Blackboxed tools with GUIs that hide computation are very popular for introducing new practitioners of text analysis in the digital humanities to basic algorithms and outputs. In 2012, AntConc was downloaded 120,000 times by users in 80 different countries (Anthony, 2014). Voyant 1.0 had 113 sites linking to it actively in 2012 (Sinclair and Rockwell, 2013) and the week Voyant 2.0 was released the server went down multiple times from excess traffic (@VoyantTools, 2016). However, one of its default corpora is the Shakespearean dramas, with speaker names and stage directions. ((Sinclair and Rockwell, 2016). The inclusion of speaker names skews all algorithms related to frequency counts of characters (e.g. word clouds), which a new user may not even think to take into account. Using AntConc's concordance tool with a Shakespearean corpora including speaker names gives an idea of when a character speaks **and** when a character is mentioned, but this conflation might not jump out at a new user. If anything, we suggest learning about algorithms **first** and then moving up to black-box tools when one has the means to critique them.

Having looked at popular "plug-and-play" tools for corpora visualization, it becomes evident that even simple visualizations can lead to inaccurate results if the user is not thinking through how a corpus is being processed to produce a result. We believe that if the user understands how the algorithm is generating visualizations, they can contribute more meaningfully to critiques of sophisticated algorithms when partnered with programmers or even go on to bootstrap themselves with awareness of their domain's particular caveats. Thus, we advocate teaching humanists the basics of coding to create **conversant programmers** similar to the methodology behind Matthew Jockers' *Text Analysis with R for Students of Literature*, but with a slightly slower ramp up. To this end we have a three-step process of introducing R: web-deployed Shiny apps, highly marked up RNotebooks, and lightly commented RScripts, both in "regular" and higher performance versions. All are available for download on Github (with associated sample data from Shakespeare and Twitter) (CyberDH Team, 2017). We hope that this simpler bootstrapping method that mixes code and explanation, pedagogy and self-driven inquiry, will be of use to those looking to onramp new practitioners who may go on to partner with programmers if needed or to remix available code to look at their own knowledge domain.

Information Infrastructure of Linked Data for Promoting Integrated Studies of Cultural and Research Resources

Makoto Goto
m-goto@rekihaku.ac.jp
National Museum of Japanese History, Japan

Ayako Shibutani
shibutani@rekihaku.ac.jp
National Museum of Japanese History, Japan

The National Museum of Japanese History (NMJH) is using digital technology to establishing its core research project, Constructing Integrated Studies of Cultural and Research Resources. This project offers unique insight into a variety of studies and Japanese historical resources through multidisciplinary collaboration with universities, museums, and other institutes. This paper introduces the initial application of Linked Data and IIIF (International Image Interoperability Framework).

Researchers working in the humanities and sciences with a focus on history need to collaborate with their peers in relevant fields to produce more diversity and substance in academic data. The plan for a new academic field is to construct a "research circulation model" that links academic studies and resource information through advanced cooperative studies. Although institute resources encompass a wide variety of materials, the poor quality of the current infrastructure has hampered researchers' access to original data and convenience in producing the primary evidence for research results.

The number of researchers specializing in the study of China, Korea, and Taiwan is increasing due to the rapid growth in the networks of historical resource information in these countries. In contrast, the number of their peers in Japan is decreasing, in part because of Japan's non-digitized and partially closed systems. This trend is particularly apparent in the younger generation, which is accustomed to using the internet. In our poster, we show an example of our collaborative studies with relevant local and international institutes. The name authorities and concept label authorities in the translation are related to the entities mentioned in the RDF (Resource Description Framework). In addition to preservation of data in the case of disaster, the poster presents our development of a support system in the affected areas and an advanced sharing infrastructure.

RDF is a de facto standard since it is easy to add and edit metadata. It also enables the addition of multiple metadata to a single data element. Giving each resource its own address produces a permanent link to permanent data. This is an advantage for any researcher or institute that uses the data as an academic resource. Linking one resource to multiple relevant resources enables one to find information resources consecutively, as well as resources followed by historical studies. Research results must refer to original resources. In addition to fundamental data, division of systems and RDF can share complex data and advanced applications. Our RDF-based prototype is currently being tested, but it can connect internal and external databases by linking their URLs.

To achieve the current results from resources in Japan, we also constructed an initial application of Linked Data and IIIF. It has five features. First, each resource has its one own address, which enables access to its resources from Google and other search engine results. Second, the application can access resources that follow another resource, such as a resource ☾an institute ☾another resource. Third, for smart device applications, spatial information is added to the resources. Fourth, the system and the data are separate. If a system is replaced or updated in the future, the data should remain usable. If an institute provides infrastructure data, other institutes or researchers can use the data to create applications. In doing so, the access path to the institute needs to be confirmed. Finally, RDF data are applied to the database.

We are currently implementing all the functions and testing for real data, including 150,000 triples of our museum collection, 20,000 triples of related de facto data, and approximately 500 IIIF images. We plan to integrate the data sets of other Japanese universities by August 2017, and the application will be fully launched at the beginning of 2018.

Here, we discuss links using Ukiyo-e of Japan. The Ukiyo-e material enables access to information concerning its holding institute as well as access to other collections. Its spatial information is also added to the resources. If, for example, Mt. Fuji is drawn on the Ukiyo-e, this application can show its spatial information. The application also connects to image data using IIIF (providing both Image API and Presentation API) from RDF data.

We are now constructing a system to connect information about the Ukiyo-e artist to information about his work. Some of these links include metadata, such as FOAF (Friend of a Friend) in the information about people, and other links use vocabulary defined by our project.

Complex Network Visualisation for the History of Interdisciplinarity: Mapping Research Funding in Switzerland

Martin Grandjean
martin.grandjean@unil.ch
University of Lausanne, Switzerland

Pierre Benz
pierre.benz@unil.ch
University of Lausanne, Switzerland

Thierry Rossier
thierry.rossier@unil.ch
University of Lausanne, Switzerland

Introduction

In Switzerland, the panorama of scientific research is deemed to be deeply affected by language barriers and strong local academic identities. Is this impression confirmed by data on research projects? What are the factors that best explain the structure of scientific collaborations over the last forty years? Do linguistic regions (Switzerland is divided into three principals) or local academic logics really have an impact onto the mapping of research collaborations and to what extend are they embedded in disciplinary, historical and generational logics?

We focus on the very large database of the Swiss National Science Foundation (SNSF), the principal research funding agency in Switzerland, which lists all the 62,000 projects funded between 1975 and 2015. While scientometric studies generally focus on measuring work – and financial – performance, we aim to raise awareness on pursuing a socio-history analyse of Swiss academic circles by crossing the SNSF data with a prosopographic database of all Swiss university professors in the twentieth century provided by the Swiss Elite Observatory (OBELIS). Beyond the interest for the history of science and universities, we explore the noteworthy technical challenge of a network analysis of nearly 88,000 researchers and more than a million of collaborations.

By combining those two databases, we measure the temporality and spatiality of academic collaborations, i.e. to define a way to deal with the volume of information in order to provide not only a global vision but also to enable a fine processing of personal trajectories.

Sources

The SNSF database has been placed under an Open Data licence in spring 2016. Called "P3" for "Projects, People, Publications", it contains detailed information on all the projects funded since 1975 (around 500 per year in the beginning, almost 3,000 per year today, see Fig.1), as well as the whole list of people involved in the projects. The database can sometimes be incomplete about the discipline and institutional affiliation of individuals, since it depends directly on the project submission interface where some fields may be left empty. Thus, this gap is partly offset by the junction with the Swiss professors database that provides systematic data on Swiss professors. Thus, the projects are classified according to a standard tree of scientific disciplines.

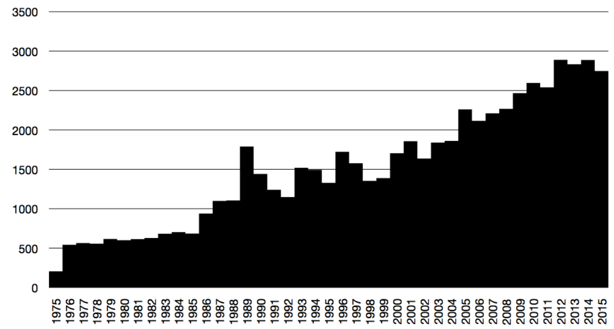

Figure 1. Evolution of the number of projects funded by SNF annually from 1975 to 2015.

Methodology

We are interested in the 2006-2015 period, ten years during which 25,000 projects involving 45,000 people produce a graph of more than 350,000 edges. On the one hand, this short periodization allows us to confront our assumptions to our data before analysing the full corpus. On the other hand, it helps to test the effectiveness of our tools and the interoperability of the two databases to prepare a complete and longitudinal modelling.

We therefore extracted a 2-mode network of people and projects from the database and then projected it into a 1-mode network of people only (the nature of the link being to be affiliated as collaborators to the same research project). If usually a relatively simple task, the transformation of a 2-mode graph into a 1-mode graph is here greatly complicated by the mass of information to process: when the graph matrix contains billions of positions, most softwares are reaching their limits. We will then divide the dataset into smaller units (here, transforming the network year after year helps make it bearable to a standard processor).

Analysis and Visualisation

The topography of the network obtained for 2006-2015 (Fig.2) is quite remarkable. The center of the network is not, as it is often, the densest region, which would have meant that a single discipline or field of study was likely to play a role of interface between others. Instead, we observe an almost circular distribution of individuals, recalling other "science maps" based on the organization of institutions of bibliometric analysis (Rafols et al. 2010). Data visualization, and in particular the representation of complex networks, is not an end in itself but a tool for questioning the structure of the dataset (Grandjean 2015). But while a further research will focus on more detailed indicators to qualify individual positions (in particular, centrality measures, as detailed by Koschützki et al. 2005 or Newman 2010), this first overview still shows that some groups of disciplines form very obvious clusters. This is the case of physics (right), medical sciences (bottom left) or earth sciences (top right). Others are sparsely connected or dispersed within other communities, as is particularly the case for disciplines like economics/business studies or chemistry, which seem to be more engaged in interdisciplinary collaborations or projects that include a limited number of employees (large experimental science projects partly explain the density of these groups). We also assume the structure of the network to differ among disciplinary specificities and temporality (Bourdieu, 2004; Gingras, 2012; Heilbron & Gingras, 2015). Are most connected disciplines also the most prestigious ones?

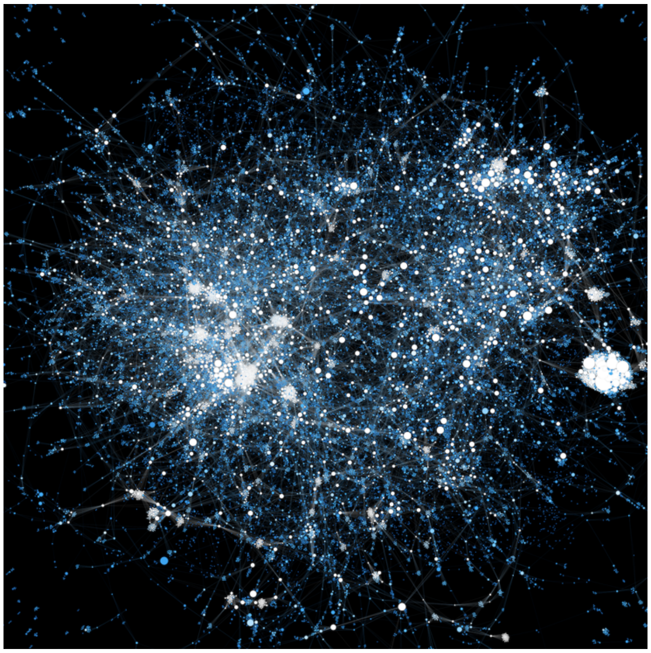

Figure 2. The core of the Swiss network of SNF scientific collaborations 2006-2016 (Grandjean 2016).

Perspectives

With the information contained in the list of projects, we see that it is also possible to assign individuals a disciplinary category extracted from the projects involving them. As it happens that a researcher is participating to projects labelled in different disciplines, this approach will lead to a reflexion on the measurement of interdisciplinarity within a comparative study between a selection of « open » and « closed » disciplines.

We will also see that it is possible to develop a multilevel analysis to compare the graph clustering to the many Swiss institutional and disciplinary « geographies », in order to historicize their development.

Mapping Prohibition: The Challenges of Digitally (Re)creating Historical Spaces

Hannah C. Griggs
hannahgriggs@gmail.com
Boston College

This poster will explore the challenges of creating digitized historical spaces as faced through the design and subsequent exhibition of the interactive, open-access map, *Prohibition Raids in New Orleans, 1919-1933*. During Prohibition, Federal agents (or 'Prohis') raided thousands of establishments throughout the city of New Orleans, arresting thousands more. Using data gleaned from *The Times-Picayune*, one of New Orleans's oldest newspapers, this map documents the proliferation of these raids through the 1920s into the early 1930s. Currently housed in The Museum of the American Cocktail in New Orleans, this exhibit is a collaboration between the Southern Food and Beverage Museum and my digital humanities project, Intemperance.org, an Omeka archive of cocktail culture in New Orleans. The goals and questions raised by this project will be presented in this poster. These include:

1. Summarizing the historical context of the project and considering the ways in which early 20th century New Orleans constructed and created spaces of leisure, as well as assessing the cultural importance of the bars, restaurants, residences, and other locales raided by Prohibition agents;
2. Exploring how to turn historical spaces into modern spaces in ways that are intuitive and accessible to diverse audiences and different publics;
3. Optimizing user experience for those viewers unfamiliar with the historical information presented and/or the digital platform(s) with which the exhibit was created;
4. Acknowledging the limitations of visualization and user experience of digitized historical spaces.

As a project rooted in Public History, the challenge of achieving the aforementioned goals lay in the digital platform. This poster will explain the exhibit's functionality goals and specific interactivity issues encountered during the exhibition's creation. This includes the ability to

- optionally read a description of the exhibit and summarized history;
- view details of each individual Prohibition raid;
- organize and view raids by year;
- filter by type of establishment raided;
- zoom in, zoom out, and view the page in full.

In order to achieve these goals, the exhibit was initially built in Neatline using the Starter Theme from Scholars' Lab, which works capably on any modern browser. Neatline advantageously allows users to explore the breadth of the historical archive by connecting Neatline points to Omeka items. When displayed on the Museum's multitouch tablet, however, issues of mobile compatibility and long loading times resulted in poor user experience. Ultimately, we had to modify the exhibition by changing the visualization platform to Tableau Public. Tableau not only circumvents the mobile compatibility issues found with Neatline, but it allows users to interactively filter historical data by year and raid type, a feature not currently possible in Neatline.

While both Neatline and Tableau are capable platforms to achieve these goals, each has its own advantages. With these specific goals in mind, this poster will furthermore compare and contrast the advantages and limitations of Neatline and Tableau Public as both mobile and desktop interfaces. This poster will furthermore highlight the exhibition's successful outcomes as well as the limitations of its interactivity. Much could be learned about visualization from the challenges faced in the creation of this exhibition.

Comparing Correspondences: Robert Southey and Willa Cather

Gabriel Hankins
ghankin@clemson.edu
Clemson University

Frank Elavsky
frankelavsky@gmail.com
Northwestern University

This poster presents recent work in the visualization of literary correspondence from the TCLLP (Twentieth-Century Literary Letters Project), focusing on the comparative visualization and analysis of digital editions of letters.

How might we begin to compare the collected correspondences of letter-writers? As archival letters are increasingly digitized, either by libraries and special collection or by the large-scale digital correspondence projects now emerging (e.g. the Electronic Enlightenment project, Early Modern Letters Online), we now have the opportunity to investigate authorial correspondence at larger scales. Beyond the usual use of correspondence to fill out the historical or biographical background of a writer, or to provide thematic and social points of linkage between writers, large collections of digital letters allow us to pose a range of new questions and problems: what does the social network of highly interconnected writers look like? What sorts of visual arguments and tools are appropriate to inquire into literary correspondence? How do the forces of class, gender, status, politics and profession manifest in a large correspondence? How do we read the gaps, cracks, elisions, and unseen limitations inherent both in our archival evidence and our digital tools? What are the large-scale shifts in epistolary culture over time, and how might we better understand those shifts in the correspondence of particular writers? To think through those questions more concretely, we visualized and compared the metadata of two well-curated digital correspondences from the early nineteenth and early twentieth century, the *Collected Letters of Robert Southey* and *A Calendar of the Letters of Willa Cather.*

We worked with the editors of these letters, and experts in TEI and RDF metadata transformation, to move the relationship implied by letter metadata – information about personal, political, geographical, and editorial networks of these very different writers – into visual representation. Our work forms part of an ongoing effort to bridge the gap between the Textual Encoding Initiative community, open linked data initiatives, and wider scholarly, library, and public audiences, as well as investigating important issues in data visualization as a hermeneutic activity.

This poster session presents our refined visualizations of these materials, and includes procedural as well as literary-critical findings: we will outline the process by which we move from TEI or less structured correspondence data into graph and network visualization; note some of interpretive and archival issues involved in that transformation; and display the refined visualizations comparing the political, personal, and literary networks of Southey and Cather. We hope to have an interactive conversation with attendees interested in network visualization, literary correspondence, Romanticism and modernism, open linked data, and the new TEI standards for correspondence data. The TCLLP is an open group of scholars interested in new approaches to twentieth-century literary correspondence, across linguistic, national, and disciplinary divides: we look forward to a discussion with Francophone scholars in particular.

Initial visualizations will be available on the project blog.

A Case Study of Automated Curation of Digital Archives

Fabiola Hanna
fhanna@ucsc.edu
UC Santa Cruz, United States of America

Access to digital archives has been well problematized in recent years. For example, should one have access to an archive by default or should one belong to a community in order to gain access to that knowledge,– such as with Mukurtu CMS which builds on knowledge heritage in indigenous groups (Christen 2007)? Another thread with regards to access and archives is the trend of dumping all the data, and claiming that because of this, the individual and/or the organization is somehow more transparent (as seen with various initiatives such as data.gov). But many have also shown that there is no raw data (Gitelman 2013). I propose to build on these two threads in order to argue that 1) paying attention to the medium and its parameters is important, and 2) that archives need to be sifted and curated in order for them to be properly accessible. I will illustrate both of these arguments with my project, *We Are History: A People’s History of Lebanon*, which is in its final stage of development and will have been released publicly before DH2017.

Digital Humanities (DH) projects are, in varying degrees, led by the desire to engage with a wider public. Some often include actions such as inviting participants to share their stories, images, audio clips, drawings, and videos. Many DH projects place these contributions in an audio or video database displayed in full on a webpage, not unlike oral history transcripts ending up in a dusty closet. To build on one of the most successful digital storytelling projects, it is useful to examine the Storycorps team, who have been collecting ordinary oral histories in video form and archiving them in full as a record of American history using booths and a mobile application. The Storycorps team knows very well that if it did not curate and edit together shorter versions, then few users would listen to the longer interviews in full, let alone several at a time.

Francis X Blouin and William G. Rosenberg trace the intersection of history and archives and found that Ranke, during the Enlightenment, conceptualized history as a scientific endeavor in that truth could be extracted from archives through rigorous methodologies. This led to the idea that documents could "speak for themselves" (Blouin, 24), as if simply making documents available, without providing context of any sort, would reveal their inner truth. This is one of many cases where the reading of documents is taken for granted. It also ignores the effect that archivists have on the collecting, saving, and indexing of documents. Influential archivists such as Terry Cooke, Richard Brown and Brian Brothman have brought about new attitudes to repositories with an acknowledgment of the effect that archivists have on documents (as quoted by Cox, 33). This relatively recent push in archival theory, therefore, points to the flaws in the claim that documents on their own can represent themselves: that would be ignoring all the various power relationships at play, as well as the medium itself in which the data is codified.

This is more directly seen in the tagging of videos and their categorization without additional interpretational work, such as in the Oral History Metadata Synchronizer (OHMS) tool developed at the Louie B. Nunn Center for Oral History University of Kentucky Libraries. This *will to not "add"* to these stories seems to come from the premise that these testimonies should "speak for themselves"; that no added interpretation is needed, even that any added interpretation distracts from the directness of the stories. But this often also means the medium and its effects on these stories are not carefully examined.

In pursuit of generating communal dialogue in the context of inability to have conversations about our contested history in Lebanon, I set out to build an Artificial Agent that would sift through an oral history video archive of testimonies of daily life with the task of figuring out common threads, sometimes confirming and sometimes contesting each other, and automatically editing many different versions of possible histories. This automatic montage machine addresses two problems in the Lebanese context: first, it circumvents the tiring accusation of being biased since a machine is now the moderator (presenting a multiplicity of stories might be the closest one can get to strategic objectivity) and second, it opens up the possibility of conversation by weaving various and often opposing perspectives in order to start imagining what our histories could look like. The project, which would reside online as well as in booths in public spaces across Lebanon, invites people to listen to an automated montage of oral histories and to then share their own stories and memories. Each newly contributed story is added to the archive, analyzed using new developments in computational corpus-based linguistics, automatic story generation, and social computing, and tagged with its transcript, which enables the interface to incorporate newly added video interviews into the pool concerning the event discussed

Mapping Pliny's Social Network: A Case Study in Digital Prosopography

Benjamin Hicks
bhicks@princeton.edu
Princeton University, United States of America

Introduction

This proposed short paper examines the progress and some preliminary observations of a practical attempt to apply digital humanities methods to the letters of a second century Roman aristocrat Pliny the Younger. The preliminary results of this study are available at the Pliny Project site. Its aim is to present a case study of how an initial research idea can be expanded to connect with larger digital humanities work in a particular field.

These letters, written in the early second century CE, are a treasure trove of social and literary information about the Roman elite during the period in which Roman territorial control reached its apex. As one of the most extensive collections of letters from the ancient world, as well as one of the most thoroughly explored, they are a rich data set on which to draw. They are paralleled by only a handful of similar letter sets from the Roman world, such as the letters of Marcus Tulilus Cicero or the four century orator Libanius.

In a broader context, Classics has been a frequent and early adopter of digital humanities methods (see *Online Coins of the Roman Empire*, the literary comparative tool *Tesserae*, and the venerable *Perseus Digital Library).* The field has also produced some initial attempts to bridge various "people indices" into a standard prosopography (i.e. the Standards for Networking Ancient Prosopographies, hereafter SNAP). Pliny's correspondents have been integrated into such resources, but they are either often limited to major university research collections or so unwieldy as to make consultation difficult. Examples of this tension include the standard tool for the prosopography of the Roman Empire, the *Prosopographia Imperii Romani*, 2nd edition (de Gruyter: 1933-2015) (= *PIR*^{2}), which has reached a massive eight parts with numerous fascicles. Only the index is widely available online. Likewise the most recent work on Pliny's names, Anthony Birley's *Onomasticon to the Younger Pliny (*Birley, 2012*)*, exists as a traditional monograph, albeit with a searchable PDF.

Such resources, though tremendously important to scholars specializing in the field, often constrain access for the broader academic community. Moreover, the rich information they provide is not structured in a way for easy search and access.

The research project on which this paper draws developed from a November 2015 – January 2016 affiliated fellowship at the American Academy in Rome, which gave me access to the prosopographic material in a single, well-organized location. Its primary objective was, and is, to create a comprehensive resource for Pliny's social network with an emphasis on the social class of his correspondents. My initial inquiries centered on compiling a list of Pliny's correspondents and attempting to identify them as best possible. The conventions of Roman naming, which resulted in many similar names within family groups, renders this difficult. The use of only a single name (compared to the somewhat standard use of two names) in one of the surviving manuscripts of the letters further complicates the task. Even if a family and identity of an individual is known, his or her social standing may not be clear. The Roman distinctions between a common citizen, the middling administrators of the equestrian class, and the upper rungs of the senatorial class were very sharp to them—so sharp they often saw no need to clarify who was of what class for posterity.

This made data modeling and cleaning a significant challenge, for which I employed exploratory tools such as SocNetV and more recently Cytoscape, for exploratory visualization. (Note: this issue of authorial ambiguity is not new to DH and letters. It has been frequently confronted by projects such as Stanford's *Mapping the Republic of Letters*). Some preliminary results are available through Pliny Project (see above), but they have been revealing both in terms of confirming known associations and providing new clarity into the possible editorial methods Pliny used in selecting his letters, which were curated for publication within his lifetime.

In order to construct a data set for such an analysis, I attempted to model a degree of closeness of connection by assigning a weight based on the number of times Pliny either mentioned someone in a letter or wrote to them to a reciprocal connection. This was saved in GraphML format to construct a diagram of centrality with shading of points to indicate the social class of Pliny's correspondents.

My talk will, in addition to discussing the above methodology in greater detail, center on two examples of preliminary results from this research, and then turn to future plans for the project. First, the set of social acquaintances that have often been associated with as what is informally called "Pliny Country"—near his home near modern-day Como, Italy—and the set associated with the city of Tifernum, both appear clearly in the social network map as a set of closer intimates, largely from the same equestrian class of which Pliny's family originated (the original formulation comes from the work of the eminent historian Ronald Syme, see Syme, 1991, for his collected works and the exploration of some of Pliny's connections of Tifernum in Champlin, 2001).

This gives preliminary confirmation that the methodology of simple weighting based on mentions as some approximation of closeness can be used in analyzing his social network.

A secondary observation is a series of correspondents to whom Pliny writes roughly two to three letters in the second to outer circle of his acquaintances. Some of these individuals are men who had held the consulship, the highest office to which a Roman not of the imperial family could aspire and all were of the senatorial class. Pliny rose to that same class from middling origins during his career, thanks to the patronage of his uncle and adoptive father. That there is a cluster of these letters with a remarkably similar number speaks to an editorial hand at work in their selection. While at this point identifying a motivation is primarily speculative, at the least we can say that it reveals a trend not previously identified and demonstrates an editorial concern for cultivating Pliny's prestige by association.

In addition to the specific application of this data to my own research, the longer term goals of this project are to provide this same dataset, edited and curated, to the broader scholarly community. I have currently published a simple database interface that allows users to search for Pliny's correspondents and note which letters are written to them. While this may seem on the surface a straightforward question, by integrating current scholarship and attempting to identify correspondents fully, it presents new and easier access for scholars, regardless of institutional affiliation.

Nevertheless, the initial search functions, which allow a name search and a tentative search by social class, are not sufficient to realize the goals of the project. My current development work is focused on transitioning the database to using Django's web application functionality and object database modeling to allow for the relationships noted in my social network analysis to be available and searchable. This transition to a standard platform will also lead to a web application that can be cloned from a tool such as GitHub and used by DH scholars to build or innovate using my dataset. It also acknowledges the need to connect this new structuring of the prosopographic corpus for Pliny to the broader initiatives to create people indices by including links to *PIR*^{2} search masks and SNAP.

Such an approach takes the traditional field of Plinian prosopography and attempts to open it to a wider scholarly audience. It also emphasizes the importance of exploratory visualization techniques in examining datasets for novel connections. This discussion will offer the audience an opportunity to consider how a project focusing on a specific area of research can connect with larger scholarly endeavors in DH.

POSTagging and Semantic Dictionary Creation for Hittite Cuneiform

Timo Homburg
timo.homburg@hs-mainz.de
Mainz University of Applied Sciences, Germany

Presentation Topic and State of the Art

On our poster, we want to present ongoing work to create an automatic natural language processing tool for Hittite cuneiform. Hittite cuneiform texts are, to this day, manually transcribed by the respective experts and then published in a transliteration format (commonly ATF). Pictures of the original cuneiform tablet may be provided and more rarely cuneiform representations in Unicode are present. Due to recent advancements in the field (such as Cuneify) an automatic translation of many Hittite cuneiform transliterations to their respective cuneiform representation is possible.

Research Contributions

We build upon this work by creating tools that aim to automatically translate Hittite cuneiform texts to English from either a Unicode cuneiform representation or their transliteration representation.

POSTagger

We have created a morphological analyzer to detect nouns, verbs, several kinds of pronouns, their respective declinations and appendices as well as structural particles. On a sample set of annotated Hittite texts from different epochs in cuneiform and transliteration representation, we have evaluated the morphological analyzer, its advantages, problems and possible solutions and intend to present the results as well as some POSTagging examples in section one of our poster.

Dictionary Creation

Dictionaries for Hittite cuneiform exist in often non-machine readable formats and without a connection to Semantic Web concepts. We intend to change this situation by parsing digitally available nonsemantic dictionaries and using matching algorithms to find concepts of the English translations of such dictionaries in the Semantic Web e.g. DBPedia or Wikidata. Dictionaries of this kind are stored using the Lexical Model for Ontologies (Lemon). In addition to freely available dictionaries we intend to use expert resources developed by the academy of sciences in Mainz/Germany to verify and extend our generated dictionaries. We intend to present the dictionary creation process, statistics about the content of generated dictionaries and their impact in section two of our poster.

Machine Translation

Using the newly created dictionaries as well as the POSTagging information we intend to test several automated machine translation approaches of which we will outline the process and possible approaches in poster section three.

Contributions for the Communities

With our approaches, we intend to contribute to the archaeological community in Germany by analysing Hittite cuneiform tablets. Together with work from the University of Heidelberg on image recognition of cuneiform tablets, we want to focus on creating a natural language processing pipeline from scanning cuneiform tablets to an available translation in English.

Spatial-temporal Variation based Innovation History Visualization: A Case Study of the Liquid Crystal Institute at Kent State University

Kent State University, United States of America

Innovation began taking root as a term associated with science and industry in the nineteenth century, matching the forward march of the Industrial Revolution, although the language of that period focused more strongly on the invention, particularly technical invention (Green, 2013). Nowadays, innovation is defined simply as a "new idea, device, or method" (Wikipedia). In the Big Data era, innovation history research not only shows the raw data but also demonstrates and reveals the deep relationships of data and how the innovation was generated.

This poster mainly describes an innovation history analysis system, integrating and visualizing multi-source and isomerism data in a static and dynamic representation manner, considering spatial-temporal factors. A case study of the Liquid Crystal Institute (LCI) at Kent State University is presented. Liquid Crystal Institute (LCI) was founded in 1965 by Glenn H. Brown, a chemistry professor at Kent State University. The birthplace of liquid crystal displays (LCD), the LCI is the world's first research center focused on the basic and applied science of liquid crystals. The dramatic rise of the liquid crystal display (LCD) industry through the subsequent 40 years has fundamentally changed our modern life.

As shown in Figure 1, to research the innovation history of LCI, there are varieties of data sources in the forms of audio, video, digitalized images, text from the website, annual reports from 1965-2013, interviews with key researchers in LCI, booklets from LCI's 50 year anniversary that covers significant scientists and important events, as well as biennial International Liquid Crystal Conference (ILCC) materials about the largest academic meeting in the field of liquid crystals that was started by the LCI founding director Glenn H. Brown in 1965. At the data processing level, data searching rules related to the publications, grants, and patents are appointed. For text, text mining tools, such as Open CALAIS and Cogito Intelligence API, are used to extract people, locations, and event information from annual reports, booklets etc. After the initial processing of raw data, data are then imported into our system, including publications records, grants, patents, inventions, researchers (such as research staff, post-doctoral fellows, visiting scholars, etc.), special events, spin-offs, and conferences.

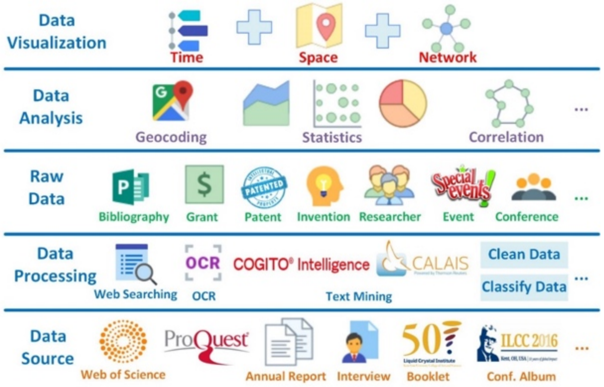

Figure 1. Structure of LCI innovation system

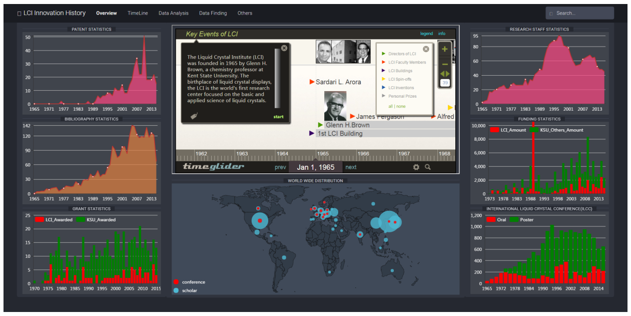
As argued by Robert E. Williams (Williams, 1987), location can be the critical link to integrating data from various sources and with various attributes of a place. Using locations as the key link, any location-related description, from the formal coordinates of places to the informal abstraction of places, can be understood by using GIS and various types of Big Data. Thus, the system geocoded the data which has location information. Besides traditional data statistics methods, with geo-located data, spatial statistics algorithms can also be imported to our system to find the spatial correlation of data.

Data visualizations are used to demonstrate the worldwide impact of LCI related scientists, technologies, and events. Unlike other tools, such as the "Historical Data Exploration Tool" (Škvrňák and Mertel, 2016), this system will statically visualize time, space and network variables, whilst also considering the dynamic network changes in each period. Furthermore, spatial-temporal analysis algorithms will be imported to display the spatial and temporal pattern of LCI development. Figure 2 shows visualization results based on the gathered and processed data. It is developed by modern web technologies (html5 canvas, javascript, d3 – see Bostock et al, 2011; timeglider). In the center top, there's a timeline integrating important faculty members, inventions, personal prizes, spin-offs, and other great events since 1965.

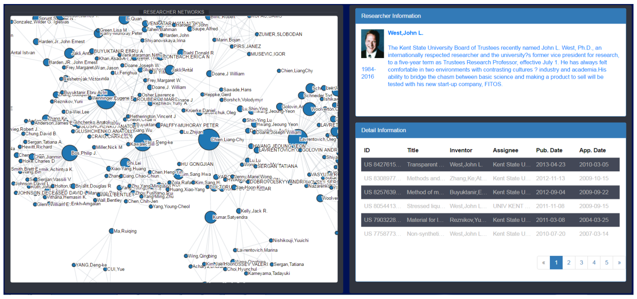


The Liquid Crystal Institute (LCI) was founded in 1965 by Glenn H. Brown, a chemistry professor at Kent State University. The birthplace of liquid crystal displays, the LCI is the world's first research center focused on the basic and applied science of liquid crystals.

Figure 2. Main interface of innovation history research system

Scientific collaboration is a complex social phenomenon in a search that has been systematically studied since the 1960s (Noldus and Van Mieghem, 2015). One of the goals of developing this system is to find out how the LCI can be so successful in liquid crystal field research and development.

From the view of research collaborations, it may demonstrate the answers. Thus, the system processes the data related to papers, patents and grants, and visualize the collaboration networks shown in Fig. 3. On the left of the figure, it demonstrates the networks, in which each node indicates an author (inventor or grant recipient) and each link indicates the collaboration. On the right, it presents the detailed information of researcher when clicking on the node.



West,John L.

1984-2016

The Kent State University Board of Trustees recently named John L. West, Ph.D., an internationally respected researcher and the university?s former vice president for research, to a five-year term as Trustees Research Professor, effective July 1. He has always felt comfortable in two environments with contrasting cultures ? industry and academia.His ability to bridge the chasm between basic science and making a product to sell will be tested with his new start-up company, FITOS.

Add Slander and Stir: Reprinting of Anti-Labor Stories in Early-Twentieth-Century American Newspapers

Vilja Hulden
vilja.hulden@colorado.edu
University of Colorado-Boulder
United States of America

In the opening years of the twentieth century, the National Association of Manufacturers (NAM), an organization of businessmen vehemently opposed to labor unions, spearheaded a multifrontal and multi-industry campaign aiming to stop the rapid growth of labor unions. The NAM itself envisioned publicity and propaganda – or a "campaign of education," as the NAM liked to call it – as a key aspect of this campaign. Newspapers, in turn, were to play a crucial role in the campaign. As the head of the publicity agency the NAM hired said, the "infantry" of the whole campaign consisted of "the constant repetition of small paragraphs or short articles throughout the newspapers of the country.”

The publicity bureau promised that getting this “infantry” into the field was going to be smooth sailing, claiming that "it is easily possible to bring together the vast majority of papers all over the country in a kind of syndicate form." With this, the bureau referred to syndication of the type now familiar to us, but also something specific to the early 20th century: boilerplate and readyprint. Because typesetting was still very expensive, large numbers of small country newspapers got part of their paper either preprinted (readyprint) or as boilerplate (stories that were already typeset and could be directly printed).

Archival sources show that the NAM, besides hiring a publicity bureau to badmouth labor unions, also created "newsworthy" events that it hoped to get into the press without direct payment: these included, for example, staged anti-union parades and Astroturf anti-union worker organizations. What we do not know with much certainty, however, is to what extent these efforts were successful.

This poster reports on a preliminary investigation into the extent to which stories reproducing the language or viewpoint of anti-labor organized employers – a language that is quite recognizable if one is familiar with it – were reprinted in early-twentieth-century American newspapers. It draws on the Chronicling America database of newspapers and makes use of a reprint detection algorithm developed for the Viral Texts project. Eventually the aim is to create as comprehensive an account of such reprinted texts as allowed by the geographical and other limitations of the Chronicling America collection.

Sources and methodology

The dataset used in this investigation consists of the articles (or rather, pages) published between 1897 through 1908 that matched the query (worker OR workers OR workmen OR workman) AND (union) in the Chronicling America collection. The time period selected reflects the years surrounding the launching and high point of the employer open shop campaign, including the NAM's hiring of the publicity bureau noted above.

The identification of reprints is performed using the passim tool developed by David Smith for the Viral Texts project with the default settings (which were developed on Chronicling America material). The results are formatted into an HTML form for easier manual checking; as the algorithm inevitably identifies irrelevant reprints, the most laborious stage is the culling of the set of identified repeated passages.

The early-twentieth-century employer anti-union campaign had a recognizable vocabulary and set of themes, and it is the author's expertise, acquired developed through research on these employer campaigns, that is the main "method" for recognizing stories potentially put out by employers.

Results

As of current writing, I have processed 1906, 1907, and, partly, 1908. For these years I have run the passim algorithm and manually examined the resulting identified reprinted clusters, which has turned out to be even more laborious than anticipated.

On the whole, I expected to see more stories clearly planted by NAM or its allies in readyprint or boilerplate. There are a number of candidates, but these are both less conclusive and have fewer reprints than I anticipated. There are, however, a few very widely reprinted clearly paid-for advertisements excoriating unions.

In some ways, the partly "negative" results in themselves are rather interesting (they seem not to be at least entirely due to any failings of the algorithm – widely printed items like speeches by the President are also prominent among the reprints). They seem to indicate that despite publicity bureaus' interest in claiming that material could be easily and discreetly planted, the task of shaping public opinion was more challenging that the NAM perhaps anticipated. The very fact that readyprint and boilerplate had to be palatable to a broad cross-section of papers, in an environment where there still were many labor or pro-worker papers, meant that "syndicated" material needed to be bland and apolitical to sell. Perhaps the democratic role of the press was better protected than expected?

A Seat At "La Tawola"

Michael Iannozzi
miannozz@uwo.ca
Western University, Canada

Introduction

In Italian, il tavolo means 'the table', but la tavola, the feminine form, is 'the sense of family felt around the dinner table'. My grandparents taught me the meaning of la tavola first-hand; they emigrated from Italy in 1959. Through my research, I document the Italian dialect of immigrants in Sarnia, Ontario, Canada. Through community collaboration, we work to preserve their stories.

What?

Heritage languages are those brought by immigrants to a new place, and now spoken as a minority language by that community (Fishman, 2001). There are two parts of this research: to record the histories of this community in their native Italian dialect; and second, to create a permanent and public digital archive to preserve this Heritage Language.
The research question is: What is the best approach to create a community-university partnership that will benefit both the heritage and academic communities?

Why?

From 1950-1969, at Halifax's Pier 21, 20,000-30,000 Italians arrived each year in search of a better life (pier21.ca). Today, 1.4 million Canadians identify with an Italian heritage (StatsCan, 2013). Almost all Canadians have a 'hyphenated' identity: Italian-, Dutch-, French-, etc. By collaborating with the university and heritage community to build a digital archive, I will establish an interdisciplinary means to preserve Heritage Languages and the histories of Heritage Communities throughout Canada.

Where?

I have signed a two-year partnership with the Archives of Sarnia and Lambton County to create an online archive. Through this project, I digitized and uploaded hundreds of recordings, videos, images, and documents recently collected by myself, and by Caroline Di Cocco since the 1980s. Caroline is a local community historian who has contributed what she collected over the past 40 years. We will formally present the archive to Sarnia's Italian community in June, 2017. This serves as a starting point showing the project's feasibility.

I have been given permission by Western University's Libraries to host this archive, permanently, at the University. The *Western Archive of Dialects and Languages* (WADL) is available for other language projects, and my Italian research is the initial project to be hosted there (www.ir.lib.uwo.ca/wadl). Western University is only an hour from Sarnia, which allows me to remain an active member of Sarnia's Italian community, and to keep the digital archive local.

How?

With the support of Western Libraries and Sarnia's Italian community, the archive is being created through my coordination of the community and academia. Through my work with Lambton County Archives: I code the website; use *Dublin Core* standards for metadata (Kunze et al., 1998); and digitize materials. I use Omeka software for the framework.

The archive is made up of many photographs, documents, and videos. I have collected and digitized just under 500 photographs so far. It is also made up of documents: digitized copies of boat tickets to cross to Canada, citizenship papers, letters, (delicious) recipes, and other ephemera of their Italian and Canadian experiences. I have just under 200 documents so far.

I am currently recording interviews with Ciociaria dialect speakers, using sociolinguistic techniques to collect life histories. I also have 47 interviews I've digitized that were conducted in the 1980s by Caroline di Cocco.

Conclusion

WADL ensures that the community directly benefits from sharing their stories, materials, and time with the researcher. The information they share is returned in a permanent, secure, and digital way. This ensures that future generations will be able to access their heritage and history.

The goal of this research is to show the importance of heritage—a significant part of the Canadian identity. My work will produce a collaborative partnership between Western University and Sarnia's Italian community. This framework can be applied to preserve and promote other communities across Canada.

In summary, the stories, culture, and language of this community cannot wait any longer to be recorded and digitized. There is an urgency as Sarnia's original Italian community is reaching an advanced age. Now is the time to create an online presence: both for academics and for the public. There are research opportunities in this data, from a great number of disciplines. The community and broader public is interested in hearing these stories, seeing these photos, and cooking some of the recipes.

I study how Sarnia's Ciociaria pronounce "la tawola", and ensure the survival of what they mean when they say it.

Points, Lines, Polygons, and Pixels: A Framework for Teaching & Learning Humanities through Visualization

Hannah Jacobs
hannah.jacobs@duke.edu
Duke University, United States of America

Introduction

Points, lines, polygons, and pixels, the primary elements of digital visualization, can be arranged and rearranged to present infinite interpretations of space, time, objects, or patterns. Visualization offers a significant opportunity for humanities students to develop digital visual literacies through exploratory making, analysis, and storytelling. Yet incorporating digital visualization components into teaching depends upon instructors' course content and access to expertise, time, and tools. A scalable, replicable approach is needed to support visualization pedagogies that can be implemented in diverse educational environments. In this poster, I propose a framework for designing and implementing visualization projects within existing courses, drawing on my instructional experience in the Wired! Lab at Duke University.

Background

The rising prevalence of visual media in global society points to an increasing need to cultivate digital visual literacies in humanities classrooms. Susan Brown has noted this "shift from textuality to visuality," calling for more "active engagement with new technologies rather than passive consumption." Through this engagement, students may learn to create scholarly visualizations and can become thoughtful critics of the visual media with which they interact in everyday life.

My role with the Wired! Lab involves working with instructors to design and implement such visualization projects. These projects have involved a variety of methods, including architectural modeling, mapping, digital exhibit curation, and information visualization. (see the list of recent student projects) Through these collaborations, our instructional teams have recognized a need for both scalability and replicability in assignment design and implementation. Accordingly, I have begun to approach to project design with an eye toward creating instructional templates that can be applied to multiple topics and course levels. This strategy has been echoed by Aaron Mauro, who calls for an emphasis in undergraduate digital humanities on "iterability, openness, and extensibility" (Mauro, 2016). Assignments must be made flexible, or responsive, to varying constraints in instructors' and students' access to resources both in and beyond the Wired! Lab. In response to this need for project plans that can be adjusted to a variety of contexts, I am developing a framework for iterative course project design.

Framework

This proposed framework presents a decision-making process that enables instructors to shape project ideas into assignments suitable for their multiple contexts. The framework seeks to match digital methods and resources with pedagogical goals, course content, and visualization concepts by guiding instructors through an iterative planning process:

Instructors are first asked to devise a research question, based on their course goals and content, that will drive the assignment. Next they develop a list of possible source materials and ascertain whether these materials are accessible to students. If materials are not available, instructors revise their question around available sources. These sources are then examined with the aim of identifying types of information: is it quantitative, qualitative, or both? How might this information be further classified—spatially, temporally, statistically, categorically? Of these data types, which provide evidence needed to answer the research question? (If this process reveals that the data are not useful, instructors should return to their question and list of sources to reevaluate.)

Based on the process so far, instructors consider first how the visualization will be used: will it be a tool for exploring information and analysis? Or will its present an interpretive visual narrative? Second, will the visualization(s) be static or dynamic? Third, instructors consider which visualization type(s) might provide the best mode(s) of representation: scientific, informational, conceptual, spatial, temporal? Within these types, instructors begin to identify specific methods: mapping or 3D modeling, data visualization or visual narrative, for example. Then another moment of reflection: does the chosen method fit the research question, course goals, and visualization purpose? If not, instructors may reconsider their method in conjunction with these decisions.

Finally, instructors begin exploring possible tools as they examine their design thus far in comparison to both students' expected skill level and institutional resources: access to expertise (theirs or someone else's), additional time before and during the course, and tools (hardware, software, internet).

Resulting visualization projects may require few or many interventions in the course structure and content. They may rely on a combination of visualization techniques. They may be applied in multiple course iterations. Overall, they should engage the research question while advancing digital visual literacies.

Conclusion

Visualization is a powerful tool for communication that can be investigated across humanities disciplines. It can be employed to develop students' critical abilities to represent humanities research in a multitude of ways. This proposed framework addresses the challenges instructors face when implementing visualization in classrooms: from matching content to method, to identifying appropriate tools, to designing for scalability across one or more course settings.

On the Impact of the Merseburg Incantations

Stefan Jänicke
stjaenicke@informatik.uni-leipzig.de
Leipzig University, Germany

While searching for medieval manuscripts suitable for the "Monumenta Germaniae Historica" (a collection of German historical sources) in 1841, Georg Waitz visited the library of the Merseburg Cathedral (Jankofsky, 2013). Rather coincidentally, he found a page with two magic spells in a theological composite manuscript: the Merseburg Incantations (see Fig. 1). Realizing the importance of his discovery, he asked Jacob Grimm to analyze and evaluate the text. The first Merseburg Incantation is a *blessing of release* telling about "Idisen" (female dieties) freeing either themselves or captured warriors from chains. The second Merseburg Incantation is a *healing spell* to cure a dislocated horse foot. The spells in Old High German were written down in the 10th century, but their origin is still unclear, maybe several hundred years earlier. The first time publicly presented at the Royal Prussian Academy of Sciences in Berlin, Jacob Grimm denoted the value of the Merseburg Incantations by calling them a gem, and nothing from the most popular libraries would have a similar value (Grimm, 1842).

Figure 1: Merseburg Incantations manuscript

A number of works interpret content, meaning and origin of the Merseburg Incantations (e.g., Schumacher, 2000, Beck, 2003, and Schmitt, 2011). In contrast to these rather profound analyses and interpretations of the Merseburg Incantations, our project aims at examining their global impact. We therefore design a platform that brings together various types of sources––tagged with citation year, source type, reference purpose––citing the Merseburg Incantations. Some examples are listed below.

Sources citing the first Merseburg Incantation:

- "Die Südharzreise", Frank Fischer, 2010, travelog
- "Mara und der Feuerbringer, Band 03: Götterdämmerung", Tommy Krappweis, 2012, novel
- "Angelina Jolie - The Lightning Star", C. Duthel, 2012, biography
- "Seelenriss: Depression und Leistungsdruck", Ines Geipel, 2013, psychology

- "Die Schwarzen Musketiere - Das Buch der Nacht", Oliver Pötzsch, 2015, novel
- "Charlemagne", Johannes Fried and Peter Lewis, 2016, historiography

Sources citing the second Merseburg Incantation:

- "The Key to Music's Genetics: Why Music is Part of Being Human", Christian Lehmann, 2014, musicology (example for healing through singing)
- "Ring of the Nibelungs", German dubbing, 2004, TV Movie (entertainment)
- "Die Leute vom Domplatz", Episode 1, 1979, German TV Series (entertainment)
- "To Ride a White Horse", Pamela Ford, 2015, novel
- "Healing Symbols in Psychotherapy: A Ritual Approach", Erik D. Goodwyn, 2016, psychology
- "Harzer Pferdezucht im Spiegel der Geschichte", Bernd Sternal, 2015, horse breeding
- "Metallische Implantate in der Knochenchirurgie", Erich Frank and Herbert Zitter, 1971, medicine (bone surgery)
- "Norse Magical and Herbal Healing", Ben Waggoner, 2011, medicine (medieval medical text collection)

Sources citing both Merseburg Incantations:

- "Handbuch der germanischen Philologie", Friedrich Stroh, 1985, philology
- "Götter und Kulte der Germanen", Rudolf Simek, 2004, mythology
- A number of music songs, e.g., performed by In Extremo, Saltatio Mortis, Corvus Corax or Tibetréa, music (entertainment)
- Merseburg Incantations Geocache, since 2004, geocaching puzzle

Although this is only a tiny snapshot of sources referring to the Merseburg Incantations, some tendencies are already visible. Whereas both Merseburg Incantations are cited in a number of books on mythology and philology (only one of each category is listed above), there are also some differences dependent on the spell contents, e.g., historiography for the first spell, and medicine for the second. Next to these reasonable source types, there are also unexpected findings like programming for the first spell, and horse breeding for the second. Both Merseburg Incantations are also often used for entertainment purposes in the form of novels, in music songs, or in movies. Also an interesting finding is a Geocaching puzzle guiding to a Geocache that is hidden in Merseburg.

The project is designed as a two-stage student internship, where Masters students of the humanities and computer science collaboratively work together in order to gain experiences for future digital humanities projects. The first step is data acquisition, which is performed by humanities students. Although web search engines, e.g., platforms with digitized contents such as Google Books or Internet Archive for textual sources, are the entry points for data acquisition, data extraction and structuring is done manually to ensure high data quality and to capture the purpose of the reference as precisely as possible. For example, we extract detailed information about the context in which a spell is cited, e.g., in the biography about Angelina Jolie the first Merseburg Incantation is referenced in a movie description of Beowulf, in which Angelina Jolie partook as a supporting actress. The second step of our project is the development of an interactive visualization system to support the dynamic exploration of the data collection. Therefore, computer science students design several visual interfaces that summarize different metadata information (e.g., a timeline to visualize the temporal impact, or a tag cloud to illustrate source types). One of the major functions of the system is a comparative view on the different contexts in which the Merseburg Incantations are cited together and each of them individually. Although the data is collected in a time limited project, the system is designed as a web-based crowdsourcing platform, so that the database can be extended after the project. A specific feature of the system is genericity, which makes it applicable to other texts in question. For example, creating a collection of citations of the Trierer Zaubersprüche or the Hildebrandslied will be possible, also in the form of a comparative analysis.

An interpretive approach using our proposed system will be complicated due to the fact that the collection contains serious scholarly as well as artistical references, and it is not possible to draw a clear line between such groups. Also, we consider each citation as equally relevant, which might not evolve a convincing representation of impact. While it is furthermore not possible to collect “all” citations, supporting hypotheses generation after distant reading analyses is not the prior purpose of our system. Our aim is rather to establish a starting point for exploring the far-reaching significance of the Merseburg Incantations––one of the most important written samples of German language, even the oldest and only known preserved text about Germanic Paganism in Old High German. With our project, we want to fulfill the responsibility to sustainably highlight this uniqueness.

Topic modeling, a method for the semantic analysis of large text collections, has been in the focus of interest in digital literary studies during the recent years. The method uses probabilistic procedures to generate probability distributions for words out of a collection of texts, sorting many single word distributions into distinct semantic groups called ‘topics’. These topics constitute groups of semantically related words, and the contribution of each topic to the composition of each text can be quantified mathematically (Blei 2012, Steyvers und Griffiths 2006). In digital literary studies, topic models can be interesting in themselves. For example their dynamic development either during the plot of single literary texts or over multiple texts in a stage of literary history can be analyzed (Jockers 2013, Blevins 2012, Rhody 2012, Schöch to appear), though comparing literary themes and the probabilistic concept of ‘topics’ described here is obviously not unproblematic. And topic models can also be interesting features for classifying or clustering texts (Blei 2012).

There are currently two state-of-the-art implementations of the relevant algorithms: ‘Mallet’ (McCallum 2002) and

'Gensim' (Rehurek 2010). But usually more is required than simply running a topic modeling algorithm (Fig. 1):

- Longer texts like novels need to be split into smaller parts (e.g. paragraphs, scenes, or a fixed amount of characters or words).
- NLP based preprocessing is necessary
- To achieve optimal results, texts must be reduced to content words, either by filtering out function words with stopword lists, or by using a part-of-speech tagger to exclude unwanted word classes.
- Similarly, lemmatization and elimination of proper names can be useful.
- After the topics have been generated, results are usually visualized based on the relevant metadata.
- Results need to be evaluated with regard to internal or external criteria rather than just being left to interpretation.

The aim of our work is to provide digital literary scholars with a consistent, extensive and well documented programming library that allows them to do the necessary preprocessing, to generate topic models relying on the existing implementations, and to visualize and evaluate results within a single convenient scripting environment. We want to empower users with little or no previous experience and programming skills to create custom workflows mostly using predefined functions within a familiar environment (see the current stage of development on Github). Hereby, we want to lower the access threshold to topic modeling as a method, facilitating researchers in spending time experimenting with topic modeling and understanding how it generates results, rather than spending it for acquiring advanced technical skills before being able to try topic modeling at all.

The library will be developed for the programming language 'Python' that is well suited for NLP and data analysis tasks, and popular among digital literary scholars already. In addition, development can be partially based on functions from, and experiences made with a previous Python-based implementation of a topic modeling workflow developed by Christof Schöch et al., that can be regarded as a proof of concept.

A convenient tool for NLP analysis during preprocessing does exist in the DARIAH-DKPro-Wrapper (DDW) that covers a wide range of NLP tasks for many different languages and generates annotations in a Python-Pandas compatible format easily usable within our library.

Evaluating the results of topic modeling is not a trivial task but has proven to be rather challenging (Wallach et al. 2009, Chang et al. 2009). In order to evaluate topics we will provide functions for intrinsic evaluations, for example perplexity, and external evaluations, for example path length in a resource like wordnet. We will also support task based evaluation where topics are used for a classification task and evaluated on the basis of the results.

For the visualization of the results we can build on the tmw library mentioned above and provide plots of topics over time (or other dimensions), distribution of topics over texts using heat maps and others.

Functions will be designed with consistent syntax and in a way that allows users to grasp easily what they do and why, so users can combine them into scripts to implement their own project ideas with minimal learning effort. The ability to customize workflows will be facilitated by a thorough tutorial describing all functions, outputs and potential combinations in detail (see the tmw tutorial as an example for what we are planning).

Les chercheurs en Humanités numériques intéressés par l’analyse de grands corpus textuels utilisent de nombreuses méthodes et outils issus de domaines informatiques comme le traitement du langage naturel (Piotrowski, 2012) ou l’analyse de réseaux (Lemercier, 2005). Des méthodes récentes fondées sur les réseaux de neurones présentent également un intérêt majeur. Word2Vec est une méthode qui a grandement facilité l’utilisation de tels modèles (Mikolov, 2013). Les différentes optimisations apportées permettent, très simplement, d’entraîner un modèle sur de grandes quantités de données en utilisant un simple ordinateur de bureau. Le code source a été largement diffusé et a rendu cette méthode très populaire, notamment parmi les chercheurs en Humanités numériques. Hamilton a par exemple montré l’intérêt de ces modèles pour analyser l’évolution de certains mots du langage au cours du temps (Hamilton, 2016). Ces méthodes peuvent également être utilisées à d’autres fins. En effet, de nombreux corpus utiles aux Humanités numériques sont issus de processus de reconnaissance de caractères (OCR). Malheureusement, ces processus génèrent très souvent des erreurs, en particulier quand les documents analysés sont de mauvaise qualité (documents anciens ou mal numérisés par exemple). Ces erreurs touchent notamment les entités nommées comme les noms de lieux ou de personnes, particulièrement intéressants pour les chercheurs (Gefen, 2015). Ces erreurs ont un impact majeur sur l’accès à l’information car elles peuvent empêcher d’accéder à toutes les occurrences d’un mot d’intérêt.

Dans ce poster, nous présentons la méthode que nous avons développée pour étendre l’usage de Word2Vec à l’identification des erreurs OCR dérivées d’entités nommées. Après avoir entraîné un modèle sur un corpus donné, chaque mot est associé à un vecteur représentatif. Il devient alors possible de comparer les vecteurs pour extraire des relations morphologiques ou sémantiques entre les mots. On peut par exemple calculer la distance cosinus qui sépare deux mots dans l’espace vectoriel du modèle. Si, au sein du corpus, ces mots apparaissent dans des contextes similaires, la distance qui les sépare sera faible. Or, une entité nommée, bien que mal reconnue par le processus OCR, apparaît souvent dans le même contexte que l’entité originale. En combinant cette distance, qui agit sur les vecteurs, avec une distance d’édition sur les mots, nous pouvons identifier des mots proches sémantiquement et qui possèdent beaucoup de caractères en commun. Cette analyse produit ainsi une liste de termes qui ont toutes les chances d’être des entités mal reconnues par le processus de reconnaissance de caractères.

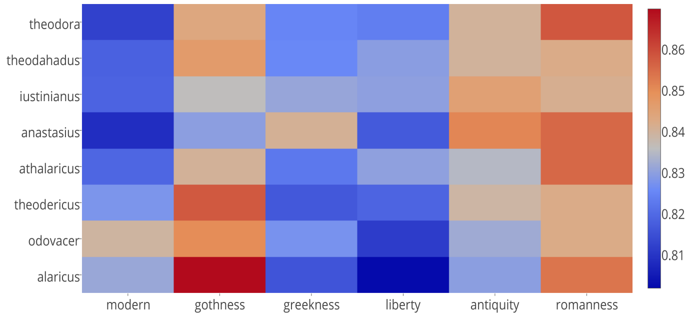

Figure 1: Expérience menée par Bjerva et. al., qui présente les similarités entre différents personnages et quelques grands concepts. Plus une cellule est rouge, plus la similarité est importante.

Une fois les erreurs identifiées, il est possible de s’intéresser à une entité nommée particulière. Sur la base des résultats précédents, nous proposons la construction d’un nouveau vecteur associant le vecteur de l’entité originale et les vecteurs représentatifs des erreurs. Ce nouveau vecteur est le résultat de la combinaison linéaire des vecteurs du mot original et des erreurs OCR. Pour modérer l’importance des vecteurs dans la combinaison, ces derniers sont pondérés selon le nombre d’occurrences du terme correspondant dans le corpus.

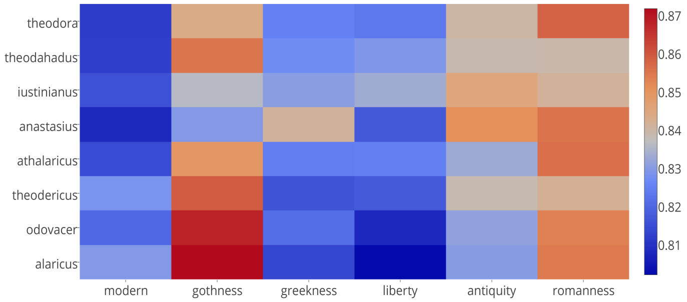

Figure 2: Reproduction de l'expérience menée par Bjerva et. al., avec notre modèle modifié.

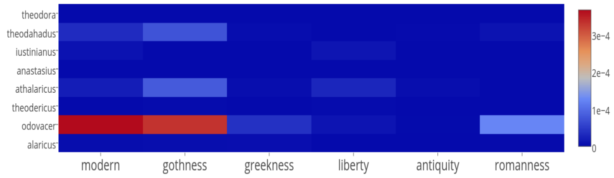

Figure 3: Comparaison des similarités Personne/Concept entre le modèle de Bjerva et. al. et notre modèle modifié. Chaque cellule représente la valeur absolue de la différence de similarité entre les deux modèles. Les cellules rouges présentent le plus de différences.

Nous avons expérimenté notre méthode en reproduisant l'expérience menée par Bjerva et. al. (Bjerva, 2015). Ces derniers se sont intéressés aux relations qu'entretiennent différentes personnalités du VI^{ème} siècle avec de grands concepts (Modernité, Liberté, Gothique, ...). Ils ont utilisé Word2Vec pour entraîner un modèle sur environ 11 000 textes latins, pour ensuite comparer les distances qui séparent les personnes des concepts dans l'espace vectoriel du modèle (voir figure 1). Nous avons utilisé notre méthode pour calculer, pour chaque personne d'intérêt, un nouveau vecteur représentatif prenant en compte les différentes erreurs OCR identifiées. Les distances entre personnes et concepts au sein de notre modèle modifié sont présentées dans la figure 2. Pour plus de clarté, les deux modèles sont comparés dans la figure 3. On peut par exemple observer qu'Odovacer, la personne pour qui les différences sont les plus grandes, est assez peu citée dans le corpus. Notre méthode a cependant identifié de nombreuses erreurs OCR qui ont révélé des informations inconnues au seul vecteur de l'entité originale.

La méthode présentée ici permet d'identifier de potentielles erreurs OCR sur les entités nommées au sein d'un corpus. La prise en compte de ces erreurs peut avoir un impact non négligeable sur le modèle et donc sur les analyses qui en découlent. Cela semble en particulier vrai pour les entités nommées peu présentes dans un corpus.

Body Parts in Norwegian Books

Lars Gunnarsønn Johnsen
yoonsen@gmail.com
National Library of Norway, Norway

Introduction

The goal of the present study is to look at body parts within the class of published Norwegian books. Our main question is to look at the difference between referencing a body part directly from making a reference via a possessive pronoun. The body is important in our culture and is studied both within and outside the digital realm, e.g. the papers in Christopher E Forth; Ivan Crozier (2005) studies the body in culture, while Mahlberg (2013) uses corpus methods in a literary study.

We report on a pilot study that considers body parts across the whole book collection without breaking the collection up into different genres or time periods. Although the pilot study is limited to an across-the-books analysis, it is part of effort to study the effect of different genres, as well as newspapers and journals.

Method and data

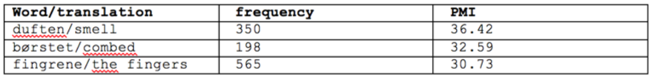
Words for body parts are taken from Norwegian books in the period 1810 up to 2000, using the digitized books made available through the Norwegian National Library, approximately 460 000 books.

The contexts we consider for nouns describing body parts fall into three types as described in Lødrup (2011) and Delsing (1998). Norwegian may express possessives parallel to the English pattern, like "hans arm (his arm)", alongside the definite version like "armene hans (arms.PL.DEF his)". Modern Norwegian seems to prefer the definite plus possessive, in particular for body parts, which therefore will be the construction we focus mostly on here.

A slight complicating factor in Norwegian possessive construction is that sometimes the possessor may not be expressed e.g. Lødrup (op.cit.), in contrast to English, where the possessor cannot easily be replaced with "the" in "John had a pain in his arm" while in Norwegian this is the norm if the possessor is the subject "John hadde vondt i armen/John had pain in the arm".

Each possessor phrase, pronoun plus body part gets a collocation graph as described in Brezina et.al (2015) where each edge in the graph is weighted with PMI (Pointwise Mutual Information, e.g. Lewandowska-Tomaszczyk (2007), Romesburg (2004)). Collocation graphs can be seen as a cluster of words for the phrase generating it, ordered by PMI.

As an example, the first three words in the cluster (or collocation graph) for "håret hennes (her hair)", computed from approximately 12 000 concordance samples, go like this:



Word/translation	frequency	PMI
duften/smell	350	36.42
børstet/combed	198	32.59
fingrene/the fingers	565	30.73

There are 29 Norwegian body words in all going into this study, some duplicated in singular and plural, resulting in 21 unique body parts from head to toe.

Each cluster is cut down to its top 200 words which are then compared using two standard similarity measures, the cosine and the Jaccard-similarity, where the former accentuates similarity of the clusters as weighted distributions, the latter highlights the set equality of the clusters.

Results

Our research question is how references to body parts differ when referenced using a pronoun, or with no pronoun specified. Note that even though no pronoun is specified, it is not required that the reference is done without a possessor, so there will be a certain overlap in the samples.

Our main result is that female and male possessive constructions generate clusters that are closer than standalone body words. Looking at the clusters themselves we see that some is due to the expressiveness of the body, for example "øynene/the eyes", which ranks on top between female and male parts, has words like "glimt/sparkle" and "lyste/lightened" which is used to express emotion emanating from the beholder. These words are absent for the cluster for the word "øyne"eyes". Also, words like "hendene/the hands" in the possessive construction yield words of action like "grep/gripped", "slapp/released", while outside the possessor construction generic actions like "klappe/clap" is found.

The next step is to study these constructions with respect to a distinction between classes of works, using the metadata of national bibliography, and also the difference across media types such as newspapers, books and journals.

Constructing Linked Knowledge around Southeast Asian Studies

Akihiro Kameda
kameda@cseas.kyoto-u.ac.jp
Center for Integrated Area Studies
Kyoto University, Japan

Shoichiro Hara
shara@cseas.kyoto-u.ac.jp
Center for Integrated Area Studies
Kyoto University, Japan

To understand an academic humanities paper, it is crucial to understand each element in the paper (person, place, mention of another paper, etc.). To understand each element in the paper, we have to refer to knowledge outside of the paper; in other words, linked knowledge is important. Linked Open Data (LOD) (Heather and Bizer, 2011), which is emerging from research in the Semantic Web, provides the way to represent and share such linked knowledge.

We prepared texts of "Japanese Journal of Southeast Asian Studies" as a core dataset, in order to attempt to link words or documents in the core dataset to external resources such as DBpedia (also available in Japanese) or the National Diet Library in Japan.

Though LOD has been growing rapidly (Schmachtenberg, 2014), it is difficult to cover specific knowledge in each academic paper. Therefore, the publication of LOD is also an important effort to represent knowledge networks in academic humanities papers.

The Center for Integrated Area Studies, Kyoto University (CIAS) has developed two information tools, named MyDatabase (MyDB) and Resource Sharing System (RSS), to solve these difficulties. The main component of MyDB is a database builder, allowing humanities researchers to construct and revise databases without expert knowledge. MyDB stores metadata and accepts any vocabulary of metadata, including nonstandard vocabularies. This enables humanities researchers to use their own metadata vocabulary according to their own purposes. On the other hand, those metadata varieties make the integration processes difficult. RSS was developed to integrate heterogeneous databases on the Internet, and to provide users with a uniform interface to retrieve databases seamlessly in one operation. Thus, MyDB and RSS have helped accelerate open data in the humanities. However, there are still two problems to solve, especially in the case of RSS: limited coverage of databases and initial costs of integration. First, for example, Kyoto University released KULINE (OPAC), KURENAI (repository), KURRA (archive), Open Course Ware and various databases developed by each research institute in the university, but RSS does not integrate these databases. Second, it is time consuming to integrate new databases into RSS and impossible to trace links automatically. As such, for now, RSS is not the appropriate tool to discover hints and/or create new knowledge.

To overcome these drawbacks, a new project has been launched to develop an innovative information platform for open humanities data. This platform comprises three sublayers. The first layer is "Open Data Layer" which accumulates heterogeneous metadata. This layer uses RDF to describe data of different structures. The second layer is "Data Link Layer." This layer uses ontology techniques such as RDFS and OWL to link ambiguous (uncontrolled) vocabularies and emerge "humanities big data." The third layer is "Application Layer." As big data in the humanities is too huge and complicated to retrieve, categorize, and analyze by hand, this layer provides utilities to process big data. This platform will prepare for APIs to help mashup applications. We expect the platform to reconstruct a knowledgebase from heterogeneous databases, which is used to construct meaningful chunks from scattered data.

Thus, humanities Linked Open Data has been developed, and the "Japanese Journal of Southeast Asian Studies" dataset can be linked to that LOD. This linked knowledge can then help readers from other domains.

This poster session will introduce DH Box, a browser-based platform that provides access to a variety of difficult-to-install digital humanities tools. Currently under development at The Graduate Center, CUNY, and funded by generous assistance from an NEH Startup Grant, DH Box is designed with particular attention to digital humanities pedagogy. Because teaching DH requires infrastructure of various kinds, including computing resources, IT support, and teachers with specialized training, student access to the digital humanities is unevenly distributed and highly dependent on local institutional conditions. Faculty with DH skills are often called upon to teach classes and workshops in adverse circumstances, contending with limited access to labs or other computing resources, restrictive IT policies that prevent new software from being installed, and platform fragmentation on student-owned machines. As a cloud-based platform, DH Box was conceived to address some of these concerns by providing a set of digital humanities tools through a unified computing environment accessed through the browser.

DH Box is not a service, nor is it a standalone application that runs on local computers. Rather, it is software that can be set up by teachers or institutions on cloud-based infrastructure such as Amazon Web Services or DigitalOcean. DH Box is an open-source project developed by and for teachers and researchers in the humanities, and as such is intended to provide an alternative to proprietary services that prevent access to user data. DH Box also makes an intervention in terms of design, UX, and usability. The platform uses a virtualization technology called Docker to quickly create and remove digital working environments, providing students with access to either shared work spaces or individualized virtual machines. Each of these environments contains a set of tools and utilities frequently used in the digital humanities, including IPython Notebooks, the Natural Language Toolkit, MALLET, Omeka, and WordPress. DHBox's tab-based browsing interface makes it possible to easily switch between these utilities, the command line, and a text editor. In addition to providing DH tools in a unified computing environment, the platform offers resources in partnership with institutions like the British Library, making digitized texts available for student exploration. By integrating Git Lit, a tool for downloading text corpora developed in partnership with Columbia University, DH Box provides access not only to digital humanities tools, but also to materials for analysis and experimentation.

Even as it aims to circumvent institutional barriers to DH scholarship, DH Box addresses broader questions of access to DH tools. The necessity for specialized knowledge--use of the command line, importing packages and modules, configuring a working environment--may deter students from pursuing research questions using these novel methods. Making these tools more accessible, on the other hand, should help encourage a new generation of DH scholars. By allowing teachers and students to bypass the difficult process of installation and configuration, the DH Box team hopes to give them room to focus on exploration and experimentation. During the DH Box poster presentation, team members will be available to discuss decisions of design as well as future use cases.

Unpacking Collaboration in Digital History Projects

Max Kemman
max.kemman@uni.lu
University of Luxembourg, Luxembourg

Digital history is concerned with the incorporation of digital methods in historical research practices. Thus, digital history aims to use methods, concepts, or tools from other disciplines to the benefit of historical research, making it a form of **methodological interdisciplinarity** (Klein, 2014). This requires expertise of different facets, such as technology, history, and data management, and as a result many digital history activities are a collaboration of professionals and scholars from different backgrounds. Such collaborations would fit Svensson's characterisation of digital humanities as **a fractioned trading zone** (2011; 2012). Simply stated, this means first that digital humanities functions as heterogeneous collaborations, i.e. with participants from different backgrounds, and second that the participants act voluntarily. In this paper, we will investigate these two aspects in the context of digital history to understand how digital history projects function as heterogeneous collaborations, and what the participants' incentives are for entering such collaborations. We will discuss this by presenting findings from interviews with practitioners in digital history projects, and reflections on projects in which the author himself has participated.

The concept of **trading zones** was coined by Galison who described it as "an arena in which radically different activities could be locally, but not globally, coordinated" (1996, p. 119). That is, although the disciplines of e.g. computer science and history cannot coordinate activities on a global discipline-wide level, and do not contribute towards one another as disciplines, in local collaborations it is possible to communicate and coordinate a shared goal of research within a so-called trading zone. This concept was further developed by Collins et al. (2007) who suggested four types of trading zones using two dimensions. The first dimension is **cultural maintenance** from homogeneous to heterogeneous, i.e., how the two groups define themselves and to what extent they aim to maintain their identity. On this scale, more homogeneous means the two groups become more alike to form a single group, while more heterogeneous means they remain two distinct groups. The second is **coercion** from collaborative to coercive, i.e., what the power relations in the trading zone are. On this scale, more collaborative means the two groups are both acting out of free will, while more coercive means one group is imposing practices upon the other. When a trading zone is heterogeneous and collaborative, we speak of a fractioned trading zone as Svensson does.

One instantiation of this is through **boundary objects**, a concept developed by Star and Griesemer to describe objects used in heterogeneous collaborations where different parties may have different understandings of the object, while the object keeps a common core identity to all parties (Star and Griesemer, 1989; Star, 2010). This concept could be used to refer to the tool under development or the data on which the tool and historian will work. However, in this paper we will approach the project itself as boundary object; the project binds the participants together, but we will ask what each participant expects out of the project, and how participants individually approach the project.

This leads us to the second part of our investigation, the **incentives** for collaboration. When writing about interdisciplinary collaboration in digital history, this is almost always done to underscore the positive or even necessary effects (e.g. Eijnatten et al., 2013; Hitchcock, 2014; Sternfeld, 2011). However, such collaboration is not trivial and requires dedication and investments from all involved, e.g. as shown by Siemens (Siemens et al., 2009; Siemens and INKE Research Group, 2012). In previous research, it has been shown that the incentives for joining a project had a strong influence on the success of collaborations between computer scientists and earth scientists (Weedman, 1998). To understand these incentives, we follow this work and look at reasons for joining the project, individual goals for the project, and expected effects of the participation after the project has ended. From these aspects, we will analyse situations of conflicting interests and expectations. For example, in an interview one historian noted about their project:

> ”[W]e’re supposed to be advising the team developing the tool. And trying to then carry out research on a specific case study. And so originally it was like wow we’re going to be able to use the tool, but very quickly it became clear ok actually probably we’re not going to be able to use the tool.”

In this paper, we will thus unpack the fractioned trading zones of digital history projects, to gain an understanding of how heterogeneous, interdisciplinary collaborations work, and why participants join these collaborations.

MemoryGraph: Digital Critique of Old Photographs Using a Mobile App that Enhances the Interpretation of Landscape

Asanobou Kitamoto
kitamoto@nii.ac.jp
National Institute of Informatics, Japan

Introduction

MemoryGraph is a medium to record memories as the augmentation of a photograph, which is a medium to record photons. MemoryGraph is a new photographic technique that creates a layer of “memories” (or more precisely, time-series photographs) which are taken by the same composition at different times. Photographs of the same composition can be taken by traditional cameras, but this requires substantial effort, because matching a printed photograph with the current landscape requires mental rotation (Shepard et al., 1971), a psychologically demanding task. MemoryGraph simplifies this task through direct overlay of a photograph and the current landscape on a camera viewfinder with adjustable transparency. We demonstrate that this simple idea opens up new possibilities for the critical interpretation of photographs in the context of digital critique.

Related Methods

MemoryGraph focuses on the spatio-temporal relationship between photographs and the real world. This field of interest has given rise to many methods similar to MemoryGraph. For this reason, we begin with a comparison between MemoryGraph and these related methods in order to characterize MemoryGraph’s unique properties.

First, it is necessary to compare MemoryGraph with time-lapse animation, which is also a time-series image of the same composition. The fundamental difference between time-lapse animation and MemoryGraph is in time scale and device dependence. Time lapse animation deals with high frequency observations of seconds to minutes using the same location-fized camera, while MemoryGraph deals with low frequency observations over a period of days to years. These observations may potentially use different cameras that are not fixed at the location. In short, MemoryGraph is a tool to realize fixed point observation at any place for any time interval.

Secondly, we contrast MemoryGraph with augmented reality (AR), which focuses on the alignment of the real space and the virtual space so that a photograph can be seen as an overlay on the real space through a camera viewfinder. On the contrary, MemoryGraph focuses on the overlay of a photograph on a camera viewfinder as a graphic reference to illustrate the composition of a further action (namely, taking a photograph). This key contrast suggests fundamentally different roles between augmented reality and MemoryGraph. Augmented reality is a tool for exhibition, in the sense that alignment is controlled by a tool, while the user is allowed to be a passive visitor who experiences an environment prepared by someone else. Quite the opposite, MemoryGraph is a tool for participation: the "visitor" controls the alignment, and the user should be an active explorer who searches for the best match between photograph and real-life landscape. In short, MemoryGraph is a tool for actions, such as participatory annotation.

Our final comparison discusses photo-sharing services dedicated to old photographs. For example, Historypin (Shift, 2010) is designed to share photographs of the past using a map interface, while an advanced system might use a street-view interface to place photographs in 3D. Both tools aim to link photographs to the real world, however, their methods of achieving this goal do not rely on ventures into the "real world" to "place" the photographs. Photo sharing services depend on "arm-chair" annotators, but MemoryGraph depends on "field" annotators who visit a real place to take another photograph. In short, MemoryGraph is a tool to motivate people to move in the real world.

Proposed Method

MemoryGraph is designed as a mobile app for two reasons. First, the idea of "graphic reference" overlay on a camera viewfinder cannot be implemented on traditional cameras that do not expose API (application programming interface). By re-purposing the viewfinder of a smart phone, MemoryGraph can extend the grid-based reference of a traditional camera viewfinder to a graphic reference such as an old photograph. Secondly, in order employ MemoryGraph as a field work tool, the use of a mobile phone is the best choice for mobility and also for real-time information sharing with the server.

The task of the user is to find the best match between a graphic reference and the real world using an opaque viewfinder with adjustable transparency. Direct comparison between two scenes not only reduces the burden of mental rotation for the user, but also makes the search enjoyable: the movement of the user gives real-time visual feedback that suggests how "good" the move is. This gamification effect motivates users to search for better matching, and promotes photographic crowd-sourcing for participatory annotation.

The outcome of this task is two types of data. One is a photograph that records the current landscape, and another is the metadata of the photograph such as latitude, longitude, and direction observed by sensors in a mobile phone. Metadata may be enhanced later to add a title, and description (among other things), and users can upload metadata and photographs to the server for sharing. The uploaded data can then be used for scholarly research, because the GPS coordinates and the temporally different views of the landscape are valuable resources for understanding the landscape changes.

Results

The MemoryGraph (CODH, 2016) app is available for free on Google Play, but an iOS version has not yet been released. The predecessor app, MemoryHunt (Kitamoto, 2015), has been used for both the study of cultural landscapes and the monitoring of disaster recovery (DSR, 2014).

To study cultural landscapes, we held several workshops with both scholars and laypersons who tried the app in the field. An example is shown in Figure 1, where the reference image was a photograph of Imperial Palace Moat in Tokyo. The photograph was easy to interpret, but the actual place was difficult to find. Figure 2 shows how participants walked along the moat to find the best match. At each place, participants took the photograph that they believed to be the best match, but the best solution of Figure 1 was found after many trials of all the participants.

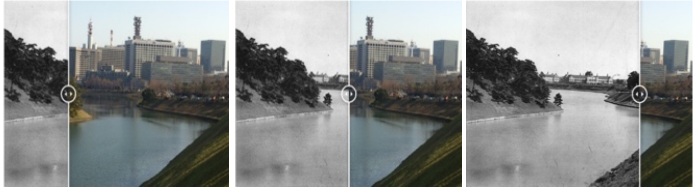

Figure 1. Comparison of two photographs of the same composition. "A view from Miyakezaka to the ministry of justice" taken around 1911 and the current landscape. Courtesy of National Diet Library.

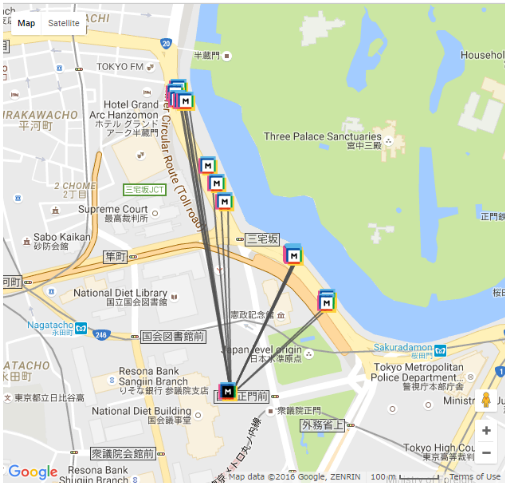

Figure 2. Participants walked along the moat to find the best match, and their trials are marked by icons. The final solution of Figure 1 was obtained at the north end of the moat.

For the second purpose, we held workshops at Kobe in Japan, which was severely damaged by the earthquake in 1995, and Aceh in Indonesia, which was severely damaged by the tsunami in 2004, to understand how the city recovered from the disaster. The app was enjoyed by local people in two countries, and some children were involved more actively than adults due to the gamification effect.

MemoryGraph can be generalized in several ways. First, it can be generalized from landscape to object: for example, time-series photographs of the same person at different places. Second, it can be generalized to cross-media reference: for example, taking the same composition at a "sacred place" of pop-culture work inspired by the real landscape.

Discussion on Digital Critique

Digital critique, or what has been referred to in other words as digital criticism (Kitamoto, 2016) or data criticism (Kitamoto, 2014), was proposed by the author as a framework for digital scholarship in the humanities. It has been applied to the criticism of non-textural sources such as maps and photographs with the intent of using them as evidence for historical studies. Although the digital humanities are often considered quantitative or metric humanities, digital critique focuses on the digital creation and management of humanities knowledge. Several types of digital tools have been designed for the critical interpretation of textual and non-textural sources, including success stories such as the identification of Silk Road ruins, or the characterization of mistakes in the renovation of old Beijing maps (Kitamoto et al., 2014) (Kitamoto et al., 2016). We claim that MemoryGraph is another digital critique tool that asks the following research questions in order to use a photographic source as historical evidence.

The first research question asks what the variance and invariance is in the target landscape over time. Invariance is often found as artificial features such as roads and monuments, or natural features such as a mountain ridge, but in other cases, the identification of invariance requires training of the user in terms of interpretive performance on the historical landscape.

Secondly, we ask how historical evidences can be best integrated across different sources, such as old maps, old photographs and historical databases. Invariance found through the app is a hint to links different sources over time, and this contributes to expanding our understanding by integrating knowledge from different sources.

Our final research question asks why the photograph was taken in this setting. This is because the best match is theoretically achieved by the same physical posture between the original photographer and the user (Kitamoto, 2015). This means that as a user tries to find the best match using the app, a user can re-experience the original photographer who took the photograph in the same posture. The physical overlay of the user and the photographer may lead to research questions investigating the emotion or the way of thinking of the original photographer at the time. This has potential to give birth to new interpretation of photographs from the physical or emotional perspective.

Acknowledgments

The project was partially supported by JSPS Kakenhi Center Grant Number 16H02920 and by Center for Integrated Area Studies (CIAS), Kyoto University. The core contributor to the app is Mr. Tomohiro Ikezaki.

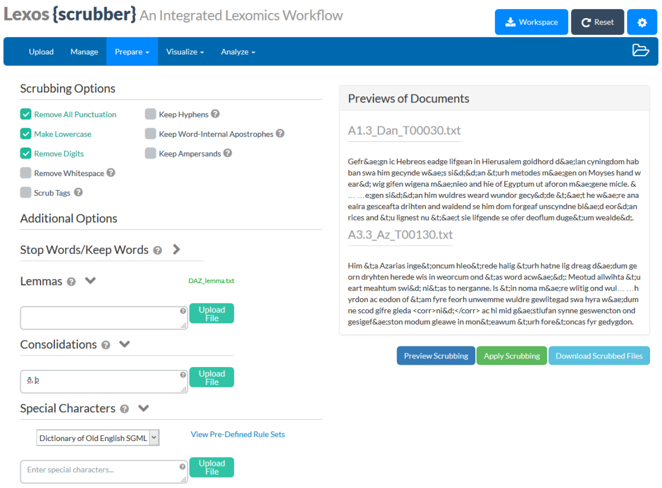
Lexos: An Integrated Lexomics Workflow

Scott Kleinman
scott.kleinman@csun.edu
California State University: Northridge, United States

Mark LeBlanc
mleblanc@wheatoncollege.edu
Wheaton College, United States

Lexos is a browser-based suite of tools that helps lower barriers of entry to computational text analysis for humanities scholars and students. Situated within a clean and simple interface, *Lexos* consolidates the common pre-processing operations needed for subsequent analysis, either with *Lexos* or with external tools. It is especially useful for scholars who wish to engage in research involving computational text analysis and/or wish to teach their students how to do so but lack the time for a manual preparation of texts, the skill sets needed to prepare their texts analysis, or the intellectual contexts for situating computational methods within their work. *Lexos* is also targeted at researchers studying early texts and texts in non-Western languages, which may involve specialized processing rules. It is thus designed to facilitate advanced research in these fields even for users more familiar with computational techniques. *Lexos* is developed by the Lexomics research group led by Michael Drout (Wheaton College), Mark LeBlanc (Wheaton College), and Scott Kleinman (California State University, Northridge). It is built on Python 2.7-Flask microframework, with jQuery-Bootstrap UI, and visualizations in d3.js. The Lexomics research group provides access to an public installation of *Lexos* which does not retain data after a session has expired. Users may also install *Lexos* locally by cloning the GitHub repository.

Lexos guides users through a workflow of steps that reflects effective practices when working with digitized texts. The workflow includes: (i) uploading Unicode-encoded texts in plain text, HTML, or XML formats; (ii) "scrubbing" functions for consolidating pre-processing decisions such as the handling of punctuation, white-space, and stop words, the use of lemmatization rules, and the handling of embedded markup tags and special character entities; (iii) "cutting" texts into segments based on the number of characters, tokens, or lines, or by embedded milestones such as chapter breaks; (iv) tokenization into a Document Term Matrix of raw or proportional counts using character or word n-grams; (v) visualizations such as comparative word clouds per segment (including the ability to visualize topic models generated by MALLET); Rolling Window Analysis that plots the frequency of string, phrase, or regular expression patterns or pattern-pair ratios over the course of a document or collection; and (vi) analysis tools including statistical summaries, hierarchical and k-means clustering, cosine similarity rankings, and Z-tests to identify the relative prominence of terms in documents, document classes, and the collection as whole. At each stage in the workflow the user may download data, visualizations, or the results of the analytical tools, along with metadata about their pre-processing decisions or the parameters selected for their experiments. *Lexos* thus enables the export of data for use with other tools and facilitates experimental reproducibility.



Scrubbing Options

☑ Remove All Punctuation
☑ Make Lowercase
☑ Remove Digits
□ Remove Whitespace
□ Scrub Tags
□ Keep Hyphens
□ Keep Word-Internal Apostrophes
□ Keep Ampersands

Additional Options

Stop Words/Keep Words

Lemmas: DAZ_lemma.txt

Consolidations: ð, þ

Special Characters: Dictionary of Old English SGML

Figure 1: The *Lexos* Scrubber Tool

Lexos addresses three significant challenges for our intended users. The first challenge involves the **adoption** of computational text analysis methods. Many approaches require proficiency with command line scripting or the use of complex user interfaces that require time to master. *Lexos* addresses this problem through a simple, browser-based interface that manages workflow through the three major steps of text analysis: pre-processing, generation of statistical data, and visualization. In this, *Lexos* resembles *Voyant Tools* (Sinclair and Rockwell, 2016), although *Lexos* places more emphasis on and providing more tools for pre-processing and segmenting texts. *Lexos* also shares with tools like *Stylometry with R* (Eder, et al., 2013; Eder, 2013) and emphasis on cluster analysis, providing both hierarchical and K-Means clustering with silhouette scores as limited form of statistical validation. While *Lexos* is not a topic modeling tool, it provides a useful "topic cloud" feature for MALLET data that will be useful for beginners since there are few accessible ways to visualize MALLET output that work well out of the box.

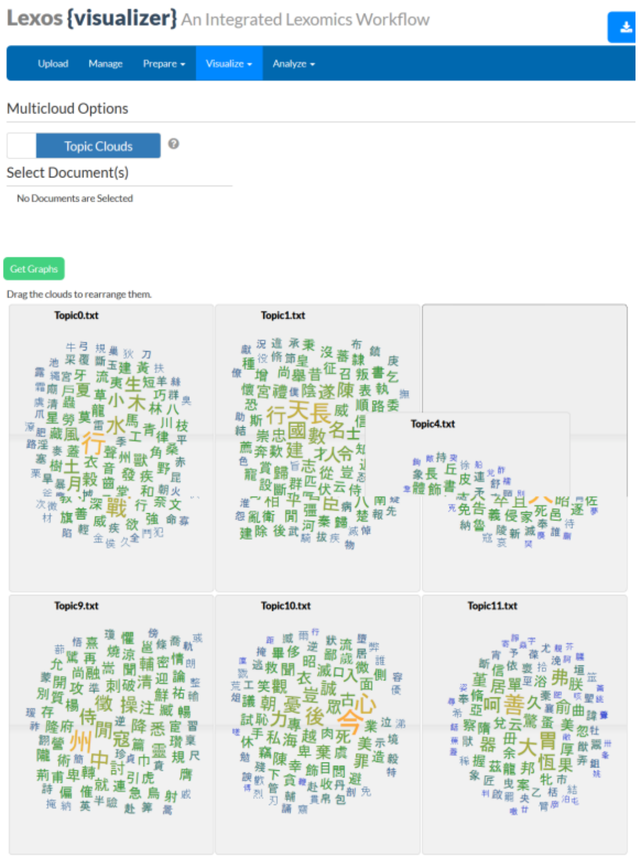

Figure 2: The *Lexos* Multicloud tool showing Chinese "topic clouds"

The second challenge is the **opacity** of the procedures required to move between computational and traditional forms of text analysis. In order to reduce the "black boxiness" of algorithmic methods, *Lexos* contains an embedded component called "In the Margins" which provides non-technical explanations of the statistical methods used and effective practices for handling situations typical of humanities data. "In the Margins" is a Scalar "book" which can be read separately; however, its individual pages are embedded in *Lexos* using Scalar's API, making them easily accessible for users of the tool. *Lexos* shares with tools like *Voyant* an engagement with the hermeneutics of text analysis and attempts to embed "In the Margins" discussion of these issues in the user interface close to the user's workflow. We hope "In the Margins" will host advice and commentary from contributors with the Digital Humanities community.

A third challenge is the **tension** between quantitative and computational approaches and the traditions of theoretical and cultural criticism that dominate the humanities in the academy. As Alan Liu (2013) has recently argued, the challenge is to give a better theoretical grounding to the hybrid quantitative-qualitative method of the Digital Humanities by exploring the ways in which we negotiate the difficulties imposed by "the aporia between tabula rasa quantitative interpretation and humanly meaningful qualitative interpretation" (414). The design of *Lexos* and the discussions in "In the Margins" are intended to open a space for discussion of issues related to the opacity of algorithmic approaches and the limitations and epistemological challenges of computational stylistic analysis and visual representation of humanities data.

This poster presentation provides demonstrations of *Lexos* using some literature from Old, Middle, and Modern English, as well Chinese, which are in our current test suite. We also discuss use cases and best practices, how to install *Lexos* locally, and how scholars may contribute to the still growing content of "In the Margins".

Collaborative Approaches to Open up Russian Manuscript Lexicons

Kira Kovalenko
kira.kovalenko@gmail.com
Austrian Academy of Sciences, Austria

Eveline Wandl-Vogt
eveline.wandl-vogt@oeaw.ac.at
Austrian Academy of Sciences, Austria

In this paper, the authors introduce a new research collaboration between the Institute for Linguistic Studies (St. Petersburg, Russia) and the Austrian Academy of Sciences, Austrian Centre for Digital Humanities (Vienna, Austria), and exemplify multicultural, crossdisciplinary collaboration on the Ph.D project of Russian manuscript lexicons.

The project is aimed at the online representation of the Russian manuscript lexicons, which reflect a very important stage in Russian lexicography and served as a basis for the printed dictionaries appeared later. This lexicographical genre (called azbukovnik in Russian) appeared in the middle of the 16th century on the base of glossaries, and differ from them by the alphabetical order of the word entries. About 150 manuscripts, mostly from the 17th century, containing the lexicons came into our hands. The tradition of copying manuscript lexicons preserved in the Old Believers communities, and the latest lexicon dates from the beginning of the 20th century. Lexicons were classified by L.S.Kovtun in the 1989, and some additions were made later by K.I.Kovalenko (for details see Kovalenko, 2016).

Obligatory parts of the word entries were head word (or collocation) and explanation. Word entries could also contain inscription of the language source for loan words, lexicographical or literary sources, citations, and information about topic groups (animals, birds, plants, etc.). Sometimes, observations on various linguistic topics were included in the word entries as well. Despite the great importance of these lexicons as Russian language history resources, only small part of them is available for researchers (2 published in Kovtun, 1975 and 1989, and 16 can be found online as a facsimile.

The research idea is formulated collaboratively by the Russian and Austrian scholars, experienced in (traditional) lexicography as well as in digital transformation and research infrastructure development. An architecture to embed the Russian manuscript lexicons into a larger lexical resources infrastructure is developed based on these visions and needs at the Austrian Academy of Sciences. Cornerstones of the architecture are opening up lexical resources and develop as much as possible (due to different types of licensing) freely available resources to the broader public which meet the open science definition.

The established architecture consists of three layers:

1. **The human interface layer:** supports data access e.g. list of headwords, geographical map, timeline and other visual approaches etc., which is further developed with every new project. Furthermore, via authentification it offers a private workspace.
2. **The persistent layer:** offers a data repository, e.g. triple store, open access repository to sustainable store and interlink data.
3. **The enrichment layer**: offers opportunities and tools to interlink data and collaboratively enrich data, e.g. with Wikidata or Europeana.

Ideally, all Russian manuscript lexicons in text format and as facsimiles should be included in the research data environment. As a first step, main representatives of each lexicon type are represented. The plain text is marked up in TEI and is provided with metadata which include standardised form of the head word, information about its origin, foreign etymon for loan words (such as ἀπόστολος for апостолъ) and topic group designation. Word entries contain metadata about lexicographical or literary sources. In case that the facsimile is available, it will be presented along with the text form of the lexicon.

The project is aimed, on one hand, at the representation of the most important lexicons in marked up textual form and as facsimile (if possible). On other hand, the search engine embedded in the infrastructure will make it possible to create enquiries to the data and make selections such as: words according to their origin, literary or lexicographical sources, words belonging to a particular topic groups and so on. The manuscripts will be semantically exploited and concept-based, interlinked with knowledge resources in the linked open data framework (for more details see Kovalenko et al., 2016). For example, interlinking with Europeana will increase the accessibility and reusability of the data. Thus, the project will make Russian lexicons available and open them for further research and for public curiosity.

The poster will introduce the collaborative approach, the roles of the partners and their contributions, discuss the technical framework based on the research approach and present recent results the first time.

The project is connected to the COST action IS 1305 European Network of electronic Lexicography (ENeL).

Editing Melville's "Billy Budd" with TextLab, Juxta Editions, and MEL Catalog

Nick Laiacona
nick@performantsoftware.com
Performant Software Solutions, United States of America

Overview

During the creation of the Melville Electronic Library (MEL), we have developed a suite of software applications that, taken together, provide a powerful system for the creation of critical archives. In this software demonstration, we will demonstrate how these applications work, using the editing of Herman Melville's *Billy Budd* as an example. We will demonstrate the editorial process from the initial encounter with a manuscript leaf to the publishing of a web based reading text complete with a critical apparatus and editorial notes.

We will demonstrate the use of the following software applications:

- TextLab
- Juxta Editions
- MEL Catalog

Textlab

Billy Budd comes to us in the author's original manuscript, existing print editions, and many other media instantiations. This multiplicity is what John Bryant, the chief editor of MEL, refers to as a “fluid text.” (2002). TextLab aids in the transcription of the manuscript, the presentation of the manuscript facsimile, and the production of a base text. TextLab also aids in secondary editing, which is the process of identifying alternative readings at points of revision in the editing process. The ultimate aim is to retain the fluid quality of the text using digital tools.

TextLab’s team environment allows several editors to work simultaneously and independently on the hundreds of leaves of manuscript material. The interface pairs an XML editor with a high resolution image, and deep zoom functionality, allowing close-up viewing of the manuscript.

Textlab transforms TIFF images of the manuscript leaves into "pyramidal TIFFs" and serves them using a IIIF compliant image server.

The editor provides a set of XML elements and controlled vocabularies, which are pre-established by the editorial protocols of the edition. The transcriber can mark revision sites on the image using a drawing tool and then link these to the corresponding XML elements that record them. The transcriber can also validate the XML and preview the diplomatic rendering of the leaf before submitting it for inclusion in the edition.

As transcribers complete their work, the lead editor assembles the submitted transcriptions into a base text. TextLab aids in this process too, allowing the editor to reorder leaves and organize chapters without having to change the XML. In the end, a base text is produced, with diplomatic renderings of each leaf coordinated with the facsimile images. An XML version of the base text is stored in MEL Catalog, which is then retrievable by Juxta Editions.

Juxta Editions

Once a base text has been prepared using TextLab, it is then loaded into Juxta Editions twice. The first copy of the base text is kept for collation with other existing editions. Juxta creates a heat map visualization as well as a side-by-side comparison of the existing versions of the text. The second copy of the base text is then lightly edited for grammar and consistency. This produces a reading text which can then be added to the set of texts being collated.

The reading text is then annotated by the project team. As editors annotate the text, they can link passages to the MEL Catalog's database. Editors may link passages in the text itself or in the editorial notes.

When the text of "Billy Budd" is ready for publication to MEL, it is published using a customized Jekyll template. Visitors to the site will be able to read the text, trace Melville's words back to the original manuscript, and explore alternative readings through secondary editing and collation.

MEL Catalog

The MEL Catalog is a database of places, events, artwork, people, and texts from Melville's life and work. It is linked to name authorities such as the Getty Art and Architecture Thesaurus, so that the edition is compatible with linked open data. MEL Catalog can be used to search MEL as well as cross-walk on the objects it collects. MEL Catalog also has support for storing GIS data which can then be fed to mapping software the travel itineraries of persons both real and fictional.

Impact

Through a real-world example, this poster session will demonstrate how three specialized tools, used in conjunction, create a flexible, powerful and coherent process, which allows scholars to contend with source materials and produce digital editions more easily, and more quickly. We will also provide an explanation of how attendees can use these, and other compatible tools, for their own scholarship.

Generative Model For Latent Reasons For Modifications

David Lassner
davidlassner@mailbox.tu-berlin.de
TU Berlin, Germany

Problem

The idea that writing makes its way from the authors first draft manuscript to the intended reader without any detours or modifications is often inaccurate and oversimplified. In general, the author or a close person performs corrections and stylistic modifications in subsequent iterations. Additionally, there may be an editor or even an official censor who perform censorship of too private or too extreme parts of the document. The different versions of a document generated by these correction layers often become intransparent in printed versions of the document, while manuscripts are more likely to display traces of how the document has been modified to its current state. The digital scholarly edition "Letters and texts. Intellectual Berlin around 1800" (Baillot, 2016, IB in the following) combines genetic edition and entity annotation. The corpus encompasses literary and scholarly testimonies by a group of people, who influenced the intellectual Berlin between Enlightenment and Romanticism. The genetic encoding gives precise information regarding deletions and additions in the manuscript text. However, the reason for these modifications is not encoded. Three main domains for reasons why to modify such a document as a letter in the intellectual context of the time around 1800 have been identified:

1. Correction of mistakes
2. Stylistic modification
3. Moral censorship based on the topic

This paper proposes an unsupervised machine learning approach, which assigns the according reason to every modification. The proposed method focuses on dealing with stylistic modifications and moral censorships. I am aiming to increase the accessibility to manuscripts, by providing a structure for the modifications and to assist in evaluation of certain modifications. Furthermore the proposed method may be applied on different editorial problems, which I will discuss in the Outlook section.

Method

As brought up in the Problem section, the proposed method focuses on stylistic and moral censorship reasons, based on the assumption that these two types of reasons relate to the topic of the modification. I convey a generative topic model, that is based on Latent Dirichlet Allocation (D. Blei, Ng, & Jordan, 2003) and is able to take into account the structural information of modifications. There exists a wide range of topic models that customize LDA and many of these take into account additional structural information. To replace the Bag-of-words approach by introducing structural information about the word order is a major field of LDA research (Gruber, Rosen-Zvi, & Weiss, 2007; Wallach, 2006). Moreover there exists a lot of research on topic hierarchies (D. M. Blei, Griffiths, & Jordan, 2010; Paisley, Wang, Blei, & Jordan, 2015). LDA has also been modified to work with graph-structured documents (Xuan, Lu, Zhang, & Luo, 2015). However I am not aware of any literature that shows how to model modification reasons in a corpus of natural language.

Figure 1 illustrates the conceptual functioning of the method from left to right. As input on the left, a collection of documents is given. The documents have parts marked as modified. The generative model in the center infers reasons by taking into account all text, inside and outside the modifications. Every reason may stand for a stylistic, or a certain moral censorship reason (e.g. political, religious). On the right side, the model outputs a reason-modification assignment.

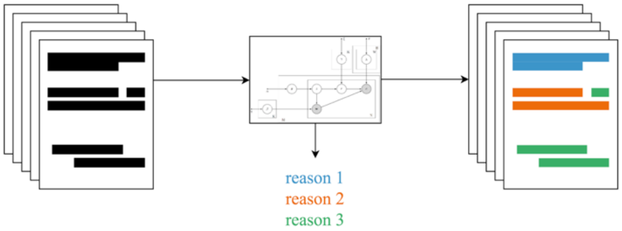

Figure 1: The generative model in the center receives input documents with modifications. It outputs reasons for modification and a reason assignment to each modification

In addition to the LDA latent variables, I introduce a topic-reason variable γ, a word-reason-modification tendency λ and a token-reason assignment r. The complete model in plate notation is shown in Figure 2. c (observed) models whether a token has been modified. For every topic, γ holds a distribution over reasons, which may cause a modification. For most modifications this distribution should be sparse, for example if a censor crosses out a sentence that discusses the financial situation of the author, the the topic and the reason for censorship would be identical. On the contrary a stylistic modification wouldn't always have one or two clear corresponding topics.

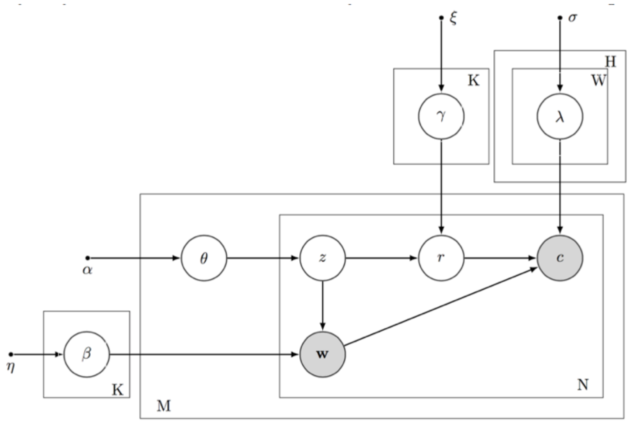

Figure 2: Plate notation of the model. The left four circled variables represent LDA, the right ones the modification part

For every token and every reason, λ holds a distribution over two states, namely whether the token tends to be modified for this reason. There may be token, that are representative for a topic, but they nonetheless do not tend to be modified. The categorical variable *r* represents the reason assignment at that position.

The latent variables can be iteratively approximated using Variational Inference (Bishop, 2006; Zhao, 2013).

Intermediate results

In this section, evaluation methods on toy data are discussed and characteristics of the IB data set, as well as preparation steps and first intermediate results are presented.

Toy data

To evaluate the characteristics of this method, experiments with artificial toy data can be performed. The generative model described above can be employed for inference as well as for generating artificial documents with modifications. A typical experiment to evaluate a generative model is conceived as follows:

1. Initialize the latent variables of the model randomly
2. Generate documents with modifications
3. Re-initialize the latent variables
4. Try to infer the latent variables from the generated documents

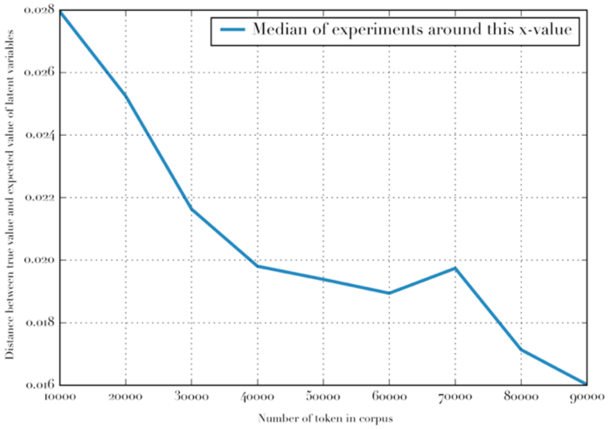

Figure 3: Experiment with 585 generated corpora varying the size from 10.000 to 90.000 token and performing inference for z, r, θ und γ, leaving the remaining model parameters fixed

I have performed a series of experiments to investigate the sensitivity of the model to corpus size. As expected, the accuracy of the model increases with an increasing amount of data. Figure 3 shows a decreasing distance between the true value and the expected one, when increasing the size of the data set. The accuracy does also largely depend on the sparsity of the concentration factors, which means that in order to predict the minimal size a real data set should have, one has to come up with according prior concentration factors for the Dirichlet variables.

IB data set

To apply this method on the IB data set, some preprocessing steps are necessary. Apart from standard natural language preprocessing, one has to filter out all corrections of mistakes.

Table 1 shows the change of data set characteristics that are caused by the pre-processing. A lot of modifications have been considered to be corrections of mistakes and thus have been filtered out.

The visualization in Figure 4 reveals a great variety in the structure of the modifications. The figure shows the state of all tokens of two letters from the IB data set. The upper letter contains a lot of small changes, where often a green (added part) and red (deleted part) occur as a combination. The letter below contains a lot of longer deleted parts, concluding, that the letter above contains corrections of mistakes, whereby the lower contains modifications related to the topic.

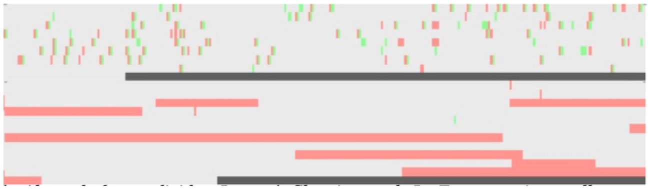

Figure 4: Above dark grey divider: Letter 4, Chamisso to de La Foye contains small corrections. Below: Letter 14, Dorothea Tieck to Uechtritz contains larger modifications. Deletions (red), additions (green)

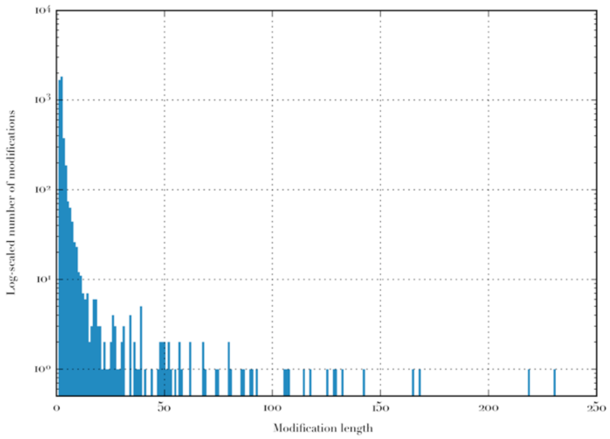

Figure 5: 93% of the modifications are shorter than 6 token. Two outliers of length 349 and 470 have not been included in the visualization

The size of the modifications seems to be a criterion to distinguish between corrections and topic related modifications. The distribution over the length of modifications however, reveals, that a lot of the modifications in the data set are small, thus likely to be corrections of mistakes (Figure 5).

The first preliminary experiments have been carried out with a binary setup: The model should distinguish between a) one particular moral censorship reason and b) everything else. To do so, prior knowledge about the topics has been introduced to the model in form of a keyword.

For example the topic sickness has been introduced to the model by the keyword “Krankheit”. The first results on this look very promising, as they reveal a precision = 1 and a recall = 0,67.

Outlook

In the near future, I will undertake further experiments with the IB data set. To do so, I will incrementally increase the number of modification reasons. The results will be made accessible as part of the IB corpus, making the permeability between editorial and algorithmic work more visible and accessible to all interested DH communities for reuse.

In a further step, I would like to look into different applications of this method. A promising idea would be, to look into different editions of the same text and consider each difference as a modification.

The project "Hybrid Narrativity" combines work by language and literature studies, cognitive psychology, and computer science with the overarching goal to arrive at an empirically founded narratology of graphic literature, including comics and graphic novels. Comics and graphic novels provide a unique cultural form that has developed its own vocabulary, allowing for a fascinating interplay of text and visual art. After a period of neglect, they have recently been theoretically analyzed in detail by scholars in the arts, humanities and linguistics (McCloud, 1993; Groensteen, 2007; Cohn, 2013). Our aim is to provide an empirical testbed for these theories. The foundation of this endeavor is a large collection of graphic novels, which are annotated using a variety of methods. These include high-level descriptions of the work, mid-level descriptions of pages and panels, including the actors / characters, text, objects, and panel transitions, and low-level descriptions of visual elements in terms of descriptors developed in computer vision such as color histograms, GIST, SIFT, and SURF features. We are currently evaluating the addition of mid-level features from deep networks trained on photographs of real-world scenes, with quite promising first results.

These descriptions in terms of material properties are complemented by eye-tracking data, providing an empirical measure of the reader-level attention distribution and the time course of attention shifts. Thus, the digitized representation of literary and artistic works includes information on the side of "recipients", that is, readers, viewers, spectators and appreciators with their psychological and physiological responses. In a first step, eye-tracking data on a small sample of pages from selected works were collected from a large number of participants in order to evaluate general principles of attentional selection in graphic literature. Results show that reading of graphic novels is primarily governed by reading of text, and that inspection of graphical elements is apparently governed by top-down selection of story-relevant elements. In perspective, eye-tracking data will be collected for each of the works in the corpus, using a sample of pages and a smaller number of readers.

A graphical annotation tool is in development and has first been released to the public at DH 2016. This tool is based on an XML dialect that allows for the annotation of language as well as graphical elements. Future versions will include OCR support for comics fonts, and provide customizable annotation schemes, allowing other researchers to implement their own research ideas. We will also briefly present ideas on the potential to incorporate gaze-based interaction in the user interface of the tool, e.g., for the intuitive selection of objects, which will become important with the projected availability of low-cost eye trackers in the near future.

We have developed the Graphic Novel Markup Language (GBML) as an extension of John Walsh's Comic Book Markup Language (CBML; Walsh, 2012) to facilitate the description of graphical elements. These descriptions are imperative for defining regions-of-interest based mapping of eye movement data to the stimulus material. Material has been annotated using our editor, and a custom R package is under development and in use for statistical analysis of eye movements. Visual features are currently extracted using OpenCV (Bradski, 2000, 2016) and VLFEAT (Vedaldi & Fulkerson, 2008) libraries from Python and Matlab, since R does not yet provide sufficiently extensive packages for this purpose (for a promising approach see imager, Barthelmé, 2016). Deep features are based on Deep Gaze II (Kümmerer, Wallis, & Bethge, 2016), which is in turn based on the VGG-19 network (Simonyan & Zisserman, 2014). A description of artworks in terms of visual features has shown promising results in other domains (Elgammal & Saleh, 2015).

A number of analyses using the corpus data show the potential for comparative studies as well as detailed study of individual works. Many of the testable hypotheses can be derived from the theoretical work cited above. For example, McCloud (1993) speculated that the cognitive effort of the recipient depends on the kind of panel transition, or that the empty space between panels is used to signal the passage of time. We provide empirical support for both of these hypotheses. Other examples include visual trends that can be identified across time or between regions, linguistic and visual analyses that can be used to compare text and visual complexity between different genres, and network analyses of interactions between characters that allow for an easy quantification and visualization of roles within a work, and for a comparison between works. They can also be used, e.g., to compare the complexity of a novel and its adaptation to the graphic novel format.

An in-depth analysis of a single work, the graphic novel adaptation of Paul Auster's City of Glass by Paul Karasik and David Mazzucchelli, shows that readers of graphic literature benefit from a specific expertise in decoding the different channels of information conveyed by image and text. Comics experts spend significantly more time on the image part of the panels, and this is correlated with a significantly deeper understanding of the narrative. New data suggests that this pattern replicates across samples, labs, and languages.

Taken together, we present the design of a corpus of graphic literature that is annotated using a variety of levels, including readers' eye movements. Ideas for how to make use of these data for interactive future versions are developed, and analyses of the collected data in terms of description as well as reception of the works of art are presented.

SLaTE: A System for Labeling Topics with Entities

In recent years, the Latent Dirichlet allocation (LDA) topic model (Blei, Ng, and Jordan, 2003) has become one of the most employed text mining techniques (Meeks and Weingart 2012) in the digital humanities (DH). Scholars have often noted its potential for text exploration and distant reading analyses, even when it is well known that its results are difficult to interpret (Chang et al, 2009) and to evaluate (Wallach et al, 2009).

At last year's edition of the Digital Humanities conference, we introduced a new corpus exploration method able to produce topics that are easier to interpret and evaluate than standard LDA topic models (Nanni and Ruiz, 2016). We did so by combining two existing techniques, namely Entity linking and Labeled LDA (L-LDA). At its heart, our method first identifies a collection of descriptive labels for the topics of arbitrary documents from a corpus, as provided from the vocabulary of entities found within wide-coverage knowledge resources (e.g., Wikipedia, DBpedia). Then it generates a specific topic for each label. Having a direct relation between topics and labels makes interpretation easier, and using a disambiguated knowledge resource as background knowledge limits label ambiguity. As our topics are described with a limited number of unambiguous labels, they promote interpretability, and this may sustain the use of the results as quantitative evidence in humanities research (Lauscher et al, 2016).

The contributions of this poster cover the release of: a) a complete implementation of the processing pipeline for our entity-based LDA approach; b) a three-step evaluation platform that enables its extensive quantitative analysis.

Entity-based Topic Modeling Pipeline

Figure 1 illustrates the computational pipeline of our system; python classes are represented in rectangles. First of all, a set of text files is imported into the system and several preprocessing steps are applied to the textual content. Next, the data is sent to the entity linking system TagMe (Ferragina and Scaiella, 2010), which disambiguates against Wikipedia. As a result of this step, for each document a set of related Wikipedia entities is retrieved. Now, the data is inserted into a MySQL database.

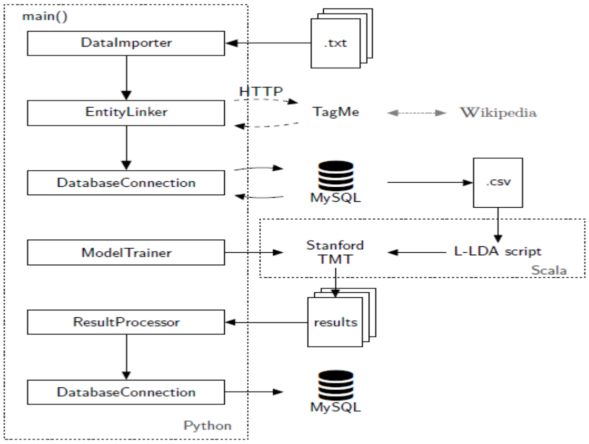

Figure 1. Architecture of the pipeline

Afterwards, the TF-IDF measure is computed over the entities, which we use to rank all the entities for each document in descending order. Then, the top k entities as well as their corresponding documents are exported into a comma-separated values file that is given as input to the L-LDA implementation of the Stanford Topic Modeling Toolbox. Finally, after running L-LDA and applying several post-processing steps, we obtain a document-topic distribution saved in the database in which each topic is described by an unambiguous label linked to Wikipedia.

The whole source code is available for public download on Github. Given a working Python, Java, and Scala runtime as well as a running MySQL installation our pipeline is ready directly out-of-the-box. The specific configuration according to the user's needs can be made via a simple text file.

Three-Step Evaluation Platform

Document Labels

In order to assess the quality of the detected entities as labels we developed a specific browser-based evaluation platform, which permits manual annotations. This platform presents a document on the right of the screen and a set of possible labels on the left (See Figure 2). Annotators are asked to pick labels that precisely describe the content of each document. In case the annotator does not select any label, this is also recorded by our evaluation system.

Entities and Topic Words

In order to establish if the selected entities were the right labels for the topics produced, we developed two additional evaluation steps. Inspired by the topic intrusion task (Chang et al, 2009), we designed a platform that permits to evaluate the relations between labels and topics using two evaluation modes: For one evaluation mode (that we called Label Mode - Figure 3), the annotator is asked to choose, when possible, the correct list of topic-words given a label. For the other, he/she was asked to pick the right label given a list of topic words (aee Figure 4). In both cases, the annotator is shown three options: one of them is the correct match, while the other two (be they words or labels) come from other topics related to the same document.

Mr President, the fact that the security situation in Kosovo continues to be precarious prompted the Committee on Foreign Affairs, Human Rights, Common Security and Defence Policy to give particular attention to the deficiencies in the conduct of the European Agency for Reconstruction in Kosovo, which the Court of Auditors has highlighted. These include the amount of cash held in reserve, the need to avoid making payments to unauthorised persons, and the need for better coordination between the Agency's accounting officer and the competent directorate of the Commission. Statements by the Agency in response to these points have made it possible for these concerns to be laid to rest. The Foreign Affairs Committee is well aware of the difficult circumstances under which the Agency does its work. Let me say by way of conclusion, though, that the amount spent by the EU on aid must be rationally proportionate to its political benefit. The discharge report offers an opportunity to make that point. Whilst giving the agency discharge for the year 2002, we do expect the extension of its remit to the management of EU aid in Serbia, Montenegro and Macedonia to result in long-term improvements in efficiency and hence to the political stabilisation of the region.

Journaux intimes francophones en Russie au XIXe siècle : une approche textométrique de l'interaction entre langues et cultures

La rédaction de journaux intimes en français était un phénomène assez répandu parmi les élites russes au XIX^{e} siècle. Les aristocrates de l'époque apprenaient souvent le français dès le plus jeune âge et continuaient à pratiquer cette langue tout au long de leur vie. Le français n'était cependant pas leur langue maternelle, et leurs écrits offrent des données précieuses sur l'interaction entre les deux langues et cultures. Par ailleurs, certains journaux présentent de grandes qualités littéraires et artistiques (grâce aux dessins d'auteur qui les accompagnent) et méritent d'être plus largement connus par la communauté académique et le grand public.

Le projet présenté dans ce poster est porté par une équipe franco-russe de l'Université d'état de Novossibirsk et de l'École normale supérieure de Lyon. Il vise à analyser et à publier numériquement plusieurs corpus, dont les journaux d'Alexandre Tchitchérine et d'Olga Orlova-Davydova.

A. Tchitchérine, lieutenant au régiment Semionovski de l'armée russe, a tenu son journal de septembre 1812 à août 1813, son manuscrit contient 83 illustrations, dont la plupart en couleurs. Son texte a été traduit en russe et publié (Chicherin 1966), mais cette traduction dont les qualités littéraires sont indéniables, est parfois inexacte et présente des lacunes. L'original français de ce journal est inédit.

Les journaux d'O. Orlova-Davydova (1814–1876) sont le fruit d'un vaste projet autobiographique que l'auteure a mené tout au long de sa vie. Ces journaux n'ont jamais fait l'objet d'une recherche scientifique. Dans le cadre du présent projet les passages francophones de ses journaux (1830-1847) servent de corpus pour étudier le bilinguisme de l'auteure et pour déceler les voies de formation de personnalités bi- ou plurilingues dans la Russie du XIX^{e} siècle (Debrenne 2016a et 2016b). Le noyau du corpus est constitué par une copie des journaux d'Orlova-Davydova réalisée vraisemblablement à sa demande et corrigée par sa propre main. Ce document est conservé à Novossibirsk, à la Bibliothèque scientifique et technique de la Branche Sibérienne de l'Académie des sciences russe (BST). Il fait partie du fonds patrimonial Tikhomirov (http://www.spsl.nsc.ru/rbook/ogl_tix.html).

Les journaux du corpus sont transcrits et « encodés par stylage » dans un logiciel de traitement de texte (Microsoft Word) de façon à permettre une conversion quasi-automatique dans un format XML-TEI enrichi d'un certain nombre d'annotations. Il s'agit de repérer et de classer les différents types d'erreurs par rapport au français standard de l'époque (orthographiques, grammaticales ou lexicales), de recenser les différents types d'entités nommées présents (index hiérarchique), ainsi que les différents passages rédigés en russe. La conversion se fait en deux étapes : d'abord à l'aide de l'outil de conversion en ligne Odette (Glorieux 2015), puis avec une feuille de transformation XSLT spécifique au projet. Après validation formelle, la forme finale des sources est importée dans la plate-forme TXM (Heiden et al. 2010). TXM permet d'analyser et de publier des corpus complexes encodés en XML-TEI en combinant des outils de traitement automatique de la langue (TAL :tokenisation paramétrable, étiquetage morphosyntaxique avec TreeTagger), de philologie numérique (éditions présentant de façon synoptique le fac-simile de la source et plusieurs niveaux de transcription), et d'analyse qualitative (recherche de motifs lexicaux avec le moteur plein texte CQP) et quantitative (analyse de spécificités, analyse factorielle de correspondances, etc.). Le projet utilisera les outils de TXM pour lire de façon intégrée l'édition du texte avec les illustrations correspondantes. Il permettra également de synthétiser le vocabulaire utilisé juste devant les passages en russe et étudier les emprunts français propres à chaque auteur par rapport à la langue russe. Les illustrations ci-dessous présentent un exemple d'encodage XML-TEI dans les sources d'un dessin situé au début d'une page du journal de Tchitchérine (Fig. 1) suivi de la copie d'écran d'une visualisation synoptique correspondante dans TXM de la transcription comprenant le dessin et le fac-similé du manuscrit (Fig. 2).

Archivlo: Digitizing the Archival Research Workflow

Zoe LeBlanc
zoe.leblanc@vanderbilt.edu
Vanderbilt University, United States of America

E. Kyle Romero
eulogio.k.romero@vanderbilt.edu
Vanderbilt University, United States of America

This poster describes the development and uses of Archivlo, an application for improving the archival research workflow and enabling a more collaborative digital research community. In recent years, digital history has emerged as a vibrant subfield of the digital humanities community (see Robertson, 2016; and Weingart, 2016).Currently, the majority of digital history projects rely on digitized corpuses or community compiled datasets. However, the archival materials used in these projects represent only a small fraction of the archival sources that scholars currently utilize in their research.

Moreover, the proliferation of digital cameras and scanners has resulted in a wealth of archival material for scholars, but this digitized archival data is usually scattered across hard drives. To organize this data, scholars currently either keep notes or re-purpose bibliographic software.

Data management software provide some solutions to dealing with this abundance of material (such as Devonthink, Evernote, Zotero, and most recently, Tropy) but individual scholars often must invest a great deal of energy and time replicating the organizational structure of the archives to make sense of their research. This siloed approach to archival research makes finding information about archival collections or other scholars working in the archives difficult. Archivlo is designed to solve these problems, and create a more coherent workflow for organizing archival data.

This poster will outline the development and design of Archivlo, from the early idea stages to our initial beta model. Archivlo is currently in progress, and the poster will share our experience building a web-based application, as well as designing a user interface that privileges data interoperability and flexibility. Archivlo is written in Python and Angular, and is fully open-source on Github. To access archival data, Archivlo utilizes archives' APIs and web page annotations to allow researchers to find collections. Users are able to save their archival collection research in their profile, and indicate whether they have worked in these archives or are interested in using the archive. This functionality adds efficiencies to how scholars locate and keep track of their archival research. Users can also export their records to multiple file formats, as well as other data management software, such as Zotero andDevonthink.

Additionally, Archivlo enables users to share their lists of visited and interested in archives, which we believe will help scholars share information about archives and potentially even form collaborations. For archivists, Archivlo can also provide data on user interest vis-a-vis usage of their archival collections. We believe our experience with Archivlo will be of interest to other digital humanities developers and project managers, as well as digital humanists who work with archival collections.

Previous efforts to encourage digital collaboration among researchers in archives have, with a few exceptions, largely faltered, with most of these projects requiring a high technical literacy to contribute to a database or extensive time to transcribe records (see Mostern and Arksey, 2016. Moreover, these efforts to construct large databases of archival data have been forced, through copyright restrictions, to limit their scope to material that is either from prior to the early twentieth century or born digital materials). Instead of requiring large resources to digitize materials or standardize collections, Archivlo presents an alternative solution to this problem - focusing on how scholars work with archives to enable more digital and collaborative research. We believe Archivlo will encourage more productive data management practices among scholars, and reduce inefficiencies in the archival research workflow. Much of Archivlo's goals remain experimental, and the opportunity to present our work at DH 2017 would help us share our progress and consider future directions for the tool.

Ultimately, we hope that Archivlo can help further the digital humanities ethos of digital collaboration, and present one solution for using tools to help foster digital research communities.

Research Subject and Issues

Musical organization in popular music is a complex research subject. While significant work has been done in the last few decades to theorize popular music (e.g. Moore, 1992, 1995; Tagg, 2009; Biamonte, 2010; Attas, 2011), these theories tend to rely primarily on score-based parameters such as harmony and, to a lesser extent, melody and rhythm. However, in popular music, scholars have observed that audio-based features such as perceived loudness and timbre play an important role in musical organization (e.g., Everett, 2001; Temperley, 2007). To empirically evaluate the relevance of these features to various theories, it would be appropriate to supplement the traditional melodic and syntactic approaches with acoustical approaches. Empirically oriented musicological surveys of popular music have become more and more popular. However, as is the case with more traditional musicological research, studies on harmony still occupy the core of the research that has been published in the last decade (e.g. Mauch et al., 2007; de Clercq and Temperley, 2011, Temperley and de Clercq, 2013; Burgoyne et al., 2011; Léveillé Gauvin, 2015). This underrepresentation of large-scale research focusing on other parameters such as pitch content and perceived loudness in popular music may in part be attributed to the lack of corpora with such data.

Objectives

The aim of the current project is to gain unique insights into popular music by assembling a new database that will combine score-based and audio-based parameters. As such, we are releasing melodic and lyric transcriptions, as well select signal-processing data to supplement a subset of 100 songs from the already publicly available McGill Billboard Database (Burgoyne et al., 2011).

Sample

The McGill Billboard Database is a systematically sampled, professionally curated collection of harmonic transcriptions for more than 700 distinct songs that made the Billboard Hot 100 weekly charts between 1958 and 1991. Along with time-aligned chord transcriptions, each file features metadata regarding the title of the song, the performing artist, the chart date, the highest rank the song ever achieved on the Billboard Hot 100 chart, and the number of weeks the song spent on the charts. Our corpus focuses on a 100-song collection taken from the original McGill Billboard Database. More than 70 unique artists are represented, ranging from 1958 to 1991.

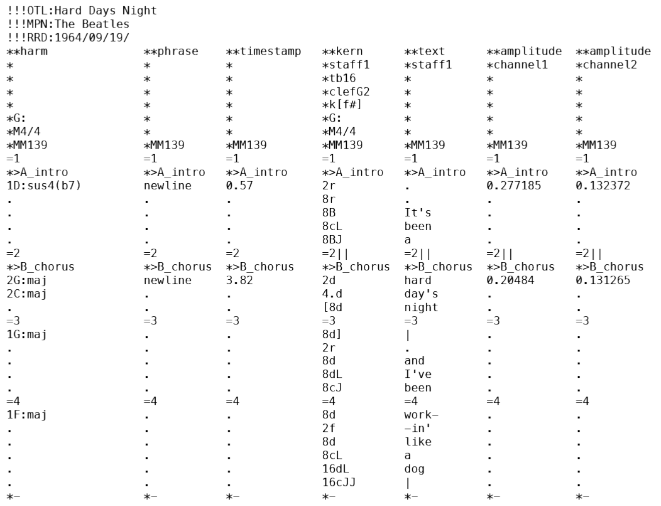
Transcription Process

All songs were divided and assigned randomly among a group transcribers, including the authors. Each transcriber was in charge of finding the appropriate recording matching the original chord transcription from the McGill Billboard Database and transcribing melodic and lyrical information using their preferred notational software. In order to alleviate discrepancies among the different transcribers, a set of guidelines in the form of a “Transcription Style Guide” was established and distributed prior to the transcribing process. This file stipulated minimum requirements for every transcription, as well as general instructions on how to notate potentially more challenging pitch nuances, such as slides, scoops, and ornaments.

We used the timestamps already available in the original McGill Billboard Database to automatically retrieve acoustical information. The data was encoded separately for the left and right channels, thus maintaining information related to stereo panning.

Encoding Format

We opted to encode the new transcriptions in the Humdrum format. Humdrum (Huron, 1995) is both a syntax to encode music information in ASCII representation and a set of tools dedicated to the manipulation of such files, alleviating the problem of having to write a dedicated parser. Figure 1 represents a typical Humdrum file in our corpus.



```

Figure 1: Example of a complete transcription in the Humdrum format

Impact and Future Work

We hope that this new collection of musically-rich data will yield new and unexpected research on popular music, and allow possibilities that were, up until now, virtually impossible. We believe that supplementing traditional score-based data (e.g. harmony and melody) with lyrics and loudness descriptors is a necessary step into developing a holistic theory of form in popular music.

Our plans for the future are manifold. We hope to increase the size of our corpus, with the goal to eventually provide complete annotations for every harmonic transcription in the McGill Billboard Database. We also wish to continue supplementing this corpus over the next several years with more detailed data. More specifically, we hope to have instrumental solos, drumming patterns, back vocals, and more acoustical information, including spectral annotations.

Acknowledgment

This research project was supported by the Fonds de recherche du Québec - Société et culture. Special thanks go to Dana DeVlieger, Lissa Reed and Gary Yim for their help.

Introduction

Word Formation Latin (WFL) is a derivational morphology resource for Classical Latin, where lemmas are analysed into their formative components, and relationships between them are established on the basis of Word Formation Rules (WFRs). For example amo (to love) and amator (lover) are connected with a relationship that describes a change from a verb to a noun through the addition of a suffix (-a-tor) that in itself bears semantic information (in this case it characterises agentive and instrumental nouns, i.e. someone or something performing an action).

WFL has received funding from the European Union's Horizon 2020 research and innovation programme (Marie Sklodowska-Curie grant agreement No 658332-WFL). The resource is still a work-in-progress - having so far covered 5,366 morphological families, 268 WFRs, 22,679 relations - and is due to be completed by October 2017. The lexical basis used for the resource comprises the whole 69,682 lemmas featured in the morphological analyser for Latin LEMLAT 3.0.

The word formation lexicon is built in two steps:

1. Word formation rules (WFRs) are detected using a mixture of previous literature on Latin derivational morphology (Jenks, 1911; Fruyt, 2011; Oniga, 1988) and semi-automatic procedures (Passarotti and Mambrini 2012).
2. WFRs are applied to lexical data: lemmas and WFRs are paired using a MySQL relational database, and a number of MySQL queries provide the candidate lemmas for each WFR. Input and output pairs are then checked manually, in order to clear out false friends and duplicate results due to homography.

This poster will describe the resource and illustrate the web application that is being developed to easily access the data.

The WFL dataset is both integral part of Lemlat and used in a standalone web application. The database will be made available for download, so that extensive queries can be run and the data can be used and reused at will. The web application is intuitive and user-friendly. It supports those scholars and students that are not familiar with database querying languages such as SQL, but also Classicists with specific scientific questions.

The lexicon can be browsed either by WFR, affix, input and output Part-of-Speech (PoS) or lemma. Drop-down menus provide the available options for each selection, such as the list of affixes and lemmas. Results are visualised as lists of lemmas and tree graphs, whose nodes are lemmas and edges are WFRs. Trees are interactive. Clicking on a node shows the full derivational tree ("word formation cluster") for the lemma reported in that node. For example, figure 1 shows the word formation cluster for the lemma computo, 'to calculate'. Clicking on an edge shows the lemmas built by the WFR described by that edge. Methodological motivations will be given for each browsing option together with suggestions for potential uses of the web to investigate Latin derivational processes. Four browsing choices can help the scholar with an array of linguistic investigations.

1. By WFR - opens research questions on a specific word formation behaviour; for example, it is possible to view and download a list of all verbs that derive from a noun with a conversive derivation process (e.g. radix 'root' -> radicor 'to grow roots').
2. By Affix - acts similarly as above, but works more specifically on affixal behaviour: for example, it is possible to see all agentive nouns in -tor and verify how many correspond to a female equivalent in -trix.
3. By PoS - useful for studies on macro-categories, such as nominalisation or verbalisation.
4. By Lemma - useful when studying the productivity of one specific morphological family (like the one for bellum above) or a group of morphological families.

These explorations lead in many directions through investigations on derivational production and semantics (Can semantic identification of outputs help to show which WFRs are more morphotactically transparent? Which inputs produce a certain kind of outputs? Etc.).

The poster will illustrate a few applications of the resource and a demonstration of case studies. The poster will be accompanied by a live demonstration.

American Panorama: An Atlas of United States History

Justin Madron
jmadron@richmond.edu
University of Richmond, United States of America

Nathaniel Ayers
nayers@richmond.edu
University of Richmond, United States of America

Introduction

The poster will focus on the Panorama Toolkit built by the Digital Scholarship Lab at the University of Richmond (DSLUR) and Stamen Design. The first section will outline the capabilities of the toolkit then turn to examples from DSLUR's American Panorama project.

The focus of the toolkit is on the richly dynamic capabilities of modern web maps to enable deep digital scholarship on American History. The components are built on the foundation of open source tools including React and Leaflet libraries -- creating an extensible, public, collaborative framework that will support the continued development of future maps in our Atlas or the user's maps of choice. The components within can be installed via npm and integrated into any web-facing project. American Panorama also includes a template that can be used as a starting point for maps in the American Panorama Atlas, or for other projects that aim to use Panorama components. All of the components are "views" (meaning they appear in the DOM) and use React.

Since it is open-source, people can contribute and add new components that can be used individually, or wired together to create dynamic visualizations. The flexibility of the toolkit allows for a range of complexity, which has been seen in the five maps currently available. We envision this being used not only in academia, but in other projects varying in subject and purpose.

To highlight the possibilities of the toolkit, we will focus on University of Richmond's American Panorama, a series of online maps that use interactive mapping features and innovative cartographic design to encourage active investigation of American History. For over a year, the DSLUR has been working with Stamen Design to investigate spatial exploration across various subjects in 19th and 20th century U.S. history. These maps—which make up the Atlas—cover a wide range of topics designed to communicate knowledge about some facet of American history to audiences that include students, scholars, and the general public.

In 2015, Stamen and the DSLUR collaborated on the first four maps of the Atlas. The first map covers the forced migration of enslaved people before the Civil War, highlighting the change in net importation and exportation of slaves to and from different parts of the South for each decade between 1810-1860. The migration across the Overland Trails to the West focuses on the routes emigrants took envisioned through the writings in their journals, along with the locations of forts, ferries, and bridges. The movement of people and goods through canals highlights not only the location of canals, but visualizes the goods that moved along them. The immigration of people to the U.S. from 1850 to today shows Foreign-Born populations at various scales from country level to county level.

The collaboration between Stamen and DSLUR was the key driver to the success of the first four maps. We combined the knowledge and narrative ideas of DSLUR and the visualization skills of Stamen to translate new knowledge into inviting, elegant displays that respect the complexity of the subjects. American Panorama combined two deeply passionate teams to create not just four deeply engaging maps, but also a toolkit of reusable visualization components that could be used for future atlases in the American Panorama.

In 2016, DSLUR employed the Panorama toolkit to build the fifth map in the American Panorama series, a visualization of the Home Owners' Loan Corporation (HOLC) redlining maps from the early 20th Century. Using the visualization tools developed by Stamen, DSLUR created Mapping Inequality, which updates the study of New Deal America, the federal government, housing, and inequality with twenty-first century tools and scholarship. It offers unprecedented online access to the United States government's collection of "security maps" and area descriptions produced between 1935 and 1940. The toolkit allowed the use of cartographic visualizations like concentric circles, which arguably were the spatial episteme of cities for early twentieth-century Americans. These Concentric circle diagrams visualize the relative distribution of HOLC grades in relation to the center of the city.

The toolkit's capabilities are seen in the fifth Atlas map, Mapping Inequality. The foundational components, as well as the flexibility of the software, allowed DSLUR to create an engaging, invoking map highlighting the practice of denying access to mortgages and other forms of credit to neighborhoods based upon discriminatory practices, which later became known as redlining. This last installment of the Atlas showcased that this can be used by anyone wanting to create a project using the capabilities of modern web mapping seen in American Panorama.

Between Page and Screen by Amaranth Borsuk and Brad Bouse: Translating an AR poetry book

Piotr Marecki
piotr.marecki@ha.art.pl
Jagiellonian University, Poland

Aleksandra Małecka
aleksandra.malecka@ha.art.pl
Jagiellonian University, Poland

Our poster is devoted to the English-Polish translation of the augmented reality book *Between Page and Screen* by Amaranth Borsuk and Brad Bouse. The prominent digital media scholar K. N. Hayles wrote about the relationship between the analogue and the digital: “In the contemporary era, both print and electronic texts are deeply interpenetrated by code. Digital technologies are now so thoroughly integrated with commercial printing processes that print is more properly considered a particular output form of electronic text than an entirely separate medium.” *Between Page and Screen* is an illustration of these processes on one of the possible reading levels. The authors tell the tale of the relationship between the analogue book and digital screen in the form of an epistolary concrete poetry dialogue between two protagonists, P. and S. The nature of the relationship is underlined by the fact that the work comprises of a traditional book with QR codes (sold in bookstores) and an online application for reading it. The two platforms are inextricably joined in the reading process (which cannot take place if one of the links is missing). The translation of the book and application involves innovations and challenges unheard of in the case of conventional books. Our poster is a visual guide through the process of translation and publication of the AR book in Poland.

Creating the data base

Borsuk and Bouse’s work can be seen as a piece of constrained writing. The authors tell their story with a selected vocabulary. The letters by P. and S. highly employ words that stem from the Indoeuropean roots of the words “page” and “screen”. The authors used lists of related words found in the respective entries in the *American Heritage Dictionary of Indo-European Roots*. In the Polish translation, the translators recreated the same principle for the Polish words “kartka” and “ekran”, but given that there is no one comprehensive dictionary of Indo-European roots for the Polish language, they created similar lists based on the study of several etymological dictionaries of Slavic languages. The etymological and lexicological research was the first, crucial step of the translation process.

Comparing the data bases

Given different linguistic contexts and different lists of related words, it becomes clear that the dialogues and characters of the analogue and digital protagonist (in Polish K. and E.) will differ between the source and target language. It was thus necessary to reinvent the characters based on the new vocabulary ranges.

Conceptual translation

Given that word-for-word translation was impossible with the above-mentioned constraint, the translators decided to recreate the logic of the book, loosely following the plot of the English original. The final translation is rather a translation of the concept than a direct translation of the text.

Visual adaptation

The work by Borsuk and Bouse can be also seen as concrete poetry. The QR codes in the book have a visual aspect to them themselves. In interaction with the online application, they launch animations, which in their shape and movement reflect the verbs or nouns used in them. Given that the word resources of the Polish and English works are different, the shapes of the animations were also changed.

Use of software

The application was written with the FLARToolkit, thus, any changes, from content to features like diacritics, were introduced with the use of this tool.

Publication and distribution

The last element of this procedure is traditional computer typesetting of the book and introducing it into distribution as well as launching a website dedicated to it.

The translation of electronic literature remains an understudied area. One of the reasons for this is the acceptance of the status quo that most available, created and read works are in English. This is connected with several difficulties in translation and adaptation of electronic literature (working with code, working with a given platform). There are often several issues connected with the idiomatic character of the work (both on the level of content and platform). Our poster also does not offer a ready formula for the translation of such works – it is a case study of one work, considered emblematic of the phenomenon of AR books. The methodologies of medium specific analysis (K. N. Hayles), as well as exploratory programming (N. Montfort), the terms bookishness (J. Pressman) and liberature (Z. Fajfer and K. Bazarnik) provide the vocabulary that will allow us to describe and visualize the performed process.

The Creative Computing Lab in Poland

Piotr Marecki
piotr.marecki@ha.art.pl
Jagiellonian University, Poland

Jakub Woynarowski
j.woynarowski@gmail.com
Academy of Fine Arts Krakow, Poland

The poster is devoted to the project we are currently working on at the Jagiellonian University with digital media artists, programmers, and theorists: the creative computing laboratory. The main aim of this team is to research the creative process in its widest definition in the era of digital textuality. Digital literature is the focus of our study, above all highly computational literature. In the laboratory environment a team of artists, theorists, and programmers are working on the forms of contemporary creative programming, closely tied to the choice of programming language and the platform on which the work is written. One of the project's aims is to create digital artwork in the laboratory system, and to produce an academic description of the process. The invited artists, theorists, and programmers are gathered in three spheres of creative programming: text generators, interactive fiction, and experiments with augmented reality. One of the outputs of the project is a catalog and an archive of programed works, both for research and for teaching. The team is also focusing on the phenomenon of homegrown “writing under constraint” techniques, which are seen as precursors to creative programing techniques. As part of our search for original and undiscovered phenomena in the humanities, we are researching the local demoscene as an example of creative teamwork in digital media. This project is being carried out as a transdisciplinary task, at the crossroads of computer studies, literary studies, creative writing, experimental literature, and digital media. It also develops new tools in humanities research (laboratory teamwork) and new genres and communication practices (technical reports, open notebook science). As part of the project we are producing expressive processing (presupposing knowledge of the code) and platform studies (presupposing thorough knowledge of the capabilities of the platform where the works are written) tools for describing digital works. One of the aims of the project is to create a retro platform archive, as well as an archive of Polish works written for various platforms.

The poster will present the team's one year experience (the lab was launched in May 2016). We will focus on the most important terms in the dictionary useful for the lab's team, methods developed in collaboration between theorists, artist and programmers working together in the academic context. Moreover, we will build a guide on how to build such an institution in the geopolitical, economic and cultural context, which determine the scope of our research, approach, structure and significance of the lab. By describing our lab, we try to tackle trends that are relevant to contemporary studies on digital media, taking into account and affirming the local perspective, which is different from the dominant one.

The Victoria Press Circle

Miranda Marraccini
mcm5@princeton.edu
Princeton University, United States of America

The Victoria Press began as an outgrowth of SPEW (Society for Promoting the Employment of Women), a group of Victorian feminists who sought to provide new avenues for women's work in the printing industry. SPEW activists, led by Emily Faithfull, set up a Press where women worked as compositors (Tusan, 2004; Fredeman, 1974). Presswomen printed anthologies, tracts, and feminist periodicals, including the monthly English Woman's Journal (1858-1864), which published mainly contributions by women. Publication of the English Woman's Journal (EWJ) spanned "the period between the failed attempt to reform legislation that prevented married women holding property in 1857 and the equally unsuccessful attempt to win female suffrage in 1867" (Mussell, 2008). Articles in the EWJ promoted both of these reform measures and advocated for female employment in different fields, as well as other contemporary feminist causes. My use of the term "feminist," though anachronistic to the movement, has been accepted by other scholars writing about the period, who choose the word to demonstrate an active and purposeful engagement with the continuous struggle for women's rights (see Phegley, 2004; Mussell, 2012; Frawley, 1999).

My digital project, The Victoria Press Circle, funded by Princeton's Center for Digital Humanities, offers open-access network visualizations of the women and men involved in the Victoria Press, based on contents of the EWJ and three anthologies printed at the Press between 1861 and 1863. The Victoria Press Circle's first aim is reconstruction: the project helps to establish the history of the Victoria Press, since there is no existing archive. This is especially important since the EWJ includes a high percentage of unsigned contributions (about 40 percent). None of the women who published in the EWJ currently have significant digital representation. Identifying them as individuals combats the critical undervaluing of texts in female-produced periodicals, and studying them as a group highlights authors who may not receive attention individually.

Furthermore, this project demonstrates collaboration. A network-focused approach is particularly appropriate because the Victoria Press was constructed on a material model of collaborative female labor. Its founders explicitly attempted to build a hub of social interaction around the Press, creating venues to promote women's rights. SPEW members saw their office as a meeting place for women advocating for female employment:

It is also the intention of the Society to render their office a depôt for information of every kind relating to the employment of women. Curious and interesting facts will be collected. Extracts from newspapers, pamphlets, and speeches on the subject, will be gathered together, and kept for the inspection of members of the Society (EWJ, 1859).

In creating network graphs, I am reconstructing how the Presswomen built a social network for themselves, not imposing intentionality on their project (Weingart, 2013). All of my data will be freely available and downloadable in .csv format for other researchers to access and use.

Ultimately, The Victoria Press Circle's open-access website will display at least three network visualizations, constructed in Cytoscape, of those involved in the Press: one composite graph for the three anthologies; one graph for the EWJ; and one combined visualization for all the publications. Cytoscape, though a tool designed for biomolecular analysis, is more flexible than Gephi for social network analysis, especially for specific functions of filtering based on node and edge attributes and on network statistics (see Shannon, 2003).

In addition to literary contributors, my visualizations include compositors, engravers, printers, editors, and paper manufacturers. Marianne Van Remoortel (2015) has helped in identifying names of compositors from newspaper reports and census data. While the individual model of many digital archives privileges authors and minimizes others involved in literary production, the women of the Press were working at every level of print culture to advance their social aims. By valuing all types of contributions equally, my visualizations illustrate their collaborative effort. The Presswomen's project echoes through current debates in digital humanities about the necessity of learning to code for engagement in DH work (Dinsman, 2016). I believe that programming can be a feminist act for scholars, just as involvement in print culture was a feminist act for Victorian female authors. The artisan practice of printing is analogous to the artisan practice of coding, and both are affected by experiences of gender, race, class, and sexuality. I hope to use my project to show how women worked with their hands and their pens in tandem, and how I'm continuing that work today.

Humanities At Scale – Creating A Network Of Expertise And A Sustainable Infrastructure For Digital Humanities Projects In Europe

Markus Matoni
matoni@sub.uni-goettingen.de
State and University Library Göttingen, Germany

Jenny Oltersdorf
oltersdorf.jen@gmail.com
FH Potsdam, Germany

Dirk Roorda
dirk.roorda@dans.knaw.nl
Data Archiving and Networked Services, Netherlands

Digital Humanities (DH), as a growing field, generates lots of innovative new tools and methods to enhance work in humanities disciplines. To ensure a sustainable digital European infrastructure for long-term availability of digital research data and tools the DARIAH infrastructure (Digital Research Infrastructure for the Arts and Humanities) aims at the development of a strong cooperation and information exchange between research communities and institutions in the arts and humanities. The ambition to extend this community and create a European-wide network of expertise was one of the reasons to initiate the new Horizon 2020 project Humanities at Scale (HaS).

The project coordinated by DARIAH-EU aims to evolve the DARIAH community, offer training and information material, set up a number of training workshops and develop core services within a sustainable framework. Within this framework a research infrastructure to connect DH research tools, services and data will be established and the challenge is to build technical systems to support this.

The poster will highlight and answer the following questions from a technical perspective:

- How can a decentralized framework (architecture of participation) of tools and services be developed and maintained?
- Which kind of technologies are useful to establish a sustainable framework for DH-tools and -services?
- What is needed to integrate externally developed tools into such a framework?

The DH community, as a network of expertise, created and still creates a lot of important tools and services - often only in a specific project context or for one particular research question. To make these tools and services accessible, re-usable, and open for DH, HaS is building a sustainable technical framework which will advance the creation and enhancement of digital tools. This will improve applications, enlarge possibilities for publication and enable long-term preservation of research data and digital methods. Just hosting digital tools is not sufficient. Code and server configuration require constant maintenance and ongoing development - an elementary issue for a decentralized and unified infrastructure. Thus, within the HaS project, researchers and developers get conceptual and technical support for their tools and services to enable a better integration into the community.

Furthermore, projects in the Digital Humanities need key central services. They often must spend a large proportion of their available resources on basic infrastructure components. To investigate demands regarding service requirements and tools a survey was conducted in summer 2016. Its aim was to get an overview of the currently used services and tools and the ones, which will become relevant in the future. The survey design enabled a gap analysis focusing on the following three kinds of tools and services:

- Development services such as Git/SVN, Chili or Open Project. They support developers in code hosting, code review, the development of workflows and documentation. They improve the organization and quality of code and the workflows for writing it.
- Hosting services comprise virtual machines, storage and repository solutions, configuration management tools and monitoring environments. They provide basics for a sustainable development and ongoing operation of DH services.
- Collaboration tools support the whole area of DH. Collaborative writing and managing of digital content in a content management system are major ingredients of everyday's work.

To connect all services and tools HaS will define requirements to enhance the integration.

Besides these enabling, generic tools, the DARIAH community is also producing highly specific research tools that we need to take into account. That will be organized as a bottom-up process, drawing information from existing tools that have been contributed to DARIAH or tools which are offered as candidate contributions. In order to harvest their characteristics, HaS is building a contribution registry, called the DARIAH Inkind Tool. It should not only collect technical specifications, but also generate an overview of what is available in terms of research capabilities. And last but not least, the registry will be used to assess the cost and value of the DARIAH contributions. The existence of the Inkind registry will enable the DH community to muster a lot of information about each tool, such as documentation, use-cases, application descriptions, data examples, research scenarios and particular training possibilities.

The general aim of the poster is to present the results of the project to the community to get important feedback. This includes the chance to present the participants of the poster-sessions a live-demo (German and English) of the contribution registry. All in all, the presentation will provide insights on how we face sustainability from a technological view.

Designing from a Narrative: Leveraging the 6 Point Story Method to Facilitate Interaction Design in Digital Humanities Projects

Shane McGarry
shane.mcgarry.2015@mumail.ie
Maynooth University, Ireland

One of the many challenges facing Digital Humanities projects today is how to design for alternative approaches to traditional close reading. Many of the current interface mechanisms for representing text are drawn from their print counterparts and are directly reflective of the analogue. These mechanisms rely upon traditional representations of text and typically structure content using techniques that have been leveraged by print for several centuries. However, these various mechanisms are designed to support traditional close reading techniques and often fail to consider digital reading methods. As digital content has become more ubiquitous and commonplace, a demographic shift has occurred, migrating readers towards alternative methods of reading and engagement with text, alternatives which seek to augment the traditional close reading approach. Previously conducted research shows a decline in traditional close reading techniques when moving from print to digital (Hayles, 2012; Mangen, 2008). This, along with other factors, has led to the emergence of new methods of reading and textual engagement, such as hyper reading, radial reading, and distant reading (Hayles, 2012; McGann, 2012; Moretti, 2013). However, finding metaphors or interactions which support these different modalities can be challenging, and the methods for discovering how users leverage content can often be inconsistent.

In an effort to increase user experience within the Digital Humanities space, the field has turned to interaction design techniques in order to better understand how the user leverages these types of projects (Ruecker et al, 2011; Pierazzo, 2014). Traditionally, interaction design has borrowed from social science in an effort to create focus groups or usability studies which provide insight into how the user interacts with the software in question. Various techniques—such as ethnography, surveys, and interviews—are often leveraged with the goal of understanding how the individual engages with the software. However, these techniques typically fail to consider why the user may engage with the software in question. This assessment, otherwise known as the “emotional impact” of the software, can have tremendous impact upon the reader’s interaction with the content. Studies have shown that the subjective experience often has a strong impact upon metacognition (Ackerman & Goldsmith, 2011), leading readers to demand more than just efficiency and usability from a platform: they also require emotional engagement (Shih and Liu, 2008). This poster proposes the “6 Point Story Method” as a framework which can be used to assess not only how the reader seeks to interact with the content but also why.

The “6 Point Story Method” is a psychological method developed by Alida Gersie. The method is primarily used by psychologists as a therapy modality to assist patients by framing stories which often have subconscious meaning and acting as an assistant to uncover issues requiring further therapeutic intervention (Dent-Brown and Wang, 2004). This poster proposes that this method can be adopted for use in the early stages of interaction design with the goal of facilitating idea generation in a group setting in order to further understand: the goals of end users, what challenges the users may face when navigating a software system, and the driving motivation behind the use of the platform (thus forming the emotional component of the analysis). This poster will discuss the use of the 6 Point Story Method within a focus group setting whose primary goal is to further explore how users wish to engage with Digital Humanities projects from non-traditional engagement methods (e.g. in support of reading modalities outside of traditional close reading). The methodology, including the demographics behind the focus groups, will be illustrated and the results will be explored in order to highlight the advantages of adapting the 6 Point Story Method to support traditional interaction design techniques.

Mapping Violence: Visualizing State-Sanctioned Racial Violence on the Mexico/Texas Border (1900-1930)

Jim McGrath
james_mcgrath@brown.edu
Brown University, United States of America

Monica Martinez
monica_martinez@brown.edu
Brown University, United States of America

Cole Hansen
cole_hansen@brown.edu
Brown University, United States of America

Edward Jiao
edward_jiao@brown.edu
Brown University, United States of America

This poster will describe recent work on *Mapping Violence,* a digital project that makes visible decades of state-sanctioned acts of violence in the United States during the first decades of the twentieth century. From 1900 through 1930, vigilantes and Texas Rangers killed hundreds of ethnic and national Mexicans along the Mexico/Texas border. "A man's life just wasn't worth much at all," recalled eyewitness Roland A. Warnock, "There were so many innocent people killed in that mess that it just made you sick to your heart to see it happening." This period of conflict is one of the largest episodes of civil unrest in American history and still impacts the struggle for justice and civil rights that continues today in Texas and in America at-large. However, this history is widely unknown. Like *Visualizing Emancipation* (University of Richmond), *Digital Harlem* (University of Sydney), and other projects that remind us of the hyperlocal stories and histories of particular geographic regions, *Mapping Violence* aims to recover and make accessible lives, events, and acts of oppression that continue to impact later generations in various ways.

Mapping Violence is part of *Refusing to Forget*, a public humanities initiative involving collaborators from Brown University, Loyola, Texas A&M, the University of Texas, and

South Texas College (among others) that is working to raise awareness about this history of racial violence and its legacies. *Mapping Violence* is complemented and informed by additional endeavors by the *Refusing to Forget* team: academic articles and books, applications for Texas historical markers acknowledging this history, collaborations with Texas public school educators to develop curriculum, and exhibitions of material with the Bullock Texas State History Museum. In *Mapping Violence*, we envision a project that functions as a database of primary and secondary sources for researchers studying this history, a curated and dynamic resource for classroom use, a memorial space that honors and remembers the victims of these acts of violence, and a corrective to historical narratives and commemorations that erase or mute these moments in the history of Texas, Mexico, and the United States.

This poster will document recent and ongoing work at Brown University on the completion of the first public-facing iteration of *Mapping Violence* (currently scheduled to launch in the fall of 2017). It will provide an overview of the creation of a database of material derived from primary and secondary texts, narrate the iterative processes of mapping and annotating data about state-sanctioned violence, and consider the ways in which the design of the project is informed by its stakeholders and its range of imagined audiences (educators, academics, activists, students, among others). The poster will highlight the significant roles undergraduate collaborators (from a range of academic disciplines including Computer Science and Ethnic Studies) have played in the project at various stages: as researchers, programmers, designers, developers, and curators. We will also document the project's timeline, workflow, and challenges. What are the challenges inherent in creating a digital space that is both an act of commemoration and a source of research (challenges faced by projects with similar inclinations like *Our Marathon: The Boston Bombing Digital Archive* and *The 9/11 Digital Archive*, among others)? In what ways can database creation and digital curation productively remediate and recontextualize controversial historical events for public audiences? How do we navigate desires to tell hyper-specific, localized stories about individual victims of violence with inclinations to inventory and resituate these events within larger narratives about race, gender, and nationalism?

A working demo of *Mapping Violence* will accompany the poster, provided there is room and available resources to do so.

Public Humanities: In Search of a Field

Jim McGrath
james_mcgrath@brown.edu
Brown University, United States of America

Robyn Schroeder
robyn_schroeder@brown.edu
Brown University, United States of America

Inge Zwart
inge_zwart@brown.edu
Brown University, United States of America

Like the phrase "digital humanities," "public humanities" has proven difficult to pin down, even by practitioners who have come to value this term as an accurate description of their research interests and institutional affiliations. It has been a term used (primarily, but not exclusively, by institutions of higher education in North America and by grant-funding agencies like the National Endowment for the Humanities) to describe various forms of cultural production: physical and digital acts of curation, archival initiatives, community outreach, educational programming, and public arts initiatives. It has ties to terms like "public history." More recently, investments in "public humanities" have more frequently intersected (and at times elided) investments in "digital humanities," given the public-facing imperatives of many digital projects and practitioners. Are all digital humanities projects also inevitably public humanities initiatives? When the phrase "public humanities" is invoked, who is most often speaking, and to what do they refer? Who is most likely to fund projects with explicit ties to this term, and what communities are served and financed by these efforts? When practitioners of public humanities write about the value of their work, who do they cite? More generally, what forms, contexts, people, places, geographic regions, occupations, and communities is the term "public humanities" tied to, and who is missing, obscured, erased, or otherwise apart from these conversations?

This poster will document recent efforts by public humanities practitioners at the John Nicholas Brown Center for Public Humanities and Cultural Heritage (Brown University) to survey and reflect upon both the ten-year history of the Center (and its M.A. program in Public Humanities) and, more generally, the state of "public humanities" as a field of critical inquiry. Postdoctoral researchers and graduate students at the Center have determined that the institutional memory of the Center would benefit greatly from an indexed archive of primary materials (syllabi, photographs, exhibition materials, student projects and writings, among others) as well as a collection of oral histories from major figures in its history (directors, staff, faculty, graduates, community fellows and collaborators), and we are in the process of building this collection in collaboration with representatives of Brown's Center for Digital Scholarship and the Brown Library's digital repository service. We have also begun assembling a database of texts (books, journal articles, grant application guidelines, blog posts, and the language of Center / program recruitment literature, among others) to better understand where and why the phrase "public humanities" has been utilized between the late twentieth century (starting around 1970, in Congressional documents that informed the creation of the NEH) and the early twenty-first century. The poster will contextualize the motivations behind our decisions to focus on particular corpora and the organization of our database. Beyond the first iteration of this hyperlocal history (which will materialize in the form of the first stage of the Center's collection in Brown's digital repository and will be publicly available to researchers), we will concurrently release a dataset of public humanities corpora and a series of visualizations exploring that data. One will begin to map the geographic regions and institutional ties to public humanities programs and grant-funded public humanities initiatives. Another will document part of the citational history of public humanities discourse by visualizing links between texts present in bibliographic data of a sample set of academic texts. Representative samples of these visualizations, which are not meant to be comprehensive so much as they are intended to be models for potential avenues of inquiry, as well as the methodologies informing them, will be featured in the poster. We will also link these datasets to the crowdsourced data we receive from "Day of Public Humanities" (#DayofPH), a digital project held in May of 2017 that, like the "Day of Digital Humanities" initiative, aims to make the various forms of day-to-day labor (and laborers) in the field visible and to encourage dialogue across and beyond these contexts.

This poster will reflect on the Association of Research Libraries' (ARL) upcoming inaugural week-long Digital Scholarship Institute for library professionals. Scheduled for June 2017 at Boston College, the Institute will introduce librarians and staff who are not currently involved in digital scholarship to the methodologies and considerations of such work. This poster will detail successes and lessons learned for future Institutes.

Following two large-scale workshops hosted by the Coalition for Networked Information (CNI) on planning and supporting digital scholarship centers in 2014 and 2016, staffing and training emerged as fundamental components to successful initiatives. In 2014, workshop participants agreed that:

> *"...it is more important to have the proper mix of abilities overall across personnel than it is to have any one particular type of staff member. The ability to learn new skills, adaptability, and agility are qualities in personnel that can be even more important than the expertise that they initially bring to the position."* (Lippincott and Goldenberg-Hart, 2014:7)

In 2016, CNI hosted a follow-up workshop in partnership with ARL with over 100 participants. The resulting report from that meeting made it clear that *people* are core to the success of digital scholarship initiatives. Several points of consensus emerged from the 2016 workshop, two of which ARL has adopted for the Digital Scholarship Institute:

- Staff need time including time for research, space, recognition, and funding for intensive professional development, and the freedom and ability to develop library digital projects
- Skill-building goes beyond workshops and collaborations, and is often rooted in culture change and support from administration (Goldenberg-Hart, 2016.)

In response to these discussions, the ARL Digital Scholarship Institute Advisory Group identified several core principles that underpin digital scholarship initiatives with an emphasis on cultural change: collaboration, critical thinking, and disciplinary contexts. Rather than starting with tools or technologies, the Institute emphasizes these concepts as building blocks of digital scholarship.

By providing a five day, face-to-face immersive environment, the Institute will cultivate collaboration and create cohorts of digital scholarship practitioners. These cohorts will learn together, share experiences, and work on future endeavors through follow-up online meetings that will ensure participants have opportunities to put core principles into practice. Participants will learn core principles related to metadata and data curation, copyright and fair use, and project management. They will also learn how to apply these concepts in the context of digital pedagogy and collaboration with researchers. These applications build on existing librarian skillsets related to instruction and to work with researchers needing to clarify and refine research ideas. The framework of the Digital Scholarship Institute thus bridges existing library capacities with new knowledge and skills that will transform their work as they increasingly partner with researchers on digital scholarship using diverse digital methods and tools.

The ARL Digital Scholarship Institute also builds on the University of Rochester's pilot Institute for Mid-Career Librarians in Digital Humanities funded by the Andrew W. Mellon Foundation. The program invited twenty librarians from across the US and Canada to take part in a three-day intensive residential institute followed by monthly online meet-ups from July 2015-June 2016.

The pilot successfully built a strong cohort among the attendees, who were assigned to one of four curriculum tracks based on their interests: text encoding, analysis and visualization; digital pedagogy and digital media literacy; digital mapping and archeology; and metadata, data curation, and data modeling. A core curriculum included workshops on project management, data modeling, and copyright/fair use. Objectives of the pilot institute included strengthening librarian practice to support digital humanities, creating a structure to support sustained skills development, and integrating with future ARL initiatives.

Attendees participated in assessment activities throughout the year-long pilot, providing data to inform the creation of sustainable programs. In October 2016 teams from five institutions, University of Rochester, Indiana University, University of Illinois at Urbana-Champaign, San Diego State University, and Boston College, met to workshop the creation of a program that would be foundational to creating these new communities of practice. This multi-institutional initiative will provide an opportunity for broader transformation in the academic library ecosystem at the level necessary to create a strong community of practice around digital scholarship work.

Introduction

EGO (European History Online) is a transcultural history of Europe on the Internet published by the Leibniz Institute of European History. The success and the consequential growth of EGO is, however, a challenge for the editorial office. The interlinking of EGO articles with each other and with external resources is an important aspect of EGO's conceptual design, so each new article has to be integrated into the existing link structure. This means not only that the new article has to be linked to relevant existing articles or online sources, but the copy editors must also check whether links to the new article need to be added to existing articles.

Doing the linking manually is a tedious task. Therefore, we aim in the EGOlink project at developing methods for (semi-)automatically linking EGO articles in order to reduce the manual effort for the editorial office and to improve the navigation for readers.

As a first step, we present a tool for visualizing and analyzing the current link structure in EGO document collection. Besides detecting problems such as under-linked articles, the analysis tool provides information that is needed by a (semi-) automatic linking system. In the next step, the automatic generation of links is addressed; the two main research questions here are: (1) the automatic identification and ranking of potential link anchors in EGO articles, and (2) the discovery of suitable link targets in other EGO articles or external resources.

Background

EGO Document Collection

EGO provides a platform for publishing refereed academic articles about the history of Europe with a special focus on modern Europe from the end of the Middle Ages up to contemporary history. EGO is bilingual, i.e., it contains articles in English and German. Most articles written in one language are translated into the other language and published in both languages. Currently, EGO contains 670 articles: 436 in German and 234 in English.

Linking articles to each other as well as to external resources is a major focus of EGO. Once a new article is submitted the editorial staff put a special effort on linking the articles to already existing EGO articles as well as to other resources or multi-media contents, such as images, interactive maps, video and audio clips.

Entity Linking

As already mentioned, linking articles is at the heart of EGO. So far, this task has been done manually. We aim to optimize this process by developing a (semi-)automatic linking tool based on state-of-the-art approaches while taking the peculiarities of EGO into account.

The problem of (semi-)automatically linking EGO articles to each other or to external resources can be modeled as link discovery, or entity linking (Larson, 2010). In general, entity linking consists of two main steps (Erbs et al, 2011): 1) anchor discovery, which identifies text mentions that can function as link anchors, and 2) target discovery which identifies the best matching references for each anchor from a set of candidates. While anchor discovery can be handled independently of the document collection at hand – e.g. using NER (Named Entity Recognition) (Nadeau et al, 2007) or keyphrase extraction methods (Turney, 2000), discovering and ranking the targets are much affected by the nature of the document collection.

Currently, several state-of-the-art algorithms for entity linking have been made available (Hoffart et al, 2011) (Ceccarelli et al, 2013). However, applying such algorithms directly to perform entity linking based on EGO is challenging. In general, current algorithms rely on extracting statistics about candidate entities, e.g., popularity-based priors; form a huge corpus like Wikipedia. The priors are then used during the process of the target discovery and ranking. However, such an approach is not applicable in our case due to the tiny size of EGO compared to other similar resources like Wikipedia. Another challenge is posed by the German part of EGO. Current approaches focus on English and a special effort should be made to address entity linking for German.

Erbs et al (2011) demonstrated that approaches for target ranking that leverage the linking structure available in the document collection perform best compared to other methods that only leverage the titles of the documents or the associated texts. In light of this result, we propose a tool for analyzing the linking structure in EGO's document collection. The proposed tool helps us to understand the current status of EGO's links and to gain insight regarding the decisions that should be taken to develop the actual entity linking system. Besides identifying links among the articles, the proposed tool also extracts information from an additional resource, namely the literature referenced by the articles. Our hypothesis is that articles sharing the same reference should be linked to each other. As a result, this kind of analysis can help the (semi-) automatic linking system to identify further anchors, thus the interlinking density of the document collection can be increased.

EGO Analyzer

EGO Analyzer is a web-based analysis tool for EGO document collection. The tool can handle the English as well as the German parts of EGO jointly or separately. Since EGO's articles exist in XML format, the tool was built to work on XML data directly and efficiently using the high-performance and scalable XML Database engine BaseX. Besides providing different kinds of metadata about EGO's articles, the tool allows analyzing EGO from different perspectives: the corpus, the article and the reference perspectives (Figure 1).

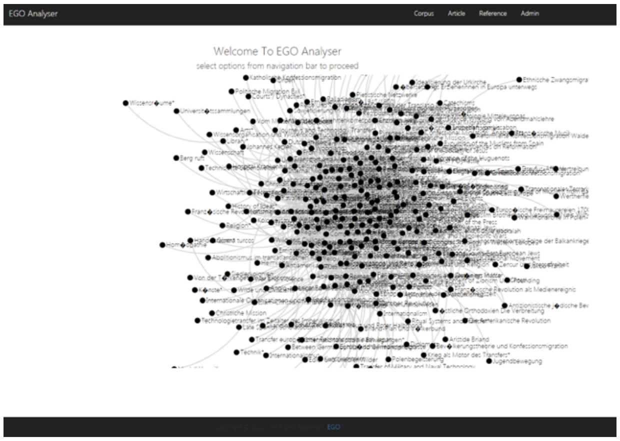

Figure 1. Screenshot: EGO Analyzer

For instance, given the article titled “Kulturtransfer” from the German collection, the tool extracts links to other articles in both directions, i.e., outgoing as well as incoming links (Figure 2). Furthermore, we can view the set of articles that reference the same bibliographical entries as the source article (Table 1).

Eine transkulturelle Geschichte Europas – migrationsgeschichtliche Perspektiven	2
Europäisierungen	2

Table 1. Articles sharing bibliographical entries with the source article “Kulturtransfer”

Results of the Analysis

Using EGO Analyzer we collected statistics about the linking structure in EGO. We divided the links into two categories: internal and external. Internal links point from one EGO article to another, while external links refer to external targets. For each article, we also distinguish between two types of links: incoming and outgoing links. Figure 3 shows the average number of internal/external as well as incoming/outgoing links per article.

The results show that dominance of the external links (3 times as much as internal links). This can be explained due to the relatively small size of the document collection. Accordingly, it is hard for the editors to find corresponding internal links for entities in a newly added article. Moreover, this also explains the higher number of outgoing links per article. Indeed, most of these links go to external resources which are not necessarily linked back to EGO articles. This observation demonstrates the urgent need for an automatic linking system that enables the editors to increase the interconnectivity of EGO.

Furthermore, the linking tool can also run as a background process that updates the linking structure of EGO every time a new article is added.

Regarding the shared bibliography, we identified 13,309 unique references, 737 of them are referenced by at least two articles. We will use this kind of information as auxiliary input for the linking algorithm to identify additional linking candidates.

	Internal	External	Incoming	Outgoing
🟦 German	14.47	44.82	10.22	49.08
🟥 Englsih	18.79	71.87	13.35	77.31

Figure 3: Average number of links per article and category

Conclusion

In this abstract, we presented work in progress for assisting editors of EGO to (semi-)automatically link the articles. We focused on the first step towards such a system, namely, analyzing the link structure in the target document collection. We presented a web-based tool that is able to perform such analysis. Currently, we are working on the actual linking system as well as a user-friendly interface for the editorial office. By the time of the conference, we will also provide a demonstration of the actual linking tool.

Seven Years of Research on Digital 3D Reconstruction in Humanities – Results, Implications and Perspectives

Sander Münster
sander.muenster@tu-dresden.de
Technische Universität Dresden, Germany

Abstract

Since an academic discourse on using digital 3D reconstruction tools for humanities research is still highly application-oriented, an overarching objective of our research work is to draw a currently missing “big picture” on digital 3D reconstruction as a research tool in digital humanities by combining theoretically and practically grounded research parts as well as including multi-disciplinary perspectives. This article provides an overview of research work carried out by our department in 12 projects over the past seven years, namely on (a) scenarios and practices for the employment of digital 3D reconstruction and visualization methods and approaches for scientific research in visual humanities, (b) requirements and recommendations for digital tools, and (c) approaches to teach digital 3D reconstruction methods at university. The article is intended to contribute to a comprehensive discourse on a unique epistemology of digital 3D reconstruction in humanities and to deliver related practically tested implications for software de-sign, teaching and organizational settings.

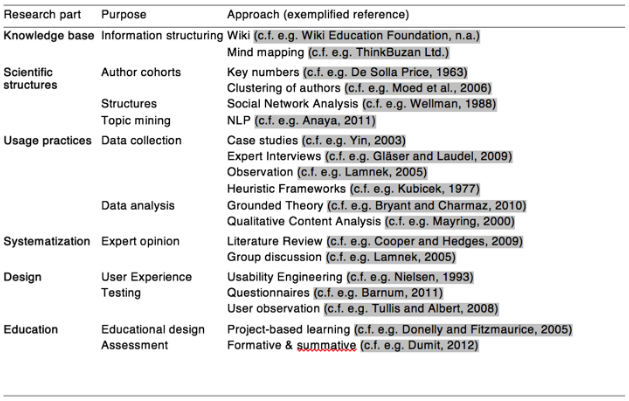
Introduction

For more than 30 years, digital 3D modelling and in particular reconstruction methods have been widely used to support research and education in the digital humanities, especially but not exclusively on historical architecture. While technological backgrounds, project opportunities, and methodological considerations for the ap-plication of digital 3D reconstruction tech-niques are widely discussed in literature (e.g. Arnold and Geser, 2008, European Commission, 2011, Frischer, 2008, Bentkowska-Kafel et al., 2012, Bentkowska-Kafel, 2013, Kohle, 2013), our interest is to investigate digital 3D reconstruction as a scholarly area and to derive implications for further organizational and methodical development. Against this background, this research work is dedicated to support the dissemination process by investigating the following research questions:

- What scenarios and practices exist for the employment of digital methods and approaches for scientific research within the field of digital 3D reconstruction, especially in art and architectural history?
- What are requirements and recommendations for the design of tools and media related to digital 3D re-construction?
- How can the use of digital methods and, in particular, digital 3D reconstruction techniques in visual human-ities be learned and taught?

Research

Against the background of these research interests, our research activities include to investigate (1) a scholarly community, (2) usage practices occurring with-in single projects and to gain implications for an appropriate organizational development. Moreover, practical application and a development of implications for (4) the conception and creation of a user-centered design of software tools and environments for digital humanities scholars and an (5) implementation in student education are in focus. Research methods and approaches used within the described research activity mainly derive from social and information sciences as well as from science and technology studies (cf. Hackett et al., 2008, Boczkowski and Lievrouw, 2008, pp. 955) and comprise e.g. bibliometric analysis (cf. Vinkler, 1996), quantitative and qualitative empirical analysis as well as structuring approaches like mind mapping (Table 1). Relevant research has been active since 2010 in 12 projects (ongoing till approx. 2020) on the local, national and EU levels, with our department’s participation.



Research part	Purpose	Approach (exemplified reference)
Knowledge base	Information structuring	Wiki (c.f. e.g. Wiki Education Foundation, n.a.) Mind mapping (c.f. e.g. ThinkBuzan Ltd.)

	Assessment	Formative & summative (c.f. e.g. Dumit, 2012)

Table 1. Brief overview of methodical approaches

Results

Considering a scholarly community on digital 3D reconstruction and modeling, discourses on major conferences during the last 25 years were mainly led by institutions from European Mediterranean countries, covering primarily technological topics. In particular, statues and buildings in Mediterranean countries dating from all periods Anno Domini deliver rich content for such reconstruction (Fig. 1). Institutions with high numbers of publications, connections to co-authors or the extraordinary importance to link groups of researchers to each other can be identified on a structural level (cf. Fig. 2). Due to the high complexity and team based workflows, aspects and usage practices for communication, cooperation, and quality management are of high relevance within 3D reconstruction projects. Especially if people with different disciplinary backgrounds are involved, visual media are intensively used to foster communication and quality negotiations (cf. Fig. 3), for example by comparing source images and renderings of the created virtual reconstruction. Furthermore, several projects successfully adopted highly standardized conventions from architectural drawings for interdisciplinary exchange (Münster, 2013). To support an organizational development, we ran five workshops to identify ongoing research topics and challenges, involving around 100 researchers in total. Current challenges named (cf. Fig. 4) aim at a research and development of sustainable and practicable approaches to access wider scientific communities and audiences and include aspects such as widely interoperable documentation and classification strategies and schemes, an overarching cataloguing of projects, and the creation of objects as well as strategies and technologies for an exchange between different technological domains and approaches of usage. Regarding design implications for digital environments, we investigated, for example, that relatively little visual information is needed to allow observers to distinguish buildings from each other or to identify a single building and gain information about its spatial relation and shape (Münster et al., 2017b). Moreover, we adopted and evaluated team project-based learning approaches to support student education in digital 3D reconstruction (cf. Fig. 6). As observed in two courses so far, a development of procedures and strategies for cooperation within student project teams for creating virtual representations evolves slowly and is mostly caused by emerging problems and urgent demands. Related competencies are based highly on implicit knowledge and experience. As a consequence, a teaching of implications and best practices prior to commencing a project is less effective than coaching during the project work.

Summary

Since it is our vision to establish digital 3D reconstruction as a scholarly accepted and widely used research method in humanities, it seems to be crucial to add a critically reflected methodological basis and anchor it in academic culture. To draw this currently missing "big picture", our department performed research on digital 3D reconstruction within various projects by combining both theoretically and practically grounded research parts. This comprises research on scholarly communities, scholarly practices and methodological recommendations as well as implications for interaction design, teaching and dissemination.

Introduction

This paper describes a collaborative approach of information exchange between art history and literature via IIIF as conducted by two projects: the SAT Daizōkyō Text Database Committee (SAT) and a project to leverage an open dataset of the National Institute of Japanese Literature. This approach is technically similar to that used by previous projects such as TILE and TEI. However, as it has not been easy for them to fully treat the binding of images of a book between Web services, this approach adopts the IIIF (International Image Interoperability Framework) so that both can connect easily and efficiently. After explaining the distinctive aspects of both projects, we will introduce a collaborative solution.

In May 2016, SAT released the SAT Taishōzō Image DB (SATiDB), which includes digital facsimiles of a series of Buddhist images and their interpretations in the Taishō Tripitaka consisting of 12 volumes originally published in 1933. SATiDB provides annotations for about 5,200 Buddhist icons (*busson*) and symbols (*sanmayagyō* and mandala) in the books and several search functions of the annotations with a simple translator from English to technical terms in CJK characters via the Digital Dictionary of Buddhism. As the annotations use a vocabulary of attributes of Buddhist icons, such as hair style, sitting style, type of chair, possessions, etc., which was defined by this project due to the absence of such a vocabulary in the source data, users can also search the objects by clicking a checkbox of one or more term in a list form of the vocabulary (Figure 1).

Figure 2. Checked images are displayed in parallel.

The annotations were embedded by forty-three researchers in the field of Japanese art history on a web collaboration system in 2015. We developed the system utilizing RedHat Linux, Apache, PostgreSQL, PHP, jQuery, and Annotorious, which enabled the easy annotation of images. The annotations were stored in PostgreSQL including attributes such as date and responsibility. After input, the data were converted into IIIF Presentation API and distributed with hi-resolution images converted from 60M-pixel images delivered with IIIF Image API. This system provides researchers of Japanese art history with a brand new function to see and compare Buddhist icons and symbols. Many positive comments have been received from the researchers of Japanese art history and the number of visitors of the site was over 12,000 in the first month, but no papers have yet been produced explicitly using this system.

The other project also developed a Web collaboration system to embed transcription of Japanese texts (the issues of such transcription have been described by Nagasaki et al, 2016) line-by-line in the style of IIIF annotation which enables to search images as-they-are via Smart-GS. (Hashimoto et al, 2014) It adopts OpenSeaDragon and its plugins to annotate images with zooming and has a function to convert them into the format of IIIF Presentation API. So far, two pre-modern woodcut printing books written in cursive Japanese script were completely done by two researchers and available via customized Mirador for right-to-left viewing-direction and vertical texts (Figure 3).

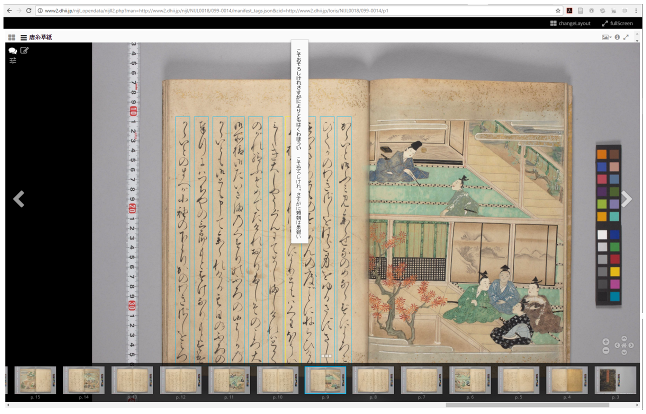

Figure 3. Customized Mirador for right-to-left viewing-direction and vertical texts

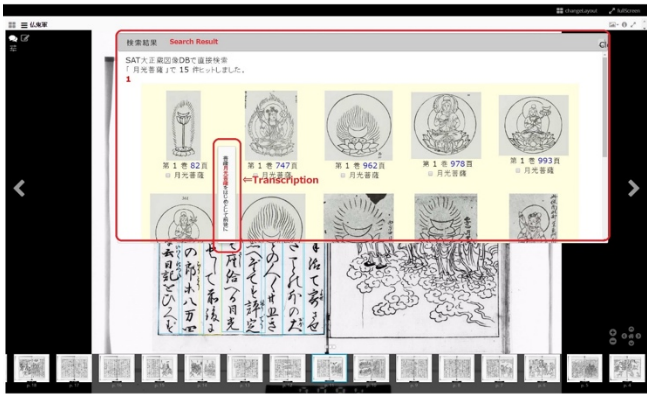
Finally, we explain the approach of linking both projects. As one of the two transcribed woodcut printing books includes names of Buddhist saints, we added tags on the names to trigger an event to search the name and prepare a function to request queries to the SATiDB. On the other hand, in the SATiDB, a function to distribute only a list of search results including images cropped by IIIF Image API was implemented to pull search results from other Web sites by use of a form of URL such as:
http://dzkimgs.l.u-tokyo.ac.jp/SATi/key:_*keyword*_



SAT大正蔵図像DBで直接検索
「 月光菩薩 」で 15 件ヒットしました。

Figure 4. Search result of SATiDB by clicking a red-colored part of transcribed text

As a result, readers– primarily researchers, but laypersons as well– can see images of related Buddhist icons on SATiDB while reading the book. See Figure 4 to understand background of it. This is a typical solution of IIIF and easily applicable for any environment in the digital humanities.

Introduction

The World Wide Web provides the research community with an unprecedented abundance of primary sources for diachronically tracing, examining and understanding major events and transformations in our society (such as the rise of euroscepticism or the impact of the recent economic crisis). For two decades, public and private institutions have preserved these born-digital materials for future analysis (Gomes and Costa, 2011). However, these collections are now so large that it is infeasible for researchers to study political and social phenomena by examining them in their entirety.

Creating event collections. A common solution that web archives are currently adopting for sustaining the use of the collected sources in humanities research is to offer topic-specific collections. For example, on Archive-it, the Internet Archive presents a few collections on large-scale events such as the Boston Marathon Bombing, Black Lives Matter and the Charlie Hebdo terrorist attack. The collections are curated "by the Archive-It team in conjunction with curators and subject matter experts from institutions around the world" .

Another solution for creating event collections from large datasets is a filtering approach that collects only documents that mention the name of the event; this method has been employed for example in temporal summarization tasks (see Aslam et al., 2013).

Current limitations. The collections created following one of these two approaches share crucial limitations: a) they are small in number; b) the selection process is not always transparent; c) they generally offer only documents that are closely related to an event but lack information on background stories as well as contextual clues. Especially the latter is a crucial issue for historical analyses.

Our vision. We are currently developing a solution for creating event collections that identifies not only the core documents related to the event itself, but most importantly sub-groups of documents which describe related aspects. We do so through an expansion process that is informed by latently relevant concepts and entities from a knowledge base, whose presence in documents is interpreted as one of many indicators of relevance.

Specific contribution. At the DH conference we intend to present the final results of our study, together with its application for supporting research in political and social history.

Method

Let us consider an event, for example the Syrian Civil War, as a node in a knowledge graph (e.g. DBpedia).

As a first step, a domain expert will identify a series of other entities in the knowledge graph that are highly related to the event (in Nanni et al., 2016, we show that this step could be automatized adopting a simple relatedness measure). These could be people, such as Bashar Al-Assad as well as countries (e.g. Turkey, Russia, United States), concepts (e.g. Protests) and other specific events (e.g. The Refugee Crisis). These initial seeds will support us in retrieving other related entities and concepts from the knowledge graph in an automated fashion (we described our solution in Nanni et al. 2016).

While retrieving related entities is important, these are meaningless without human-readable descriptions of the entity's relation to the event. As a matter of fact, the entity United States has many different aspects, and only few of them are related to the event Syrian Civil War.

In order to retrieve entities in context, we use Wikipedia as an initial corpus. Next, relevant passages from the documents are identified in the collection by information retrieval. Having the entity in context will tell us with which words, concepts and other entities it frequently appears together (a complete overview of the method is presented in Nanni et al., 2017). For example, if a document mentions the United States together with James Foley and ISIS, it is likely to be related to the Syrian Civil War, even without mentioning these words explicitly.

Case studies

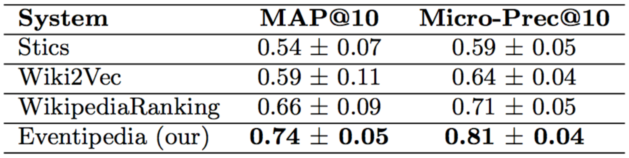
We are currently working on two different research tasks:

1. The first study is focused on identifying political speeches on foreign events (such as elections in other countries) in the US Congressional Records (1989-2016), which are available on Congress.gov and through the Internet Archive (Congress.gov provides full-text access to daily congressional record issues dating from 1995, beginning with the 104th Congress. Proceedings for previous years are available on THOMAS). The goal is to measure the amount of attention that US politicians give to international events in correlation with other internal affairs.

2. In the second study, we intend to detect similar patterns during the early rise of anti-establishment protests. Our aim is to uncover small events, which did not turn into large-scale insurrections and therefore are not studied sufficiently. The work is conducted on a large (16 terabyte) web archive of news, blogs, forums and social media, namely the TREC Streaming Corpus (This corpus is a huge web archive collection collected between 2012 and 2014). Finally, the goal of the project is to obtain a better understanding on how and why specific protests succeed while others do not (also in correlation with analyses from the previous study).

Experiments

Identifying related entities. In a previous work (Nanni et al., 2016), we have first established the quality of our entity-relatedness solution (Eventipedia), by comparing it with a series of other baselines commonly used in the field. The results are reported in Figure 1.



System	MAP@10	Micro-Prec@10
Stics	0.54 ± 0.07	0.59 ± 0.05
Wiki2Vec	0.59 ± 0.11	0.64 ± 0.04
WikipediaRanking	0.66 ± 0.09	0.71 ± 0.05
Eventipedia (our)	**0.74** ± **0.05**	**0.81** ± **0.04**

Figure 1. Evaluation on entity-event relatedness (from Nanni et al., 2016).

While our entity-relatedness solution outperformed the other tested methods, it also showed a few limitations. In fact, this approach (in its fully automated fashion) tends to privilege specific entities over the most commonly mentioned entities. We address this in developing techniques that are supervised by domain experts; this ensures us to always consider the most relevant related entities.

Collect entities in context. Additionally we studied the identification of human-readable descriptions of the entity's connection to the event. We compared our entity link-based approach with a common information retrieval heuristic which considers the first sentences of the entity's Wikipedia article, as a relevant passage (Wiki-Intro).

		Eventipedia Snippet			
		Rel.	Non-Rel.	Missing	∑
Wiki-Intro	Relevant	85	10	80	175
	Non-Rel.	180	5	31	216
	∑	265	15	111	

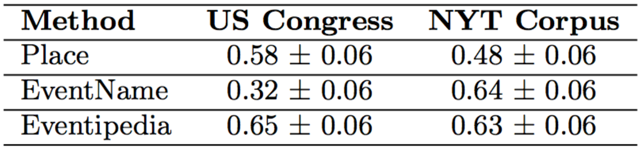
Figure 2. Evaluation on retrieving entities in context (from Nanni et al., 2016).

The results are presented in Figure 2. In 45% of the cases, the Wiki-Intro was a sufficient explanation. However, our Eventipedia approach provides sufficient explanations in 68% of the cases. We remark that for nearly all cases, where Eventipedia does provide a snippet, this is also relevant. In contrast, the Wiki-Intro only provides a good explanation in 42% of the cases. This is because many event-relevant entities (e.g. the United States) are often more popularly known for other accomplishments and therefore the first paragraph is not a good description of entity involvement in the event.

Retrieve relevant documents. We are currently assessing the quality of our information retrieval solution, which uses entities and contextual passages to retrieve documents about specific events with an approach based on Dalton et al. (2014). We report here the very first results of our study on retrieving speeches about foreign elections. This work has been conducted both on the US Congressional Records on the New York Times Corpus.

We compared it with two baselines, a) retrieving all documents that mention the name of the country (e.g. "Syria") and b) retrieving all documents that precisely mention the name of the event (e.g. "election in Syria"). It is evident that the first solution is recall-oriented, while the second, already adopted by the TREC temporal summarization task, favors precision.

Given an event, such as the Syrian presidential election, 2007, all three methods produce a ranking of documents. We examine the quality of the ranking considering 15 different elections. For each election, we created a gold standard of 45 documents (relevant and non relevant). Table 1 presents the results in term of mean-average precision (MAP) on the two datasets.



Method	US Congress	NYT Corpus
Place	0.58 ± 0.06	0.48 ± 0.06
EventName	0.32 ± 0.06	0.64 ± 0.06
Eventipedia	0.65 ± 0.06	0.63 ± 0.06

Table 1. First results (MAP) on the collection-building task.

The results of this initial study lead to a few findings. First we see that, especially on the US Congressional Records, using the name of the event permits to collect a fraction of relevant documents, but not all of them. Second, our solution, which uses related entities in context, provides good performance quality on both datasets. Third, our solution is able to identify materials that do not explicitly mention the name of the event.

"Non-relevant" documents. We next analyze what kind of "non-relevant" documents the different systems retrieved among the top elements of the ranking. Non-relevant documents retrieved by the "Event name" solution often discuss different topics and simply mention the event out of context; these documents could be for example general summaries of the previous week.

Instead, non-relevant documents retrieved by Eventipedia are often related to the political activity of a foreign country, but not specifically about the election. For example, they could mention the visit of a candidate to Washington, a few months before the vote. It is evident that choosing one method over the other will shape the event-collection in a different way. Ultimately, it is up to the humanities researcher to decide which documents are most important for the analysis.

Enhancing Domain-Specific Entity Linking in DH

Federico Nanni

dietz@cs.unh.edu
University of New Hampshire, United States of America

For the purpose of information retrieval and text exploration, digital humanities (DH) scholars have examined the potential of methods such as keyphrase extraction (Hasan and Ng, 2014) and named entity recognition (Nadeau and Sekine, 2007). However, these solutions still face challenges in the presence of polysemy and synonymy (e.g. distinguish between “Paris” the capital of France or the city in Ontario or recognize that “POTUS” and “Barack Obama” might refer to the same person).

Entity Linking

In the last decade, advances in natural language processing (NLP) gave rise to word-sense disambiguation and entity linking techniques (Cornolti et al., 2013), which automatically disambiguate entities and concepts in context and link them to knowledge bases such as Wikipedia, DBpedia (Auer et al., 2007) or Babelnet (Navigli and Ponzetto, 2012). Among them, TagMe (Ferragina and Scaiella, 2010) has been often adopted in NLP, thanks to its decent performance on different datasets and to its easy-to-use API.

Current Limitations for DH research

TagMe also highlights a few common limitations of current standard entity linking systems that reduce their applicability within most scenarios found in the heterogeneous spectrum of Digital Humanities research.

- **Black Box and reproducibility.** As Hasibi et al. (2016) recently remarked, the TagMe RESTful API remains a black box, as it is impossible to check whether it corresponds to the system described in the original paper. Not knowing the reliability of the system limits its use for distant reading analyses, i.e. quantitative studies that go beyond text exploration.
- **Language Versions.** Currently, TagMe is only available in English, German and Italian but does not support other widespread languages such as Chinese, Arabic, Spanish, and French, which are essential for enhancing its use in the DH community.
- **Infrequent Updates.** TagMe has been initially created on the English 2009 version of Wikipedia and it has been updated only twice (summer 2012, summer 2016). Imagine a setting where a scholar intends to analyze a collection of mainstream news on the Middle East: before the most recent update the system was not able to detect mentions of “Al-Nursa Front”, the former Syrian branch of al-Qaeda.
- **Wikipedia as Knowledge Base.** TagMe, as well as other entity-linking solutions, relies on the assumption that the entries and structure of Wikipedia provide us with a comprehensive and accurate knowledge base. While this is mostly true for standard NLP and IR approaches, when it comes to humanities research this assumption shows all its limitations. As a matter of fact, linking to Wikipedia is not ideal for example when dealing with historical documents, simply because entities and concepts relevant in the corpus may be missing from such a general-purpose knowledge resource (as remarked in Lauscher et al., 2016).

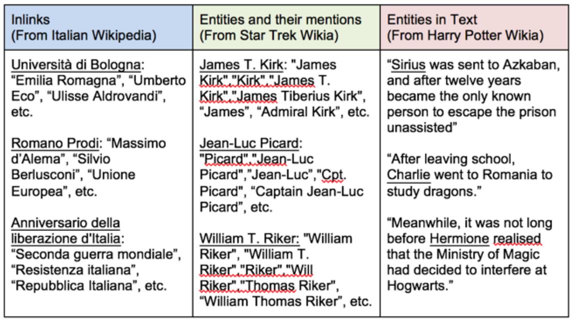
Specific contribution

While we are currently working on the implementation and optimization of a domain-adaptable entity linking pipeline, at the conference we intend to present a solution for generating, in an automatic fashion, domain-specific knowledge bases from an user-created Wiki. As the creation of a complete Wiki is too time-consuming, these domain-specific wikis are used in combination with general world knowledge available on Wikipedia. In particular, we will describe how our system can make use of the following input:

The XML Dump of any language version of Wikipedia and rapidly create the indexes that compose the knowledge base. This permits to have a knowledge base for each language version of Wikipedia and to update it on the spot whenever needed.

Any MediaWiki website dump, such as Wikia (although it is important to consider the copyright license when downloading and using this data), to be merged into the same index. In the table we report a few examples from different Wikia sites. It is important

This solution gives the scholar the possibility of creating (or improving an already existent) domain specific Wikia (a practice common in DH education, see Farabaugh, 2007 and Giglio & Venecek, 2009) on the topic she/he intends to study and identifying mentions of domain-specific and general-purpose concepts in large text collections.



Inlinks (From Italian Wikipedia)	Entities and their mentions (From Star Trek Wikia)	Entities in Text (From Harry Potter Wikia)

Text Mining Eighteenth-Century Travel Writing: The "I" and Autobiography of Narration

Catherine Nygren
catherine.nygren@mail.mcgill.ca
McGill University, Canada

How can text mining further explore and challenge our conception of how the style of British travel writing changed from 1700 to 1830? In this poster, drawn from the first chapter of my dissertation, I use text mining methods to explore the purported coming forth of the self in eighteenth-century travel writing, examining texts ranging from instructions for gentlemen and antiquarian accounts to the documents of New World explorers and the journals of female travelers. Increasing public demand for travel-related texts and the genre's potential for experimenting and examining social, philosophical, and aesthetic ideas elevated travel literature to one of the most important - and popular - genres of the century. Despite the modern broadening of the definition of travel literature and analyses that use the lenses of feminism and postcolonialism, however, overviews of travel writing still primarily use close readings and representative samples of texts to make claims about the genre as a whole.

My project, however, will use a corpus of more than 3500 texts (curated through a combination of existing bibliographies and machine learning methods) to examine and challenge our received literary histories of the genre. In particular, this presentation focuses on the "I" and autobiography in narration. In the first half of the eighteenth century, authors crafted travel texts to have a balanced amount of personal narration: the voice of the narrator was required to provide order, entertainment, and authority in the narrative, but with an over-emphatic voice, the author would appear egotistical, fantastical, and unreliable. By the middle of the century, however, scholars identify a trend of authors increasingly writing in a first-person voice and interpolating their detached, factual observations with their personal experiences and reflections. Around the turn of the century, when many locations, particularly Grand Tour destinations like France and Italy, had been described multiple times, readers desired more original writing and critics used personal narration as evidence that the author had actually travelled. Still, authors often felt they had to justify writing in a distinctive voice: Mary Wollstonecraft, when she found she could not "avoid being continually the first person—'the little hero of each tale,'" became "determined to let [her] remarks and reflections flow unrestrained" (3).

In this poster, therefore, I seek to examine this purported coming forth of the self in eighteenth-century travel literature. Tracking distributions of pronouns, such as “I,” “me,” and “you,” and other narrative signifiers will reveal the shifting trends of personal narration in my corpus. Analyzing the words used in titles—such as “Observations,” “Reflections,” and epistolary markers, among others—may provide further insight into how authors and publishers conceptualized and marketed the relationship between the author, the narrator, and the reading public. In examining such patterns, I seek to answer questions such as whether the pieces we consider more “literary” use the first-person voice more often or more experimentally, whether particular sub-genres or texts in my corpus are more likely than others to follow this trend, and whether any other shifts in grammar and vocabulary accompanied this new privileging of first-person narration. A corollary question is whether Sterne’s *Sentimental Journey* is, as several critics contend, truly a catalyst for this trend, and how the influence of Sterne and other significant authors manifest in my corpus. In particular, I will pay close attention to female writers and authors of colour, following the work of critics such as Elizabeth Bohls, in order to see how they subvert and support the trends of travel writing at that time.

This first chapter on the self, along with my dissertation’s examinations of descriptive language and subgenre, will provide an extensive understanding of eighteenth-century British travel writing. My approach encourages both breadth and depth in subject material, from patterns across hundreds of texts to significant paragraphs, sentences and words. This mixture of distant and close reading will offer a reformulation of the massive genre by, for the first time, analyzing a significantly larger corpus than was previously possible. My findings and methodology (shared through Github and other public forums) will provide critical resources and frameworks for future investigations of the language and genre of other forms of eighteenth-century literatures.

Construction of the “Corpus of Historical Japanese: Meiji–Taishō Series I – Magazines”

Toshinobu Ogiso
togiso@ninjal.ac.jp
National Institute for Japanese Language and Linguistics
Japan

Asuko Kondo
kondo@ninjal.ac.jp
National Institute for Japanese Language and Linguistics
Japan

Yoko Mabuchi
mabuchi@meiji.ac.jp
Meiji University, Japan

Noriko Hattori
nhattori@ninjal.ac.jp
National Institute for Japanese Language and Linguistics
Japan

In this talk, we wish to discuss the construction of the corpus “Meiji-Taishō Series I - Magazines,” (hereinafter called CHJ-Magazines) which was released as a part of the Corpus of Historical Japanese (CHJ). This corpus contains magazines published in Japan in the Meiji and Taishō periods (1868–1911) representative of Modern Japanese language, with the total number of words used in the text reaching a size of some 14,000,000 items. This corpus is the first large-scale corpus with morphological information of Modern Japanese and will contribute to research into that period of the Japanese language.

At the National Institute for Japanese Language and Linguistics, a joint research project entitled “Construction of a Diachronic Corpus and New Developments in Research of the Japanese Language” was begun in 2016. CHJ Magazines is one part of this project, using a number of representative magazines for each of several periods, with the selected published material spread out over set time intervals. The result is a large-scale corpus that makes it possible to examine the state of the written Japanese language in the Meiji and Taishō periods, as well as to examine how the language underwent changes in those periods (Table 1).

	1870’s	1880’s	1890’s	1900’s	1910’s	1920’s	*Total*
“Meiroku Zasshi”	180						*180*
“Kokumin no Tomo”		1,000					*1,000*
“Taiyo”			2,280	4,300	2,050	2,300	*10,930*
“Jogaku Zasshi”			680				*1,890*
“Jogaku Sekai”				590			
“Fujin Kurabu”						620	
Total	*180*	*1,000*	*2,960*	*4,890*	*2,050*	*2,920*	*14,000*

Table 1. Corpus Size for Each Year of Publication (Units: Thousand Words)

One characteristic of this corpus is that morphological (word) information is annotated to each text. In order to annotate highly accurate morphological information to the corpus, it was necessary to develop and utilize a dictionary that could enable automatic morphological analysis for the colloquial and literary styles that was mixed in the written Japanese of the aforementioned periods. We customized UniDic, a dictionary for morphological analysis of Japanese, which can lemmatize variations of orthography and word forms. We also used MeCab, a state-of-the-art Japanese morphological analyzer with this customized UniDic.

While the accuracy of automatic analysis is high at approximately 93%, it is extremely difficult to append morphological information uniformly without any mistakes in such a large amount of text. To address this difficulty, it was necessary to establish a "core" data set, for which we could guarantee the attachment of highly accurate morphological information (with accuracy higher than 99%) through the utilization of automatic computer analysis together with manual (human) correction. For core data, 500,000 words were selected, taking into consideration the balance of publication year, style and genre of each of the articles sampled. Core data is suitable for Japanese research which requires highly accurate morphological information. This data was also used as training data for the dictionary for morphological analysis described above. The automatic analysis results of the "non-core" data set, meanwhile, received a certain degree of manual correction which, while not being exhaustive, strikes a balance between quality and volume.

This corpus is made publicly accessible by way of an online search application called "Chūnagon." With "Chūnagon," it is possible to carry out searches that specify complex combinations of different morphological information (lemma, part-of-speech, conjugation type, lexical strata, etc.). The search results also display information on the source (magazine title, article title, year of publishing), author (name, sex, year of birth), data type (core, non-core), text type (conversation, quotation, other), text style (literary, colloquial, mixture, verse), etc. The author information includes a link to catalogues in the National Diet Library. By making use of this convenient service, it is possible to check how to read the name of the author of the article in question, to check when he or she was born and died, and, at the same time, to see if he or she made use of multiple other names. The "Chūnagon" search results also provide links that allow the viewing of images of corresponding pages in the original magazines.

Cast Your Net Wide: Finding Historical References in Parliamentary Data

Introduction

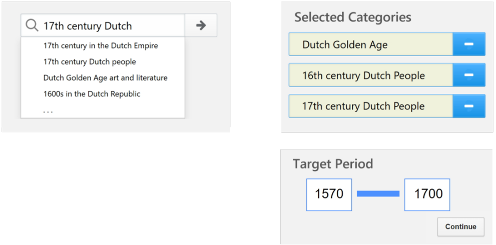
Analyzing how the past is molded to fit contemporary needs and priorities represents an intensely researched topic among historians, who have scrutinized (among others) the performance of "commemorative practices," the transmission of "collective memories," or, in general, "the language of the past." However, scholars currently lack adequate digital tools to assist them in this endeavor (Likaka, 2009; Piersma and Ribbens, 2013; Wilson, 2016).

The information needs of historians and other humanities scholars are not always adequately captured by traditional full-text search because query terms often serve as a proxy for more abstract concepts, while both items (the word and the concept) sometimes hardly overlap. This technology demonstration focuses on a specific type of concept, namely historical eras or periods.

Because of their complex and heterogeneous character, historical periods are difficult to capture with simple keywords. For example, the historian looking for references to the Renaissance in diachronic corpora will often encounter documents in which the term appears in its metaphorical sense, e.g. "the renaissance of train travel," instead of referring to the historical period. Besides yielding many irrelevant hits, keyword search also tends to overlook many relevant documents, because it ignores entities that are related to the query at a *conceptual* level, such as the painter Titian or the Nonsuch Palace.

Traditional full-text retrieval methods will obtain low recall and precision, when the target of a search comprises complex phenomena such as historical events or periods. To overcome these shortcomings, we introduce "WideNet," a tool that allows historians and other scholars within the humanities to search for information about specific periods in a multilingual corpus containing the Parliamentary debates from the United Kingdom, Canada, and the Netherlands.

WideNet models historical periods as a container of (hierarchically) related entities. The art historian, interested in how British MPs refer to the Italian Renaissance will, instead of retrieving all occurrences of the term “Renaissance,” be provided with speeches that mention, e.g., composers such as Costanzo Porta, and famous paintings such as The Bacchanal of the Andrians. Whereas earlier work proposed to use such entities as search suggestions (Piersma et al., 2014), we rather prefer a “sculptor’s approach” in which many containers of potentially relevant entities are initially included in the query, and may be deselected based on their empirical relevance.



17th century Dutch
17th century in the Dutch Empire
17th century Dutch people
Dutch Golden Age art and literature

. . .

Selected Categories
Dutch Golden Age
16th century Dutch People
17th century Dutch People

Target Period
1570 1700

Figure 1: Initial query specification in WideNet

These categories of entities are provided by a knowledge base (KB) that is loaded into the tool in advance. Our demo tool makes use of DBpedia, but any KB that conforms to the SKOS ontology may be loaded. The scholar, using WideNet, starts by selecting one or several root categories from a type-ahead search box (see Figure 1), and can further demarcate the query by selecting a time period, which will be used to prune the underlying entities of the selected categories. WideNet subsequently retrieves the network of narrower categories for each selected root category, and collects the contained entities as potentially relevant query components.

Figure 2: Assessing the relevance of categories and entities

The next step for the WideNet user is to assess which of the retrieved subcategories actually contain entities that lead to relevant results. The interface facilitates this task by showing, per subcategory, which entities are mentioned in the corpus, and how frequently, as well as which entities did not occur (see Figure 2). It also displays a list of preview results, showing limited context, to offer quick clues about the relevance of the category. This preview is also useful to identify individual entities that are not relevant after all, which can be deselected.

After inspecting and selecting relevant categories of entities, the demo interface allows further exploration by providing an environment in which the retrieved documents can be tagged and subjected to close reading. Moreover, the user can examine the results in relation to the parliamentary metadata, i.e. look for saliency by plotting the annotations over time, or study bias by comparing how often different political parties refer to the entities of interest.

WideNet offers a flexible and widely deployable interface that enables scholars to simultaneously search for myriad aspects that have shaped specific historical eras. It provides researchers with a holistic picture of how these periods are discussed in parliament, and thereby helps future scholars to get a more profound understanding of how history ties in with contemporary issues, and how societies deal with their past.

Textograf: A Web Application for Manuscript Digitization

Boris Orekhov
nevmenandr@gmail.com
National Research University
Higher School of Economics, Russia

Fekla Tolstoy
6975991@gmail.com
The Leo Tolstoy State Museum, Russia

Textograf is a web-based app for the digitization of manuscripts. *Textograf* is intended to automate the work of the textual critic of any handwritten text. *Textograf* allows you to select a specific set (or “layer”) of edits to a text, to compare different iterations of the text, and ultimately to visualize the correlation between the final text and the process that stood behind it. *Textograf* is able to work with prose and poetry, with manuscripts and printed sources. A description of the project can be found on the *Textograf* web page.

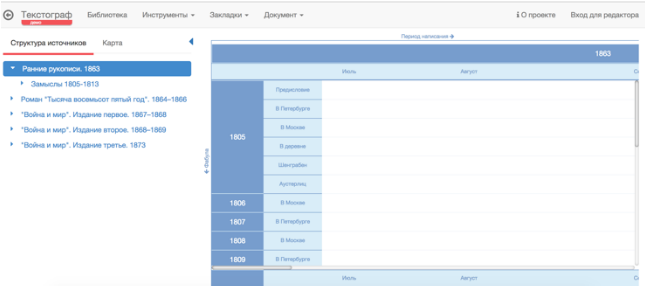
The app allows you to upload an image of the manuscript, to enter the transcript of the manuscript, and to match specific parts of the transcript with where they appear on the page of the manuscript. You can also mark on the transcript the different stages of edits that were made. The app also enables you to see and highlight all text that was deleted, all text that was added, and all text that was initially deleted and subsequently restored.

All documents (scanned images and texts) are stored in a so-called “library”. Access to the documents depends on the documents’ status – “public” or “private”. Private documents are visible only to the editor, public documents can be accessed by everyone.

Textograf allows its user to create complex documents that include manuscript images and their text versions. Text fields are searchable, allowing the user to find search results in the manuscript itself. Every manuscript image can be archived according to customized categories (whose handwriting, where it is currently stored, size of paper, pen or pencil, published or not published, etc).

Textograf allows you to download documents from the library in TEI format. Texts can then be ordered in accordance with the user’s version of the text. Often the text has a number of different versions, and the user has to find the right one and to collect all the corresponding manuscripts. *Textograf* makes this possible.

Different types of source documents connected to the work (outlines, synopses, the manuscripts themselves, printed editions) can be shown as an infographic, demonstrating visually the correlation between the different source documents. For example, this is a map of the early stages of Leo Tolstoy’s work on *War and Peace* displayed on the Textograf site.



The app was initially developed using the manuscripts of Leo Tolstoy: 200 pages (out of 5,000) from *War and Peace*.

The map has two axes: the real time of Tolstoy’s work (starting from 1863) and the fictional place and contents of the novel so you can see which episodes Tolstoy started with and how each part of the text came together.

As of today, the *Textograf* app is unique. It allows the user to work with manuscripts and texts in automatic or semi-automatic mode, meaning that the user can focus on the creative aspects of this work and become immersed in the manuscripts. Before the creation of *Textograf*, many of these functions had to be performed manually, such as establishing the link between text and image, and identifying the sequence of writing.

In the process of developing the application, we had to convert the terms and methods of textual criticism in terms of electronic resources. For example, we had to establish the meaning of the word "layer", or "edit", and to show how to visualize it on the screen.

When we talk about the influence different inputs, we mean that any text has a complex history. For example, a poem may obtain its final form as a result of a long history of changes from one version to another. Thus, what stays in the archives will be several manuscripts that contain similar, but not identical versions of the same text. Earlier versions will influence the later ones. The "text map" shows the full history and evolution of the text.

Textograf is designed to work with any paper-based sources. It could be both manuscripts and printed editions. *Textograf* is a computer programme editor and is designed to prepare in electronic form both critical and diplomatic editions.

Textograf can work with the manuscripts of any writers, be it Leo Tolstoy, William Faulkner, Oscar Wilde, Marcel Proust or anyone else.

As already mentioned, *Textograf* is a web-based application and cannot be installed on a computer. Integration with other tools is possible only through the files that can be downloaded from the application.

A Handbook of Electronic Literature Reading

Élika Ortega
e.ortegaguzman@northeastern.edu
Northeastern University, United States of America

Erik Radio
radio@email.arizona.edu
University of Arizona, United States of America

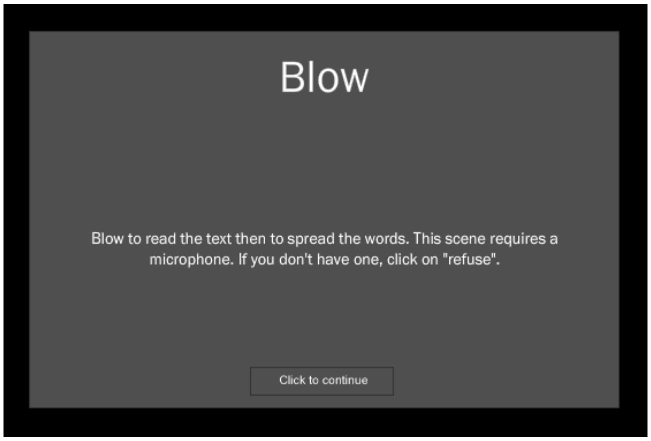
The changes effected by digital platforms on reading continue to be a contested area in popular culture, pedagogy, and higher education. This is also an area where electronic literature (e-lit), digital humanities scholarship, and information science can shed much light. Works of e-lit are a rich testing ground to explore how creative, non-commercial uses of digital media have been exploited and proposed to readers. In our *Handbook of Electronic Literature Reading*, we explore the reading instructions accompanying e-lit works to investigate the performative engagement of reading from the perspective of storage medium, objects and modes of interaction, and gestures or actions. The data included in the reading instructions shed light on how reading practices have morphed depending on platform historically over the last three decades. This focus has warranted an examination into current bibliographic practices to determine how the new modalities of e-lit require different descriptive methods and approaches to metadata creation.

Background

To say that digital reading platforms (web, e-readers, smartphones, etc.) are changing the way reading has been practiced in the age of print is now a truism. Often, these shifts have been the object of elegiac meditations (Birkerts, Manguel) and pedagogical concerns (NEA's "Reading at Risk" and "To Read or Not to Read"). These approaches highlight the 'erosion' that the practice of reading is undergoing. A useful corrective has been Andrew Piper's Book Was There. His call to think about reading from the basis of "the relationship between reading and hands, [and] the long history of how touch has shaped reading and, by extension, our sense of ourselves while we read" (3) has brought to light the bodily handling of reading objects. Our understanding of reading and text as a performative kind of practice has begun to take shape. For Rita Raley, text is "the whole of the event, its physical, logical, and conceptual architecture; the enactment and experience; its temporal structures; and associated social and juridical protocols" (2013: 21). Similarly, for Johanna Drucker, we need to elaborate "a different conception of artifacts (books, documents, works of textual or graphic art), one in which reception is production and therefore all materiality is subject to performative engagement within varied, and specific, conditions of encounter" (2014).

Electronic Literature Instructions

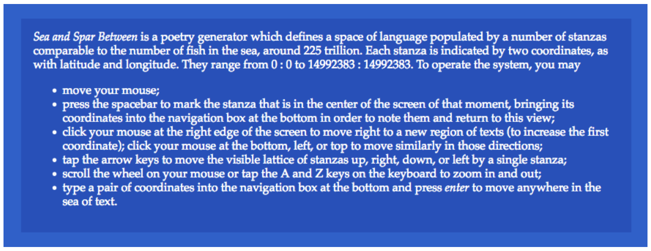
Though a sizeable body of e-lit scholarship has focused on matters like textuality, software, meaning making systems, code, preservation, etc. reading has not been at the forefront. The experimental qualities of e-lit have produced a great diversity of interaction modalities and ways of handling the objects that supports said experimentation. Nevertheless, an understudied convention of e-lit are the instructions accompanying most works. These instructions go from some of the most radically sensuous like Serge Bouchardon's *Blow*, "Blow to read the text then to spread the words. This scene requires a microphone" (Fig 1); to more conventional ones like "click your mouse at the right edge of the screen to move right to a new region of texts [and] tap the arrow keys to move" from Nick Montfort and Stephanie Strickland's *Sea and Spar Between* (Fig 2).



Blow

Blow to read the text then to spread the words. This scene requires a microphone. If you don't have one, click on "refuse".

Fig 1. Screenshot from Serge Bouchardon's Blow



Sea and Spar Between is a poetry generator which defines a space of language populated by a number of stanzas comparable to the number of fish in the sea, around 225 trillion. Each stanza is indicated by two coordinates, as with latitude and longitude. They range from 0 : 0 to 14992383 : 14992383. To operate the system, you may

- move your mouse;
- press the spacebar to mark the stanza that is in the center of the screen of that moment, bringing its coordinates into the navigation box at the bottom in order to note them and return to this view;
- click your mouse at the right edge of the screen to move right to a new region of texts (to increase the first coordinate); click your mouse at the bottom, left, or top to move similarly in those directions;
- tap the arrow keys to move the visible lattice of stanzas up, right, down, or left by a single stanza;
- scroll the wheel on your mouse or tap the A and Z keys on the keyboard to zoom in and out;
- type a pair of coordinates into the navigation box at the bottom and press *enter* to move anywhere in the sea of text.

Fig 2. Screenshot from Nick Montfort and Stephanie Strickland's Sea and Spar Between

The paratextual dimension of these instructions has been on the margins of the studies focusing on particular works. Cumulatively, however, the information kept on these reading instructions can signal the shifts that e-lit has enacted on reading in digital platforms. Even more broadly, as a sample of the many experimental and still unstable standards of reading in digital platforms, e-lit reading instructions can offer evidence of practices that may be becoming more integral to the act of reading. Similarly, the mentions of the hardware (mouse, microphone, keyboard, etc.) required to read e-lit works provide detailed insights on the historical role that technological developments have enacted on reading as a performative engagement.

Metadata and Description

The new affordances offered by e-lit increase the scope of bibliographic practices in ways that allow for more coordinated retrieval but also create greater depth and specificity in records as datasets. Many descriptive metadata standards have been largely shaped by the predominance of print media, and while its qualities overlap with those of e-lit, emerging characteristics of the latter require extensible structures to be considered comprehensively described. E-lit specific metadata sets have been developed by initiatives like Electronic Literature as a Model of Creativity and Innovation in Practice (ELMCIP) and the Electronic Literature Directory (ELD). However, among them there is still a variety of descriptive approaches and objectives. The Consortium on Electronic Literature (CELL) has taken significant steps towards interoperability and a "consensual model for the object of this field" (Baldwin) while still acknowledging the particular interest of individual archives and datasets. Efforts like this may still be enhanced through greater reconciliation with existing bibliographic procedures.

In e-lit the interaction between a work and a reader poses new ontological considerations for descriptive orientations suitable to examine the particularities of reading in digital platforms. Hayles' concept of intermediation proposes that the emergent processes that occur when reading e-lit forms a dynamic heterarchy in which both reader and work continuously inform and shape the trajectory by which reading unfolds (2007:100). This process reframes the ontic nature of work and reader, dissolving the duality into a single event. New qualities surface as a result, highlighting the different modalities through which intermediation occurs and inform bibliographic projects. Navigating these qualities and the language with which they are described poses new challenges for interoperability with similar collections in addition to being synthesized into the extensive legacies of bibliographic practices.

The Handbook

A Handbook of E-Lit Reading collects screenshots of the reading instructions of e-lit works and documents them according to storage medium (web, iPad, CD-ROM, floppy disk, etc.), actions or gestures (blow, click, scroll, type, etc.) and hardware (web cam, keyboard, mouse, microphone, etc.). The pilot target corpus includes ~200 works from over twenty countries anthologized in the Electronic Literature Collections Vol. 1, 2, and 3. The data extracted from the instruction pages will be analyzed and cross-referenced in order to observe emerging patterns like most common practices, most resilient ones, the rise and fall of some of them, as well as the introduction of new technological developments in hardware or software that have marked important shifts in the creation and reading of e-lit. This corpus, though not exhaustive, provides a starting point to design a suitable metadata set and test the categories included in it. Ultimately, the corpus will also encompass enough data to start drawing a hypothesis and identify future directions for the project.

Death by Numbers: Bills of Mortality in Early Modern London

Jessica Otis
jotis@andrew.*cmu*.edu
Carnegie Mellon University

The foundation of *Death by Numbers: Bills of Mortality in Early Modern London* is the construction of a relational database containing plague mortality information from the London Bills of Mortality in all their varying levels of granularity. Plague first entered England in 1348, as part of a continent-wide epidemic that killed approximately one third of the population of Europe. Thereafter, England suffered continuous outbreaks of plague through 1679, and fear of plague lasted well into the eighteenth century. The most well-documented epidemics of the early modern era were in England's cities, particularly London, which suffered six major epidemics in the century between 1563 and 1665, and lost an estimated 225,000 people to plague. During the mid-sixteenth century, in response to these epidemics, some city officials began to compile numerical summaries of local deaths and circulated those mortality statistics in manuscript form. By the turn of the seventeenth century, there was enough popular interest in these numbers that officials in the city of London began publishing weekly mortality statistics in a series known as the Bills of Mortality. The weekly bills included a parish-by-parish list of total deaths and plague deaths, along with running tallies of city-wide christenings, deaths broken down by a variety of causes, and parishes infected with plague. London's weekly bills were also supplemented annually with a general account of the preceding year, published on the Thursday before Christmas. Over the first half of the seventeenth century, more parishes were added to the bills, including the parishes in surrounding counties and in the neighboring city of Westminster, until the "Bills of Mortality" formed a recognized geographical unit that included all of London and its suburbs.

The Bills of Mortality are thus a vital source of information about the population of seventeenth- and eighteenth-century London. They have been analyzed by politicians, demographers, historians, and epidemiologists as early as the seventeenth century itself, but currently only the bills from a few select epidemic years are available online. Construction of the Bills of Mortality database is thus a vital step for both this project and for future digital humanists interested in the bills. After the construction of this database, this project will use network analysis to examine the transmission of plague between residents of London's parishes during both famous epidemic outbreaks and the periods of endemic plague that followed them. Subjects of particular interest in this analysis include the change in infection patterns over time, how the infrastructural and geographical features of the city act as barriers or "highways" to infection, and the devastating impact of – and slow recovery from – the Great Fire of London while plague was still active in the city. The project will also include a mapping component to visualize mortality trends by parish over time, with particular interest in the full duration of epidemics as opposed to each epidemic's highest mortality (and highest profile) year. Eventually the Bills of Mortality database, as well as materials associated with the network analysis and visualizations, will be made freely available online in accessible, sustainable formats for reuse by other members of the scholarly community.

Bretez II : La machine à remonter le temps

Mylène Pardoen
mylene.pardoen@wanadoo.fr
Institut des Sciences de l'Homme de Lyon, CNRS, France

Le poster met en lumière les collaborations nécessaires pour l'élaboration d'un projet transdisciplinaire complexe portant sur l'élaboration d'une maquette de restitution urbaine en 5D (comprenant, en plus du tridimensionnel, le déplacement et le sensible – ici le sonore) au contenu scientifiquement valide. Il en présente les articulations et les différentes phases de restitution ainsi que les productions possibles suivant les types de supports.

Bretez II est un projet restitution visuelle et sonore de Paris au XVIIIe siècle. Ce projet fait suite à *Bretez*, avec des équipes renouvelées afin de prendre en compte les évolutions et les nouvelles problématiques apparues en cours d'élaboration de la phase initiale. Ce programme de recherche propose un nouvel outil pour des applications en médiation scientifique et culturelle. Entrant dans le cadre des **humanités numériques**, *Bretez II* est projet transdisciplinaire fort de multiples interactions entre SHS (Sciences Humaines et Sociales) et sciences et technologies de l'information et de la communication (STIC – Sciences de l'Ingénieur), qui tous participent à l'élaboration de la maquette virtuelle.

Placé sous le parrainage de Daniel Roche (Professeur Honoraire au Collège de France – Paris), labellisé IMU (Intelligence des Mondes Urbains – LabEx de la région Rhône-Alpes – France), accompagné par la SATT (société d'accélération de transfert technologiques) PULSALYS (organisme de valorisation sur le bassin lyonnais), *Bretez II* est riche de ses nombreux partenariats. Outre les partenaires issus de la Recherche, nous pouvons également citer : le Musée Carnavalet (Paris-France), les Archives Nationales (Paris-France), pour les organisations institutionnelles, Labo-M, société franco-berlinoise de production de produits transmédia innovants et la start-up ASPIC (Tourcoing – France).

La zone restituée est un quartier de Paris aujourd'hui totalement disparu – 25 hectares situés entre l'apport de Paris, le Pont au Change, la rue de la Pelleterie et le quai de Gesvres, soit près la Place du Châtelet actuelle.

Ce projet se dénote par une **nouvelle approche** de la restitution du passé en **5D** (la combinaison du visuel [la 3D habituelle], le déplacement à la première personne [FPS] et la dimension sonore – le tout permettant une immersion, donc un meilleur ressenti) en s'appuyant sur une trame sonore de type hétérographique. La dimension **sonore**, cœur du projet, permet de rendre le passé disponible et tangible pour un très large public – complétant une vision méconne et scientifiquement valide de Paris. Il prend appuie sur une plateforme de jeu (Unity 3D et un middleware (Wwise).

Sa finalité est d'élaborer un **nouveau modèle** de restitution historique à destination large, dont la muséographie et la recherche : une matrice qui permette de se soustraire à l'obsolescence des supports et de permettre une diffusion sans renouvellement d'installations souvent coûteuses l'investissement. Initialement à destination des musées et des sites patrimoniaux, Bretez cible d'autres applications : **produits ludo-éducatifs** ou culturels sur supports nomades ou non, livres numériques, réalité virtuelle et augmentée, *in situ* ou non.

Ses spécificités :

- Une approche originale ;
- Le sensible comme vecteur complémentaire de recontextualisation ;

- Une dimension sonore cohérente avec l'histoire sociale et urbaine du quartier et la géométrie des architectures modélisées rendant sa prise en compte prééminente.

Les innovations du concept :

- La 5D : la 3D, le déplacement à la première personne [FSP] et la prise en compte de la dimension sensible – le sonore ;
- La modélisation volumique riche en détails – tant pour les intérieurs que pour les extérieurs des bâtiments – et leur génération en temps réels.

Les innovations concernant l'édition scientifique :

- Des nouveaux procédés éditoriaux de type hétérographiques ;
- Création d'un nouveau média impliquant la réalité augmentée.

Genealogies of VR in the archives

Elizabeth Parke
elizabeth.parke@mail.utoronto.ca.
University of Toronto, Canada

Liz Ridolfo
liz.ridolfo@utoronto.ca
University of Toronto, Canada

Using stereoscope cards and a stereoscope viewer from 1900, held in the Thomas Fisher Rare Book Library and the University of Toronto Mississauga Library, this poster presents the history of early immersive viewing experiences by tracing the history of 3D ways of seeing from the stereoscope cards to Oculus Rift and Google cardboard. Secondly, we offer tools for teaching with archival photographic materials, examining the histories of seeing, and integrating digital tools in the curriculum to enrich students' access to these cards' histories while also introducing recent VR development tools such as Unity, and Cardboard. Lastly, by using 3D scanning and printing we replicate the viewer, further expanding possible student engagement with DH tools, methods, and theories. The resulting student projects can be archived in a virtual exhibit (using Omeka), and the meta-data and data from the cards and viewer added to the objects' records.

The goal of this pilot project is to develop an 'out of the box' teaching resource for use in the classroom that offers analogue and digital engagement with rare materials, questions the histories of seeing stereoscopically, and contextualizes contemporary devises for seeing this way in a longer history of photography and immersive media that is often overlooked. Our project pushes students and researchers to consider the longer genealogy of virtual reality viewers and draws on previous work such as that of the Stereogranimator at the New York Public Library lab. In so doing, we seek to recover early histories of immersive media, photography, printing, and popular entertainment in the early 20th century.

Understanding Narrative: Computational Approaches to Detecting Narrative Frames

Eva Portelance
eva.portelance@mail.mcgill.ca
McGill University, Canada

Andrew Piper
andrew.piper@mcgill.ca
McGill University, Canada

Understanding narrative structure at a large scale remains a challenging problem within the field of cultural analytics and computational linguistics. Our aim with this project is to develop novel methods to study the pacing of narrative scene changes and the overall distribution of different plotlines within novels. Being able to analyze such narrative features at large scale can give us insights into the way different genres, time periods, or cultures favor different modes of storytelling. In this project we formalize definitions of narrative scenes and implement new methods of detection and clustering using computational methods.

The project involves three steps: creating an operational concept of a narrative frame; the algorithmic segmentation of narratives by frames; and the predictive clustering of frames into larger-scale "plotlines."

We define a "frame" as a significant shift of three variables in a given text window: entities, actions, and objects, which we represent using POS tagging as proper names, verbs, and nouns. We measure significant lexical shift of our three primary variables in a sliding textual window of 1000 words with increments of 100-word shifts. We test window-size and variable selection relative to human annotation to determine the best performing model. We resolve frames into "plotlines" using hierarchical clustering, also demonstrated in our poster. "Frames" serve as inferred textual units and "plotlines" as aggregated clusters of frames.

We have tested the performance of different combination of variable selection on nine 12,000-word passages from novels of different genres from a range of time periods (from 1818 to 2011). To date, our algorithm outperforms the current state-of-the-art in Hearst's Texttiling algorithm

(1994; 1997) when it comes to placing breaks in the narrative event progression. The performance of our system relative to human performance on the same task (F1 82%, Precision 81%, Recall 86%), shows an F1 score of 69% with 71% precision and 67% recall, where ⅔ annotators agreement is considered to be a true frame boundary. Hearst's method applied to the same problem performs at a significantly lower rate (F1 18%, Precision 18%, Recall 19%). While the overall problem remains challenging we show significant improvement over state of the art systems at detecting narrative segments. Nevertheless, the imperfect accuracy suggests that scene changes have a number of subtle variables that are not exclusively tied to vocabulary or character shifts, which indicate further avenues for future research.

Our poster will present our formalization of narrative events, the results and approach of the segmentation task and the clustering models used. We see this project as a crucial contribution to the larger study of narrative form across different literary genres and time periods.

University of Toronto, Canada

VisColl is a data model and associated tools that are designed to help scholars to visualize the physical collation of medieval manuscripts. In manuscript descriptions and library catalogs, a collation is normally given in the form of a formula, which describes each quire in terms of the position of that quire in the manuscript, how many leaves the quire contains, and if any leaves have been added or removed. A diagram may also be used to illustrate the same information, with the added benefit of clearly showing which leaves are conjoined (conjoined leaves are also known as bifolia). VisColl enables scholars to model the collation of manuscripts and then to present that information in various ways, including diagrams and formulas, but also in novel ways distinct from collating a manuscript by hand. For instance, in addition to visualizing the physical structure of a manuscript, the Beta Version of the VisColl data model currently under development enables users to create taxonomies describing the content of the manuscript, and other elements, which will enable tools to link those taxonomies to the physical structure, producing a more robust and descriptive visualization than is possible in the current system.

VisColl was conceived in the mid-2000s by Dot Porter during her work at the Collaboratory for Research in Computing for Humanities at the University of Kentucky (UKY). Porter developed the tool in order to address issues she encountered in effectively visualizing standard descriptions of manuscripts in scholarly works. For instance, in *Beowulf and the Beowulf Manuscript* Kevin Kiernan uses the physical construction of the manuscript to make arguments about the dating of the text (separate from the dating of the manuscript itself). In addition, Ben Withers (of UKY), in *The Illustrated Old English Hexateuch, Cotton MS. Claudius B.IV: the Frontier of Seeing and Reading in Anglo-Saxon England*, similarly used a detailed collation statement of the manuscript as the backbone for his investigation of the construction of the manuscript. There are numerous examples of scholarly works that build an argument about the dating and construction of manuscripts based on the collation of the physical object. In consulting such works, Porter saw an opportunity to enable readers to better visualize the structure of the object beyond the limitations of traditional formulas, diagrams, and collation statements.

Digitized medieval manuscripts are typically viewed through page-turning interfaces, which give the impression of page openings, but lack the physical cues present in a physical book, i.e., the size of the book, its thickness, details of the parchment or paper, etc. Indeed, page-turning interfaces do not usually show a picture of book openings at all, but rather they are composites made with two images: one of the left-side page and another of the right-side page. These images would have been taken at different times. Typically all images of one side pages are taken first, e.g. all the rectos, then of the other side, and then file names or structural metadata are used to order the files correctly in post processing. Most digital libraries provide some information on the pages depicted, and views other than single pages: all provide information on the folio number and the side (recto or verso) shown; some indicate the quire number, and some offer a variety of viewing modes, such as single pages, double pages, pages of thumbnails or thumbnails presented filmstrip-style across the bottom of a page. However, again, for the most part, the focus of these resources is on the page, rather than on the physical object. Even the Turning the Pages™ software, conceived by the British Library in 1996 (and developed by Amarillo Systems since 2001), which, since version 2.0 (2006), has produced realistic three-dimensional books (including the ability to mimic the different movement of paper and parchment pages as these are turned), lacks any modelling of the gathering structure. To present knowledge, there is no institutional digital library that describes the physicality of manuscripts outside of the standard Physical Description section of the manuscript records and collation formulas.

The Alpha Version of the VisColl data model is implemented in the Collation Modeler and the Collation Visualizer hosted at the University of Pennsylvania, but the data model was envisioned as agnostic and was designed to be easily used by other collation tools. The University of Toronto, through a Mellon-funded project entitled Digital Tools for Manuscript Study, is developing a robust VisColl web application which implements the Beta Version of the data model, and allows users to visually manipulate and present diagrams and metadata in real time, while also making use of the International Image Interoperability Framework (IIIF) to integrate digital manuscript images alongside scholarly work.

This poster will document the stages of the development of VisColl, from its conception to its current instantiation, highlighting the steps taken and the reasoning behind each new actualization of the project, and will also serve as a demonstration of the current version of the tool developed by the University of Toronto Libraries. Documentation and code of this version can be found and downloaded from the University of Toronto Libraries' GitHub page. The current state of development can be found at VisColl's GitHub page, which documents each new build, and from which the project's code can be downloaded.

The London Brewers' Prosopography: Parsing Historical Apprenticeship Records

Harvey Quamen
hquamen@ualberta.ca
University of Alberta, Canada

This poster describes one preliminary aspect of a new project about the history of beer and brewing in London. I am building a prosopography of brewers' apprentices in the years from about 1530 to approximately 1800. A catalogue of apprentices and their masters can teach us not only about the social and cultural history of British beer during that time but about the social network of people working in the industry. During this 270-year period, the Worshipful Company of Brewers, the medieval brewing guild first established by Henry VI in 1438, logged nearly 10,000 apprenticeship records (Webb), a collection that serves as just one of many potential datasets that can yield insights into England's brewing culture.

The more immediate goal described in this poster, then, is how to parse these 10,000 records into component parts— people, places, occupations, and dates—so that these relationships can be analyzed and mapped over time. A typical apprenticeship record looks something like this:

AMBROSE John s John, Ilsley, Brk, maltster to Samuel May 14 Jul 1703

In other words: John Ambrose, whose father is John Ambrose from Ilsley, Berkshire and is a maltster by profession, was apprenticed to Samuel May and the fee was paid on 14 July 1703. The record lists three people, a parish, a county, a profession, and a date—a typical dataset found when tracking apprenticeships (Lane).

The simplicity and regularity of that template tantalizingly suggests writing an automated parser, which I am doing with an open source Python module called *pyparsing*. Although these recursive descent parsers, as they are called, are designed for more elaborate projects (like writing compilers), they are the perfect tool for a job like this because they allow users to construct grammatical "rules" that look like simple additions. For example, the record above can be parsed according a grammatical rule that looks like simple Python:

```
apprentice + father + location + occupation + to + master + date
```

But the wide variety of apprenticeship records presents a challenge. As it turns out, the first 10% of the apprenticeship records require nearly 40 different template “grammars.” The effectiveness of an automated parsing approach—useful but nonetheless somewhat limited—is the main point of the poster. Supplementary strategies (like natural entity parsing and dictionary lookups) may provide some help and, if they prove themselves worthy, they will become part of the presentation as well.

The Use of Cognitive Digital Games in School: Contributions to Attention

Daniela Karine Ramos
dadaniela@gmail.com
Universidade Federal de Santa Catarina, Brazil

Bruna Anastacio
brunaanastacio@hotmail.com
Universidade Federal de Santa Catarina, Brazil

Cognitive games involve a number of different games working aspects of human cognition, while proposing the intersection between the sets of concepts, fun and cognition, for the improvement of cognitive functions. The attention is the main point made in this study, since it is fundamental to the learning process and be recurring complaint among parents and teachers in schools.

With respect to the contributions of digital games to improvement of cognitive processes, researchers suggest that regular practice has a significant influence on improving the performance related to basic visual skills (Li, Polat, Scalzo, & Bavelier, 2010); on the ability to perceive objects simultaneously (Dye & Bavelier, 2010; Feng, Spence, & Pratt, 2007); and on the ability to do more than one task at the same time (Boot, Kramer, Simons, Fabiani, & Gratton, 2008). Other studies specifically investigate the use of digital games in the school context and suggest potential for digital game use to improve of student's attention span at preschool age (Rueda, Checa, & Cómbita, 2012), to improve overall intelligence capacity of elementary school children (Miller & Robertson, 2010), and to better performance of working memory ability (Klingberg et al., 2005; Thorell, Lindqvist, Nutley, Bohlin, & Klingberg, 2009).

Considering the importance of the proper functioning of attention, because of its involvement in the regulation of thoughts and emotions, maintaining the performance of this process is very important, especially in school, where the child must acquire content in an environment full of countless distractors. The study in question focuses on the attention, proposing and evaluation in the context of the classroom. Thus, it suggests the use of digital games in an integrated way the school activities in the classroom.

The games have features like increasing challenges, rules that establish what can and cannot be done, and involvement of the player in the quest to gain skills and win the game (Kirriemuir & McFarlane, 2004; Prensky, 2006).

We aim to investigate the contributions of the use of a system that integrates cognitive digital games to a database, of the Escola do Cérebro, for monitoring and improvement of cognitive skills, highlighting the attention. The games involve challenges and rules involving the exercise of cognitive functions, especially the working memory, attention and capacity of solving problems.

The study combines qualitative and quantitative approaches. It collects the data based on the observation of the proposed interventions as well as interviews conducted with participating teachers and students to identify their perceptions of digital games’ contributions to the learning process. Furthermore, before and after the implementation of the intervention, we performed a D2 Test of attention that measures selective and sustained attention, as well as visual scanning accuracy and speed.

The intervention consisted in the use of the Escola do Cérebro, using tablets in the classroom, daily for a period of five weeks. The sample consisted of 71 students of the Application School of Basic Education, Federal University of Santa Catarina, aged 7 and 9 years old ($M = 7.64 \pm 1.12$), which were divided into two groups: participant and control. The first ($n = 31$) participated in the intervention, the control group ($n = 40$) was only evaluated using the test before and after the same time interval of interventions.

The Escola do Cérebro is a platform that integrates seven digital games into a database. The application allows visualization of the player's performance and offers the possibility of monitoring by teachers. Students have their scores measured by four variables: time, speed, stability and accuracy.

A statistical analysis was performed based on the application of the paired t-test on the difference of the overall score obtained in the test before and after the intervention in the two groups. The difference in the results obtained from the application of D2 Test of attention before and after was statistically significant (p <0.05), the participant group had mean and standard deviation 60.23 (64.75) respectively, while the control group was 20.00 (42.65).

The result indicates significant improvement in the performance of the sustained attention in the test, as well as a high dispersion, which reveals a variation in relation to the performance.

In addition, students participating in the interview reported a preference for games that involve problem solving, recognize the need to plan actions in relation to their importance for the game and for daily activities, and realize improvements in the ability to sustain attention. The teachers observed changes after the intervention, emphasizing the greater persistence and involvement in school activities, and in some students, improvement in the ability to sustain attention. From this, we conclude that an intervention based on cognitive digital games offers contributions to the learning process and improvement of sustained attention.

Frequently Cited Passages Across Time: New Methods for Studying the Critical Reception of Texts

Jonathan Reeve
jonathan.reeve@columbia.edu
Columbia University, United States of America

Milan Terlunen
m.terlunen@columbia.edu
Columbia University, United States of America

Sierra Eckert
sierra.eckert@columbia.edu
Columbia University, United States of America

Text reuse detection technology and approximate text matching have made possible the large-scale computational identification of intertextuality. These technologies have often been used in plagiarism detection and in studies of journalistic text reuse. Fewer studies, however, have applied these methods to humanities research. We present a method for quantifying the critical reception history of a source text by analyzing the precise location, density and chronology of its citations.

Our work builds on a recent set of digital humanities projects that use text reuse detection in order to study the afterlife of texts through textual quotation. The Viral Texts project and Digital Breadcrumbs of Brothers Grimm take algorithmic approaches to studying text reuse and circulation in their respective fields of research: nineteenth-century popular press and folklore. In both projects, the focus is on using text reuse detection to uncover hidden networks of reuse—the reprinting of short news items and the reuse of motifs or minimal narrative units in folklore—in corpora without standardized conventions of citation. Our project seeks to take this work a step further, by applying a similar method in a different area of cultural production where more standardized citation con- ventions already exist: academic citations. We draw on the work of Dennis Tenen—in using extracted citations to critically visualize the “knowledge domain” of Comparative Literature—and a recent project by JSTOR Labs that uses the text of Shakespeare’s plays and the U.S. Constitution to visualize the scholarship surrounding passages in those sets of texts (Tenen, forthcoming in 2017). Like these projects, we hope to leverage the explicit and institutionalized nature of academic citation in studying text-reuse patterns, using text reuse to ask questions of critical attention in canon formation. By focusing initially on a single text in order to ask about its critical reception history, we hope to provide new methods for studying not only text-reuse patterns, but the sociology of citation practices—studying changes in when, how, and what critics cite from a given text.

In applying these methods to literary scholarship, we've chosen to start on a relatively small scale. George Eliot's novel Middlemarch is an ideal test case, due to its length, copyright status, stable editorial history and canonicity. Perhaps most appropriately for this study, Middlemarch is known for its narrator's wise generalizations—highly quotable fragments that have been featured in more than one Victorian volume of George Eliot's sayings. For the full project we are working with JSTOR Labs to assemble a corpus of all 6,500 articles on Middlemarch in their collection. The figures below display preliminary results with a smaller 483-sample corpus.

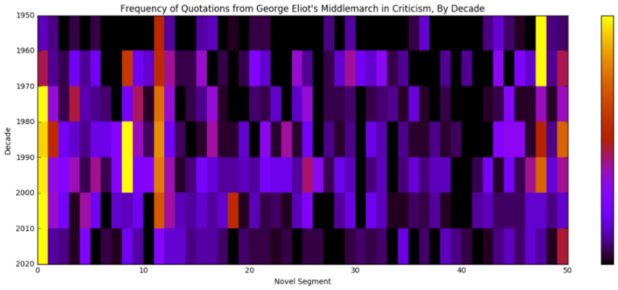

Figure 1. Citation Frequency Heat Map for Middlemarch, by Decade

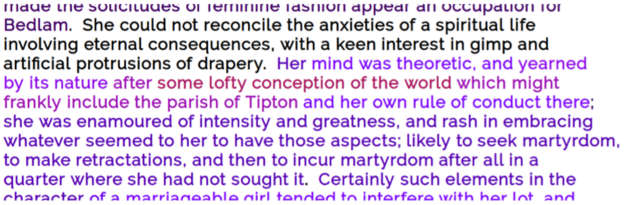
At the largest scale, Figure 1 shows the frequency of citations across the whole of Middlemarch as a heat map segmented by decade, with yellow signifying the highest citation and black, no citations. Here, the novel is broken into 50 segments along the horizontal axis, and each segment is colored according to the number of times any part of its text has appeared in the critical literature. A number of overall trends are noticeable here. The very beginning and the end of the novel show the most numbers of quotations, followed by the first quarter of the novel. Overall, the second half of the novel, except for the ending, is significantly less quoted from than the first half.

Viewed chronologically, we see that critical interest in certain sections—as expressed in numbers of quotations—appears to shift over time. In the 1950s, most of the critical citation was of the end of the novel, at its climactic third-to-last section, but this interest has faded almost completely by the present day. At the same time, critical interest in the beginning of the novel seemed to be at a relative low point in the 1950s, but quickly became a highly quoted segment by the 1970s. This shift may represent a change in critical attention to the parts of the novel, shifting from the end of the novel at midcentury to the beginning of the novel, where it still appears to rest.



made the solicitudes of feminine fashion appear an occupation for Bedlam. She could not reconcile the anxieties of a spiritual life involving eternal consequences, with a keen interest in gimp and artificial protrusions of drapery. Her mind was theoretic, and yearned by its nature after some lofty conception of the world which might frankly include the parish of Tipton and her own rule of conduct there; she was enamoured of intensity and greatness, and rash in embracing whatever seemed to her to have those aspects; likely to seek martyrdom, to make retractations, and then to incur martyrdom after all in a quarter where she had not sought it. Certainly such elements in the character of a marriageable girl tended to interfere with her lot, and

Figure 2. Citation Frequency Text Browser for Middlemarch

Figure 2 shows a finer grained analysis, no longer segmented by decade, displaying an excerpt from our paragraph-level text browser for Middlemarch. Here again, the color coding represents the number of quotations of each segment, ranging from unquoted black passages, to infrequently quoted purple and red passages and more frequently quoted yellow ones. In our sample, the somewhat abstract contrast between "spiritual life" versus "gimp" and "drapery" remains unquoted, whereas the short, punchy "Her mind was theoretic" has triggered numerous quotations, peaking with the stirring phrase "some lofty conception of the world", before the frequency falls again slightly as the narrator describes how this character's idealism clashes with the real world. This annotated edition could provide both scholars and students of literature with a way to read the novel for passages that have been most discussed in secondary literature, and for passages that have been critically neglected.

The potential applications of this methodology are numerous and wide-ranging. Firstly, this methodology can be used in any discipline to investigate the discipline's theoretical history. As with the 1980 study of Wundt's influence on the field of psychology (Brožek, 1980), our methodology could rapidly and easily produce similar investigations for the influence of Saussure in linguistics, Bourdieu in sociology, Mead in anthropology, Beauvoir in feminist theory, and so on. Moreover, this analysis would be much more fine-grained, registering not only the frequency of works cited but also specifc sections, passages and even key phrases within them.

In addition, we see particular relevance of our methodology to disciplines substantially engaged in questions of quotation and commentary. In theology, commentaries on sacred texts could be analysed in this way to give insights into the texts' interpretive history. In philosophy, the citation of key texts in later periods could be used to assess the shifting priorities of subsequent generations of philosophers. Legal scholars, given the exceptional value placed on precedent in law, have long been interested in using digital technologies and studying citation practices (both of which underpin the recent Ravel project at Stanford University's Law School), which our methodology would make even more granular (not just page numbers but exact phrases).

To return to literary studies, while our own initial project is focusing on academic literary criticism of the post-war period, the methodology could equally be applied to earlier aspects of literary reception. We are interested to examine whether patterns of citation change measurably since English literature is established as a discipline in the late nineteenth century. Going even further back, our methodology could equally be applied to quotations of literary works in non-academic formats, whether non-fiction (newspapers, journals, essays) or other literary works (citations of Shakespeare in Romantic poetry, say).

Our own next steps in this project will be to expand our corpus of quoted texts—the single texts whose citations we are tracing. Do similar patterns of citation apply to Eliot's other novels? Do they apply to novels by Dickens, or by Austen? These analyses will allow us to begin to formulate general hypotheses about patterns of quotation within literary scholarship of recent decades, while also offering unprecedented insights into the works of each of these authors.

The Tasso in Music Project: A Digital Edition of the Musical Settings of Torquato Tasso's Poetry, ca. 1570–1640

Emiliano Ricciardi
ericciardi@music.umass.edu
UMass Amherst, United States of America

The Tasso in Music Project, currently funded by an NEH Scholarly Editions Grant (2016-2019), is an open-access and interactive digital platform that allows music historians, performers, and literary scholars to access and analyze late 16th- and early 17th-century settings of poetry by Torquato Tasso, arguably the most prominent literary figure of early modern Italy. The project has been realized by a team of scholars from North America and Europe, with the technical support of Stanford University's Center for Computer Assisted Research in the Humanities (CCARH) and UMass Amherst. Upon its completion, the Tasso in Music Project aims to provide upon critical editions of the about 650 extant musical settings of Tasso's poetry, the vast majority of which have never been edited before. These settings represent the work of over 100 composers from a variety of geographic areas and with different musical styles, and as such provide a snapshot of secular vocal music in an age in which it underwent profound transformations. In addition, these settings shed light on Tasso's extraordinary influence on the music of his time– an aspect of his reception that has received surprisingly little attention to date.

The editions, which constitute one of the largest digital repositories of Italian madrigals and related genres, are encoded with Humdrum software tailored specifically for the project by Stanford's CCARH. The editions are presented on the project's website in a variety of electronic formats, such as MEI, MuseData, MusicXML, MIDI, and PDF, among others. They can also be visualized online using Verovio, a recently developed SVG viewer for music encodings. The editions are accompanied by dynamic, in-score critical notes and by music and textual search tools developed by Stanford's CCARH that facilitate analysis of this repertoire. Some of these search tools– such as single pitch and melodic or rhythmic pattern– draw on CCARH's work for the Josquin Research Project, a platform for the analysis of Renaissance music that has received wide recognition in the early music community. Other tools are unique to the project, including those that allow users to run combined musical/textual and vertical sonority searches that are crucial for the study of this particular repertoire.

The platform also features a substantial textual component, with TEI transcriptions of the poetic texts as they appear in the musical settings and in contemporaneous literary sources, both manuscript and printed. The textual apparatus allows for a dynamic visualization of literary variants, thus facilitating the collation of different sources. Thanks to this feature, the project will become an indispensable resource for literary scholars interested in the tradition and transmission of Tasso's poetry, as well as for music historians interested in tracking the literary sources from which composers may have drawn the texts they set to music.

The Tasso in Music Project addresses an interdisciplinary audience, bringing together two institutions invested in the development of digital platforms for musical and humanistic research as well as a group of scholars from the North America and Europe who form the project's editorial and advisory boards. As such, the project may serve as a model for institutional cooperation, opening avenues for interdisciplinary approaches to the creation of digital databases of music and poetry from the late Renaissance and early Baroque periods.

Photogrammar and the Federal Writer's Project: A Model for Teaching Data and Mapping Rhetoric

Courtney Rivard
crivard@email.unc.edu
University of North Carolina Chapel Hill
United States of America

Laura Wexler
laura.wexler@yale.edu
Yale University, United States of America

In a poster session "Photogrammar and the Federal Writer's Project: A Model for Teaching Data and Mapping Rhetoric," we outline the use of some of the educational opportunities we have discovered in using large Digital Humanities projects to create *collaborative partnership pedagogies* to teach students digital rhetoric. In this approach, students become project managers serving the needs of a real world research client – Yale University, the University of North Carolina, Chapel Hill and the University of Richmond's collaborative Photogrammar team.

Bringing together pedagogical theories in Composition and Rhetoric that stress the importance of understanding the role of rhetoric in the construction of digital texts (Sayers, Sample, Galloway) and strategies for equitable collaborative practices in Digital Humanities (Posner and Algee-Hewitt), we teach students to "critically make data" by becoming project leaders tasked with textual mark-up and metadata creation using digitized archival documents. As team leaders, students must think through key rhetorical issues involving naming practices, organizational practices, and user interface and access with a mind toward both historical authenticity and greater inclusion. In this way, they participate robustly in contemporary real world debates about civility, discourse, history and accountability in naming persons, events and things. Therefore, this pedagogical approach opens access into the center of current pedagogical and historical concerns.

The Photogrammar project brings together photographs by the Farm Security Administration taken during the Great Depression and World War II with life histories created through Federal Writers' Project. The new tools currently in development will offer users the opportunity to search and map both the visual and textual histories of the Great Depression in relation to each other. These life histories hold great historical significance as they mark an important precursor to the development of oral history methodology by collecting the histories of people who were previously excluded from the historical record, including women, the working class, and African Americans (Couch, Hirsch, Penkower). Since they will function in some sense as extended captions to the FSA/OWI photographs, adding the life histories also touches upon important issues in the history and criticism of visual culture. Additionally, they hold linguistic keys to racial, gender, class, sexuality and location classification patterns of the time that the photographs alone may not expose. Ethical as well as methodological issues in bringing buried histories to light vividly arise.

Applying collaborative partnership pedagogies in an undergraduate course in Composition, Rhetoric and Digital Literacy at the University of North Carolina that had no prerequisites, students were tasked to create a metadata schema for the life histories to be added to Photogrammar, using TEI to create rules for encoding the text. Because most students entered the class with little technological or collaborative skills, the course places students in small working groups and used Trello (project management software) to organize work flows for lower stake exercises designed to address larger theoretical issues in digital rhetoric (Eyman, Hart-Davidson, Ridolfo). These small stakes activities helped students develop the skills necessary to tackle the larger project that required them to work through critical issues of power stemming from the task of making archival material from the 1930's useful in a digital setting today. For instance, some of the language used to classify racial groups in the FSA and the Federal Workers Project is off-putting, or even offensive today. Students had to come to consensus on such difficult issues because the project required that they present (via skype) their rationale for the metadata schema to a Photogrammar Co-Director. The Co-Director then gave feedback, which students used to write their schema rationale within the TEI of the archival documents. Their decisions did an excellent job of balancing the need to maintain the historical authenticity of the documents while using technology in the service of great inclusion and social justice are now used as the template for the entire life histories collection. Therefore, they not only learned crucial transferable digital skills, but also were given the ability to contribute materially to how the historical record is produced.

Based on the students' work, it will be possible to map the movement of interviewers, trace the prevalence of important issues of the time such as sharecropping, women's labor, WPA work, and mill work, and generate comparative analyzes of rhetoric used via specific interviewer practices. This project highlights the new kinds of classroom as well as scholarly opportunities that arise when rhetorical questions and insights begin to allow students to direct and inflect the further development and build-out process of an established DH site.

Tropy: A Tool for Research Photo Management

Stephen Murray Robertson
srober30@gmu.edu
George Mason University, United States of America

Abigail Mullen
abby@lincolnmullen.com
George Mason University, United States of America

Tropy is a freely licensed and open-source software tool currently under development by the Roy Rosenzweig Center for History and New Media that will allow researchers to collect and organize the digital photographs they take in their research, associate metadata with those images, and export both photographs and metadata to other platforms.

Tropy is filling a critical need in the workflow of researchers who visit archives. This need for photo management has largely arisen since the widespread adoption of photographing sources in the archives instead of reading and analyzing them on-site. Postponing analysis to a later moment in the research cycle proves more difficult than most scholars anticipate: according to the ITHAKA S+R report "Supporting the Changing Research Practices of Historians" (2012), researchers now typically photograph everything they can, and then, faced with "the lack of tools or software to facilitate the process of capturing and using digital photographs for scholars," struggle to "organize and access photographs in a constructive way after a trip." Researchers typically depart from the archives with photographs that might include limited EXIF metadata about the image but never contain any metadata describing the imaged artifact itself. At present it is difficult if not impossible for researchers to attach such metadata to images, particularly regarding their provenance, and to organize them so that scholars can identify and find what is important to their research projects.

With Tropy, you will be able to:

Import. You will be able to drag and drop one or more JPG images into Tropy. Importing will add the image files to Tropy's internal data store, generate thumbnails for each of the new images, and add preliminary metadata based on a template.

Edit. Tropy provides the core functions needed to ensure that images are adequate for your purposes; it is not intended to be a full-featured image editing software. You will be able to rotate, crop, zoom, and adjust contrast. Each image's metadata will also be individually editable. Available fields will be supplied by customizable templates: Tropy will include generalized archive templates, based on Dublin Core and EADS; and researchers and archivists will be able to create their own templates, customized to reflect specific collections and archives. A batch-editing mode will allow users to manipulate metadata across multiple images. Tropy will also include an interface for note-taking and transcription.

Organize. Images will be organized via collections and/or tags, with items able to appear in multiple collections and under multiple tags. You will have many ways of finding your archival images: browsing image collections and tags via list and thumbnail modes; sorting these views using all available metadata, such as date, source archive, and title; and searching across all available metadata, including notes.

Share. All items stored in Tropy will be available for export both locally and to external, web-based services. Exporting a selection of items or a collection from Tropy will generate an archive file that includes image files along with their metadata in machine-readable format. You will also be able to transmit your images and metadata to external services via Tropy plugins. We will create at least three plugins spanning a range of services – Flickr, Omeka and an open-source digital asset management software (DAMS) – as well as documentation that allows users to develop their own plugins.

We anticipate a beta release of Tropy in April 2017, and a 1.0 release in September 2017.

Mnemosyne, Digital Library for Rare and Forgotten Texts (1868–1936): Collections and Digital Editions

Dolores Romero López
dromero@filol.ucm.es
Universidad Complutense de Madrid, Spain

Lucía Cotarelo Esteban
luzia_cotarelo@hotmail.com
Universidad Complutense de Madrid, Spain

José Luis Bueren Gómez-Acebo
Biblioteca Nacional de España, Spain
joseluis.bueren@bne.es

The objective of *Mnemosyne*, Digital Library for Rare and Forgotten Literary Texts (*1868-1936)* is to select, categorize, and make visible (in a digital format) literary texts that belong to a forgotten repertoire in order to allow the historiografical review of the period. *Mnemosyne* has a repertoire of texts and authors who have remained in the shadow of the great literary figures of the first third of the 20th century. This digital library intends to be a field of international experimentation for the creation of interoperable semantic networks through which a large group of scholars could generate innovative research and theoretical reading models for literary texts.

Mnemosyne aims to be an open-access digital library allowing data modelling for **specific collections** (such as intellectual women, Madrid in the Silver Age literature, children kiosk literature, science fiction, photonovels, etc.) in support of research and teaching on Silver Age Spain. Through *Mnemosyne* it can be accessed digital edition of texts. The digitization of these works has been carried out by public and private institutions. The first version of the library is stored on the server of the Universidad Complutense de Madrid Library, itself linked to the collections of the digital library HathiTrust.40 In a search conducted in *HathiTrust* in 2012, the names, surnames, and pseudonyms of selected authors were used to locate a total of 2,873 digitized texts corresponding to "odd and forgotten" writers. The *Biblioteca Digital Hispánica*, which serves as the access portal for the digital collections of the *Biblioteca Nacional de España*, provided 2,448 works by male authors and 1,017 works by female writers. Now we are working on the **interactive editions** of some short stories with the support of the Spanish Biblioteca Nacional.

Behind the scenes of Mnemosyne's public presence online, the project is developing with the aid of the tool *Clavy*. *Clavy* is an RIA (Rich Internet Application) that is able to import, preserve, and edit information from collections of digital objects so as to build bridges between digital repositories and create collections of enriched digital content. *Clavy* also provides a basic system of data visualization, edition, and navigation. There are plans to integrate *@Note*, a collaborative annotation application, into *Clavy*. These two computational tools were developed by the ILSA at the Universidad Complutense de Madrid.44 *Clavy* facilitates the import, export, and edition of records in multiple formats such as MARC2145, as well as their integration into Mnemosine's predesigned model with a view to their export into other compatible formats like XLS (Excel Binary File Format) or XML (Extensible Markup Language), or into other systems like OdA.46 Using *Clavy*, metadata for more than four thousand digitized objects from *HathiTrust* and the Biblioteca Digital Hispánica have already been imported into the *Mnemosyne* database. Logically, the data from these sources was described in MARC21, following the rules for library catalogs. The outcome was forseeable: in some cases, *Mnemosyne's* data model did not require the degree of detail furnished by MARC21, while in other cases it was necessary to incorporate new information absent from that format.

Acknowledgements

Mnemosyne, Digital Library for Rare and Forgotten Literary Texts (1868-1936) is the work of two research teams (LEETHI and LOEP) affiliated with the Universidad Complutense de Madrid and funded by the publicly subsidized national research project "Escritorios Electrónicos para las Literaturas" (Referencia FFI2012-34666, 2012-2015), by the private BBVA Foundation which subsidized the Project "Modelo Unificado de Gestión de Colecciones Digitales con Estructuras Reconfigurables: Aplicación a la Creación de Bibliotecas Digitales Especializadas para Investigación y Docencia" (2015-2017) and by eLITE-CM project "Edición Literaria Electrónica (Ref. S2015/HUM-3426, 2016-2018)".

Information and System Design for Diversity: Can We Do Better?

Amanda Rust
a.rust@northeastern.edu
Northeastern University, United States of America

Julia Flanders
j.flanders@northeastern.edu
Northeastern University, United States of America

Digital information practitioners across many areas seek to preserve and provide access to the voices of disenfranchised and marginalized communities. However, the curation of cultural objects often comes with colonial implications and power-based hierarchical differentials. Providing access to the collections of these groups requires genuine, responsive cooperation, and it also requires that the technical and information systems through which we engage community contributors and participants be equally responsive to diverse cultural circumstances and needs. With support from an IMLS National Forums grant, the Northeastern University Digital Scholarship Group seeks to facilitate a national conversation from which we can learn about responsible partnership in digital projects involving such community-driven collections. We will host a series of public and working meetings to produce a teaching and learning toolkit, to prompt education and change in the approach to systems design for diverse and culturally-sensitive materials.

The need for community-driven pedagogy in this area is well recognized. Practitioners in many fields seek genuine, responsive partnership with the communities in which cultural artifacts were created (See, for example, the repatriation policies of the United States' National Museum of the American Indian or Johnston on recent discussions of repatriation prompted by new publications in the museum field.), deeper understanding of the hegemonic role of knowledge representation via standardized ontological decisions (Berman 1971, Olson 2002.), and investigation into the role of algorithm, interface, and tool design in reinforcing power differentials inherent in the status quo (McPherson 2012, Sweeney 2013, Chun 2011) These topics also arise in venues such as journal special issues (see, for example: *Code4Lib Special Issue on Diversity in Library Technology,* 2015; *Archival Science Special Issue: Keeping Cultures Alive: Archives and Indigenous Human Rights*, 2012; *Library Quarterly Special Issue on Diversity and Library and Information Science Education,* 2013), conference presentations and keynotes (Noble 2015, Matienzo 2015, Cole 2015) such as held by the Society of American Archivists, and current CFPs, such as those of *Digital Humanities Quarterly*, *Archives*, and *ALISE*. New interdisciplinary projects focus on building new methods and tools for archiving media content as a corrective to past silences in the archive (Documenting the Now, Social Media Archives Toolkit, Documenting Ferguson, Our Marathon, to name a few). This work suggests more challenging questions: What ethical decisions inform the dissemination of digital collections? How are naming and representation in our information systems influenced by power? When tools and interfaces guide interactions with documents and items, are those interfaces responsive to community needs, or do they force a diversity of ideas into ill-fitting boxes?

To engage with these issues and inform the toolkit we plan two forum events at which we seek to gather a diversity of perspectives and input on the questions above. The first forum will be held in October 2017, and our preparation for that event will involve a detailed scan of existing LIS and museum pedagogy in the areas central to our focus, and an examination of existing project methodologies and processes. We will also develop a set of design provocations, discussion questions, and a reading list. The poster will present the results of the environmental scan, the design prompts, reading list, and discussion questions for the opening forum, and the preliminary design ideas for the toolkit for critique and commentary by DH2017 conference participants. Our goal for the project is to involve diverse community input at every stage of the design, and this poster represents the first step in that process.

Dans cette présentation, nous nous proposons d'analyser la chaîne éditoriale de production et de diffusion des revues savantes en Sciences humaines francophones, en nous appuyant sur le corpus diffusé par la plateforme Érudit. Nous montrerons les limites et les problèmes que présente une telle chaîne éditoriale, pensée à la fin des années 1990, et qui n'a depuis fait l'objet que de très peu de modifications majeures et nous présenterons l'éditeur de texte Stylo, la solution proposée à ces problèmes par l'équipe de la CRC sur les écritures numériques.

Absolument fondamentale en vue d'une diffusion numérique, la structuration des documents et leur balisage sont actuellement reportés à la fin du processus éditorial (l'encodage XML est pris en charge par l'équipe d'Érudit) quand en réalité ceux-ci devraient être envisagés dès la production (par l'auteur lui-même, dès la première révision des articles). À cet égard, il semblerait urgent et logique de réintégrer le travail de balisage et de structuration en début de chaîne.

Un tel objectif se heurte cependant au manque de compétences suffisantes de la part des auteurs : les pratiques d'écriture, telles qu'elles existent aujourd'hui, demandent en effet aux chercheurs de traduire leurs connaissances sur le sens des contenus (ce qu'est une référence ou un titre, l'importance d'un mot, etc.) en simples marques graphiques (italiques, gras, type de guillemets, etc.). Or des erreurs se glissent régulièrement au cours de ce processus du fait du recours à des solutions qui ne sont ni tout à fait spécifiques ni tout à fait explicites, soit finalement à faible valeur de scientificité.

Par ailleurs, ce texte formaté graphiquement est actuellement retravaillé en bout de chaîne par Érudit qui cherche à réinterpréter le sens du texte, à partir de ces indices graphiques. Érudit entreprend alors de transformer ces signes graphiques en balises sémantiques : cette espèce de rétro-programmation implique une perte de temps faramineuse ainsi qu'une potentielle perte d'informations problématique d'un point de vue scientifique.

Pour y remédier, notre équipe est en train de développer l'éditeur de texte Stylo. La philosophie de Stylo consiste à remettre dans les mains des chercheurs la gestion du balisage en partant cette fois-ci de leurs compétences, qui sont des compétences sémantiques plutôt que graphiques. Conçu sur le principe d'un éditeur WYSYWYM (what you see is what you mean), Stylo a le potentiel de changer l'ensemble de la chaîne de production des contenus dans le domaine des revues savantes en Sciences Humaines, en proposant une interface uniformisée et sans perte de données, depuis la rédaction jusqu'à la diffusion, en passant par l'évaluation, la correction et l'édition.

L'éditeur propose aux auteurs un environnement d'écriture très simple mais permettant un enrichissement sémantique à travers des fonctionnalités de balisage léger mais spécifique au travail d'auteur. Le chercheur a ainsi la possibilité de baliser l'ensemble des informations qu'il produit de façon sémantique (titres, sous-titres, références bibliographiques, notes, index), simplement en sélectionnant les éléments, en leur appliquant des styles préprogrammés, ou selon les compétences de l'auteur, en utilisant le format markdown.

La suite de la chaîne éditoriale (évaluation, édition, diffusion) est assurée au sein du même outil, permettant aux producteurs de contenus – les éditeurs de la revue ou de la plateforme de diffusion, ou encore directement les chercheurs eux-mêmes – d'enrichir le texte en sélectionnant et ajoutant des métadonnées (mots-clés, nom de l'auteur, nom de la revue, etc.) et en les alignant avec des autorités.

Les métadonnées, étant alignées, pourront être facilement mises en relation avec d'autres contenus existants (traduction automatique en plusieurs langues, notamment, en se basant par exemple sur les alignements des vocabulaires RAMEAU de la Bnf et LCSH de la Library of Congress). Grâce à l'alignement avec des autorités, les contenus créés via Stylo pourront par ailleurs être mis en relation avec n'importe quels autres contenus – par exemple via un moissonnage qui interroge les autorités, ou encore être mieux indexés par les moteurs de recherche spécialisés.

N'importe quelle plateforme de diffusion peut ainsi exploiter les contenus produits par Stylo. La brique logicielle centrale communiquera via une API avec plusieurs plateformes en fournissant des métadonnées très riches, sans que l'enrichissement soit réalisé par le diffuseur ou l'exploitant final – puisque pris en charge directement par le producteur.

Dans l'esprit des éditeurs WYSIWYM, le formatage graphique du contenu est automatiquement effectué lors de l'export, en s'appuyant sur des modèles programmables et intégrés à la chaîne éditoriale des revues et des plateformes de diffusion (Erudit.ca, Openedition.org).

1. Ces exports pourront être de plusieurs types selon la diffusion visée :
2. des fichiers XML selon les schémas sélectionnés (Erudit, TEI, etc.)
3. des fichiers HTML pour publication directe sur des CMS (grâce à des API)
4. des fichiers print (.pdf) stylés selon des modèles programmables.

L'éditeur pourra être utilisé pour différents types de contenus, notamment :

1. les articles de revues
2. les monographies
3. les mémoires et les thèses
4. les billets de blogue de recherche

Au moment de cette soumission, nous disposons d'un prototype de l'éditeur, dont une version stable est prévue pour le mois d'avril 2017.

Introduction

HumaReC is a Vital-DH@Vital-IT project funded by the Swiss National Foundation that began on October 1 2016, and will run for two years. The research question of HumaReC is to investigate how Humanities research is reshaped and transformed by the digital rhythm of data production and publication. We use as test-case the edition and the study of a unique trilingual Greek, Latin and Arabic New Testament manuscript known as Marciana Gr. Z. 11 (379). This poster presents intermediate results of our research. For more project details, refer to our open research platform Humarec.org , where HumaReC's research is published.

Change–of–Rhythm in Humanities Research

A two to three years' research project in the humanities has traditionally been characterized by the writing, editing and publication of a printed book. This final step would often be postponed for a certain amount of time after the end of the project. The reasonably delayed publication of printed books has been perceived, in a certain way, as proof of authentic, well done research, certified by an established book series. Recently, however, the digital turn in the humanities is creating a completely new research paradigm by transforming the scheme and rhythm of research through digital writing material. Publishing formats can be videos, draft papers, social media posts, short syntheses of datasets in blogs – all before the research is even completed and peer-reviewed. Certified journals like the New Testament Studies now allow articles to reference blogs of individual scholars (Gathercole, 2015). The peer-review process is becoming a continuous process, rather than a unique event, and is increasingly based on "community-based-filtering" (see Fitzpatrick, 2009) due to the spreading use of open repositories such as HAL for the SSH (Centre pour la Communication Scientifique Directe, 2016) or arXiv for the life sciences (Cornell University, 2016).

"Rhythm" is the key-concept through which we observe the changes happening in DH research. According to Henri Meschonnic's analysis, digital writing reminds one of the presence of orality embedded in any kind of written discourse. Meschonnic considered that writing is not opposite to orality but rather includes it, similarly as sense includes sound (Meschonnic, 1995). For him, orality remains inscribed in writing itself, and this relationship can be expressed by the word "rhythm", since the subject who is speaking always remains related to a performance, to a social act. The speaking subject consists of a "body-social-language", in writing as well as in speaking (Meschonnic, 1982). Thus, rhythm can be used as a key for the mapping of our analysis of the transformations happening in DH: the rhythms of data production, data mining, data editing and publishing; the rhythms of reading, peer-review, echoes and discussions about research.

Continuous publishing as new practice in Humanities

Influenced by the Meschonnic approach, we chose rhythm as a central notion in building the structure of HumaReC: a temporality, based on 24 months, which integrates the diverse levels and parts of the project. A new life sciences journal, *Sciencematters*, is driving a revolution and was a major inspiration. Led by Lawrence Rajendran (Zürich, CH), *Sciencematters* argues that "stories can wait, science cannot" (2016). This outlook allows for the publication of many kinds of data, and fosters the fast publication of small datasets before they are integrated into the "full story" of an article. Following this approach, data relating to our project are published continuously on our open research platform. We want to test two levels of publication in our website, on a small scale:

1) Continuous publishing of small datasets that can be corrected and discussed. This includes short blog articles on current research activities and the publication of new folios of the manuscript (part of HumaReC is a manuscript viewer that displays images and transcription of the three languages). In addition to traditional interactive tools as a forum, we are currently implementing an annotation tool that allows users to comment directly on the manuscript transcriptions.
2) Releases of peer-reviewed fixed data. At four stages that have been preset since the launch of HumaRec, the material will be peer-reviewed by an international board and expanded in a written form best described as a "webbook", as well as an eTalk, a multimedia form of publication that has been developed in Vital-IT.

In addition, we will test different rhythms for transcribing and encoding the manuscript by combining methodologies via automated handwritten text recognition (HTR) using the *Transkribus* tool (Transkribus, 2016).

Our poster will present the data process of the project and the different sections of the platform, listing the research methodologies and the IT challenges of each, as well as their links to Humarec.org.

Temporal loci and mixed reality: an experiment in diversifying visualizations of time and space

Celeste Tường Vy Sharpe
csharpe@carleton.edu
Carleton College, United States of America

Sarah Calhoun
scalhoun@carleton.edu
Carleton College, United States of America

Andrew Wilson
awilson@carleton.edu
Carleton College, United States of America

This poster explores ways to use augmented reality to represent complex notions of temporality. Calls for diversifying the digital humanities by scholars like Alan Liu, Amy Earhart, Jessica M. Johnson, and Adeline Koh have called attention to the ways in which digital humanities inquiry and tools often struggle to represent diverse artifacts, cultures, and experiences. Spatial inquiry is one area where scholars are critically engaging and presenting layered analyses of space. Temporality, on the other hand, has received significantly less attention. Notions of time vary widely across cultures. Temporal metadata in digital humanities projects such as timelines or visualizations, however, is frequently constrained by the narrow, linear Gregorian conception of time crystallized by the International Organization for Standardization standard 8601 (ISO 8601).

Using Keith Basso's description of temporal loci of events from his 1996 book *Wisdom Sits in Places*, we can see how myth ("in the beginning"; atemporal) and saga ("modern times"; time described by ISO 8601) frequently overlap and intertwine with each other (50). For instance, in the Thai Buddhist temple paintings that Sandra Cate describes in her 2003 book *Making Merit, Making Art* ("The Defeat of Mara and The Enlightenment (Panya)," plate 10) we can see the convergence of multiple different conceptions of time. One striking piece of a mural captures a moment in time after the recently enlightened Buddha defeats the demon Mara, and a cleansing flood washes away the Mona Lisa and a space shuttle. Attempting to fit the complicated relationships displayed in this image into a simple Dublin Core temporal coverage field would be quite difficult, if not impossible.

We identify two main problems that this initial experiment will address. The first is the issue of visualizing multiple temporalities. Our motivating questions are: what are the visual and spatial relationships between the chronological story of the Buddha defeating Mara given how some Buddhists believe that the Buddha is personal and eternal and always present throughout time? How is that expressed in the mural through a wide range of artistic styles and historical references? These questions will be answered through the course of our research.

The second problem is a more practical question of how to use augmented reality to further research and teaching of these complex cultural concepts when both the visual and technical resources are limited. We intend to use the extant low-res photographs available of the "Defeat of Mara" temple mural and Vuforia to create a cross-platform experience of the religious expression. This will allow users to see and select individual elements in the mural (such as the Mona Lisa or the spaceship) and engage with the different ways one can order and make meaning out of the varied chronologies and temporal references. Vuforia allows us to use an existing framework that has the benefit of being accessible on multiple platforms. We believe this is necessary for facilitating the adoption of augmented reality for classroom and preliminary research uses.

Our poster will outline our theoretical framework, detail our development process using the augmented reality framework Vuforia, and provide possible avenues for further lines of inquiry and applications for temporal visualizations. We'll include static images of the AR experience, as well as ways to access our project remotely.

Long-term outcomes of humanities higher and further education in England and Wales

Nicola Jane Shelton
n.shelton@ucl.ac.uk
University College London, United Kingdom

This paper uses a linked decennial census digital resource (CeLSIUS) from England and Wales supported by funding from the ESRC of interest to the digital humanities community. Publication analysis has shown less use by historians and other humanities researchers, than geographers and other social scientists. This paper introduces the data set and some new research exploring the long-term outcomes of humanities graduates who were resident in England and Wales in 1971 and / or 1991.

Graduates in humanities have lower salaries and lower employment rates in the UK than graduates in medicine and science (ONS, 2013).

But does this affect long term outcomes? The ONS Longitudinal Study for England and Wales (ONS LS) gives us a unique opportunity to study the economic and health outcomes of graduates by university discipline studied. The original sample for the ONS LS was drawn in 1974 (OPCS, 1973) from individuals recorded in the 1971 England and Wales Census. The sample was drawn by selecting four birth dates, giving a sampling fraction of 4/365, or 1.1% of the population of England and Wales, these birth dates are not disclosed. The 1971 sample consisted of around 500,000 people [age 0+], with a similar number of persons (allowing for overall population growth) being sampled at each subsequent census. Sample members are included in all censuses for which they are present and enumerated. More than 200,000 people have been enumerated in five successive censuses (from 1971 to 2011) (Lynch et al, 2015).

In the transition between any two consecutive censuses, some sample members will be lost to the sample either through death or emigration, whilst others will be added to the sample, through birth or immigration. Thus, any child born with an LS sample birth date will automatically become a sample member; similarly someone entering the country (once they enter in to the NHS registration system) with an LS sample birth date will become a sample member. Successful linking clearly depends on the individual being included in the census data capture, and therefore people may effectively leave or enter the record set through enumeration or failure to be enumerated in the census. Blackwell et al (2003) reported tracing rates from 1971 through to 2001 for the ONS LS. These varied from 98.4% in 1991 to 99.3% in 2001; the tracing rate in 2011 was 98.8% (Lynch et al., 2015) which is very high for longitudinal follow up.

All adults with a post age 18 qualification were asked the title of the course, the subject they studied, the year they obtained the qualification and the institution at which they studied, in both the 1971 and 1991 censuses. This is very detailed, offering up to six write in options for subject and has been grouped by ONS into 186 subjects in 1971 and 111 subjects in 1991. Overall participation in higher education in the UK increased from 3.4% in 1950, to 8.4% in 1970, and 19.3% in 1990 (Bolton, 2012). The 1971 respondents will include adults who gained their degrees over their lifetime (so potentially back to the late 1800s). The 1991 graduates will also include anyone with a degree who was enumerated in 1971 and was present and successfully linked in 1991, and also new graduates since 1971 and any immigrants since 1971 who had or obtained a degree prior to the 1991 Census.

In all Censuses occupation (current and for those not employed most recent job and year last worked) is also asked.

In the 1991, 2001 and 2011 Censuses questions about health were asked: general health 2001 onwards and limiting long term illness 1991 onwards. As well as census data, the ONS LS contains linked data on death registrations of sample members.

This paper will examine the employment, health and mortality outcomes for graduates by subject area (humanities, arts, sciences, social sciences) in England and Wales at two time points taking into account age and time period of study. A priori it is expected that those from science disciplines should experience better health outcomes not least due to employment advantages.

Collocations and Network Structure as Insights to Functional Elements of Building Adaptive Capacity

Anne R. Siders
siders@stanford.edu
Stanford University, United States of America

Introduction

Decades of field research have identified numerous characteristics and conditions, so-called “determinants,” such as education, wealth, social networks, government transparency, gender, and risk-communication (Brooks et al. 2005; Smit & Wandel 2006; Tol & Yohe 2007), that affect the ability of individuals and groups to prepare for and respond to the effects of climate change. But why these particular determinants and how do they affect our capacity to adapt?

We apply methods from computational text analysis (Sinclair 1991) and network analysis (Brandes 2001; Blondel et al. 2008) to offer an innovative approach to understanding the concept of adaptive capacity. Computational analyses allow us to reveal the unconscious rhetoric of adaptive capacity that illuminates how determinants are interconnected and how they might work to build adaptive capacity. These patterns are not stated or visible in a single study but emerge from a field-wide analysis. Results depict a concept map of adaptive capacity that operationalize the academic discourse and highlights points of convergence and divergence to inform future research.

Corpus and Methods

A Web of Science search for title = “adaptive capacity”, years 1800-2015, returned 448 non-duplicate English language academic articles. Based on title, journal, and abstract, we categorized papers as focused on social (e.g., community, organization, government; n=295) or non-social systems (e.g., biological, engineering; n= 153). Of 295 social papers, 261 full length texts (88%) were accessible. Most (91%) were published post-2001, when the Intergovernmental Panel on Climate Change (IPCC) first recognized adaptive capacity as a major element of vulnerability to climate change (IPCC 2001), signaling the concept’s rise to the forefront of climate and sustainability research.

We used collocation analysis to develop a network of determinants that visualizes inter-connections and may be interrogated. Based on a close reading, we identified 164 determinants of adaptive capacity and 351 related terms (to account for regional spelling variations, synonyms, gerunds, etc.). Collocation analysis was used under the theory that two concepts whose terms frequently co-locate have a conceptual relationship. Collocates were identified in symmetric 15 word distance with significance of 0.01 using a Fisher’s Exact Test.

Measures of network structure, such as centrality and modularity, have been found in other fields to provide insights into functionality (Krackhardt 1990; Danon et al. 2005). Collocations between determinants were visualized as a network (149 nodes, 1877 edges, network density 0.09). Both degree and betweeness centrality (Brandes 2001) were calculated. The centrality of a determinant may provide insight as to its role and sphere of influence. Community detection (Blondel et al., 2008), which has been shown in other cases to reveal functional groups (Danon et al. 2005), was performed 10 times each at three resolutions (0.4, 0.7, 1.1) (Lambiotte et al. 2008).

Results

Results provide substantial insight into potential roles for determinants. In many cases, results confirm expectations and establish consensus. In others, results raise new research questions and may provide an impetus to test assumptions currently held within the field. Results further suggest determinants group into hierarchical functional modules, which could provide a function-based framework to assess adaptive capacity. These patterns may also reconcile competing theories in adaptive capacity literature as to whether all determinants are critical or some may compensate for weaknesses in others (Tol & Yohe 2007).

L'accès vu comme une contrainte et un défi : le processus de naissance d'une base de données

Pinelopi Skarsouli
pinelopi.skarsouli@cnrs.fr
National Center for Scientific Research (CNRS), France

Dina Bacalexi
dina.bacalexi@cnrs.fr
National Center for Scientific Research (CNRS), France

Une base de données organise la connaissance en vue de son utilisation par un public donné. Cette définition trop rapide et lacunaire ne tient pas compte de la complexité du processus de création, ni de la véritable nature d'une base numérique, qui, pour nous, doit être le fruit d'un dialogue entre la partie scientifique et la partie technique du projet. Nous allons étudier, pour deux bases antiquisantes, le processus de passage d'une approche textuelle, libre de toute contrainte, à une autre basée sur la structuration, c'est-à-dire la transcription en structuration formelle des décisions prises par les analystes des textes antiques.

Dans ces deux cas, un nouvel accès, résultat de la restructuration des outils, vise un public nouveau tout en servant mieux l'ancien :

1) l'abandon d'un modèle conçu pour l'imprimé, où la recension annuelle des données pour produire le volume papier de *l'Année Philologique*, accompagné d'une transformation en site web, constituait pendant des décennies le but recherché : l'objectif était un changement total du contenu et de la structure, pour obtenir une véritable base de données, tout à fait différente (*IPhiS,* la nouvelle base philologique en construction).
2) la transformation d'un modèle sans volume papier paru, qui n'était pas pour autant une construction « native numérique » mais un simple export html périodique d'un ensemble de données thématiques : l'objectif était la reprise des anciennes données avec une modélisation nouvelle permettant d'obtenir une nouvelle base, qui continuerait l'ancienne seulement en ce qui concerne le contenu (le cas du *Répertoire des sources philosophiques antiques*).

La question de l'accès libre aux données s'est posée à nous comme une contrainte. Notre travail d'antiquisants analystes de sources grecques et latines philologiques ou philosophiques (au sens large des termes) a croisé celui des développeurs d'applications numériques quand nous avons commencé à transformer les deux outils bibliographiques précités. Il existe plusieurs façons d'envisager la perméabilité et l'articulation scientifique-technique ; nous étudierons comment le dialogue permanent direct permet un meilleur accès aux données d'une base.

Quand un modèle a fait ses preuves depuis près de 80 ans et que sa notoriété est installée dans la communauté, la difficulté est d'imposer un modèle nouveau quant à la pertinence scientifique et le traitement de l'information. La contrainte est double : passer d'un logiciel propriétaire (4D) dont l'adaptation convenait tout à fait à la bibliographie papier et à son export en ligne, à une solution de logiciel libre qui apporterait cependant la même richesse et finesse d'indexation que 4D et créerait une véritable base de données numérique. La question ne concernait pas seulement le développement de l'outil nouveau, mais aussi le type des données à implémenter dans la base. Notre questionnement concernait aussi le fait même de rendre la base accessible librement sur le web : au moment de la prolifération de l'information grâce aux moteurs de recherche généralistes du type *Google scholar*, quelle serait la « plus-value » d'une énième base ? C'est pourquoi nous avons commencé à réfléchir comment les entrées de la base pourraient pointer vers des données textuelles littéraires extérieures en XML/TEI, afin que nos bases ne soient pas simplement des *thesauri* bibliographiques riches et bien ordonnées, mais sans lien avec les sources qu'elles sont censées analyser. Cette question est pour l'instant pour nous au stade de la réflexion théorique.

La liberté d'accès, dans le cadre des disciplines rares comme les nôtres, pose la question de la protection contre le copiage, le plagiat, l'imitation et donc l'appropriation de notre travail. C'est pourquoi, dès le début du projet, il est important de choisir une licence adaptée, par exemple de la famille *Creative Commons.* Il faut aussi envisager l'*accessibilité effective* des données *via* l'interface utilisateur et le respect des standards du web.

Nous constatons trop souvent que les bases de données, sites collaboratifs, plateformes, éditions etc. émanent de programmes limités dans le temps, au financement et au personnel précaire, ce qui impacte la réalisation des projets dans les délais impartis. Or, si ces bases répondent à une demande d'accès à des données fiables et de qualité contrairement à la masse incontrôlée offerte par les moteurs généralistes du web, elles ont vocation à durer et ont besoin d'une mise à jour régulière de leur contenu et de leur infrastructure logicielle pour remplir leur mission. Les changements de technologie (internes ou imposés par l'écosystème) peuvent comporter des risques pour les projets et leurs utilisateurs finaux. La disparition des outils entraîne souvent celle du savoir et du savoir-faire des personnels.

La nécessité d'obéir aux injonctions du court terme impacte le travail de renouvellement des anciennes bases : les délais de transformation sont plus longs que prévu, puisqu'il faut d'abord passer par une expression de nouveaux besoins et ensuite par une modélisation tenant compte des choix scientifiques et traduisant ceux-ci en solutions techniques ; il faut ensuite expérimenter, adapter, affiner. Un tel fonctionnement est à l'opposé d'une demande de solution rapide clés en main.

L'implémentation des notices dans une base en flux continu sur le web (en vue de leur moissonnage par les moteurs de recherche en temps réel), le rêve d'exhaustivité, contribuent à alimenter l'idée de liberté totale individuelle qui va à l'encontre du mode de travail collectif. Le risque est d'instaurer une nouvelle forme de dépendance et de contrôle généralisé, voire d'accélération des cadences et de fin programmée de toute vérification de la pertinence scientifique. C'est tout à fait différent d'une base de données participative et basée sur la contribution de la communauté.

Le travail sur le contenu d'une base dépend aussi de l'élaboration d'un cahier de charges, de la modélisation des données (qui définit à son tour le type d'accès aux données dans l'immédiat mais aussi dans l'avenir), des formulaires permettant de la remplir, de son interface de consultation et de la constitution d'une communauté d'utilisateurs. La question est la (re)structuration et la (re)présentation des données sous une nouvelle forme en ligne, qui tienne compte des standards actuels (libre accès, interopérabilité etc.). La normalisation des données et la réduction de la redondance de l'information sont des gages d'une base de données pleinement accessible et exploitable par ses utilisateurs.

Modeling Student Authorship: The Rhetoric of Markup in the Writing Classroom

Kevin G. Smith
kgsmith2@gmail.com
Northeastern University, United States of America

This poster reports on research that examines the use of XML markup for student authoring, a marked shift from the mimetic roots of XML and its primary use in digital humanities research, the TEI. Thus far, two courses have been taught with a total enrollment of 35 students (19 students in advanced writing for the technical professions, Summer 2016; 14 students in first-year writing, Fall 2016). The research questions are: How does markup function rhetorically when used for authorship? Does writing in XML and designing schemas for authoring contribute to students' understanding of their writing and reading processes? Do reading and writing practices in the markup classroom transfer to other contexts?

These research questions present unique methodological concerns for the study of markup. How can we make claims about the rhetorical and expressive capacities of *authorial* markup? How can we better understand the role of the schema, the markup, and the platform(s) in students' writing, reading, and thinking processes? In short, how do we study this? These questions will animate the presentation of preliminary results, the subject of the poster.

There has been considerable interest in the semantics of markup languages at recent TEI (Ciotti & Tomasi, 2014; Eide, 2013) and DH conferences (Sperberg-McQueen Marcoux, & Huitfeldt, 2010, 2014), most of which has centered around formal approaches to modeling semantics to explicate the meaning of markup (Sperberg-McQueen, Huitfeldt, & Renear, 2000). A related thread of markup research has examined the rhetorical and expressive capacities of markup (Flanders, 2004; Flanders & Fiormonte, 2007), growing out of an understanding of markup as not merely descriptive, but also interpretive and, indeed, performative (Renear, 2000). Though Wernimont and Flanders (2007) have discussed the potentials of authorial markup to expand our shared notions of scholarly communication, markup in this authorial realm remains rarely used (one exception being the work of Desmet et al., 2005) and even more rarely studied in a systematic way. This poster will present preliminary results from just such an attempt—a sustained study of an experimental approach to XML as a technology for the production of texts.

The production of texts, in this case, was undertaken by two cohorts of undergraduate students. In addition to writing their assignments in XML (using Oxygen), these courses engaged students in a semester-long, collaborative writing project: the design and implementation of a custom XML schema that structurally and rhetorically models a range of genres of writing. Pedagogically, this approach aims to foster the close attention and metacognition often cited in classroom-oriented uses of XML/TEI (e.g., Singer, 2013; Conatser, 2013). Where this approach to markup differs from earlier uses, however, is in the thoroughly bottom-up, data driven approach to schema design (Piez, 2001). Students begin with a (basically) bare schema and—iteratively and deliberately over the course of an entire semester—design and revise the schema for a range of writing tasks using document analysis and modeling, qualitative writing research methods, and their own experiences of authorship.

To research these classes, I employed a teacher research methodology—a systematic approach to data collection that **honors the inside perspectives of teachers and students**—that adapted qualitative research methods culled from ethnography, education, and writing studies research. Data was gathered from direct participant observation, reflective journaling, qualitative interviews (three interviews each with nine case study students), survey, and the collection of student writing (normal prose and XML, including version control logs for all XML files). Teacher research foregrounds and honors the experiences and perspectives of students as they compose; thus, the particular methods deployed in this study concern writing as a process, rather than as a static product. This methodology aligns with research in rhetoric and writing studies, which, fundamentally, understands "writing (and broader rhetorical practice) as a verb rather than a noun" (McNely and Teston, 2015: 115).

Preliminary results from the study speak to 1) how students develop and operationalize genre knowledge; 2) the rhetorical constraints and affordances of schema design as collaborative writing; and 3) markup's reported intervention into students' thinking and writing processes.

This poster frames this research study as a case study, a demonstration of the kinds of insights that systematic, qualitative research into markup can foster. It aims to organize the audience around a series of questions, including: How are rhetorical theories pertinent to our examination of DH tools and methods, particularly those of data modeling and representation? How does the study of student writing/authorship necessitate a willingness to invent methods sensitive to, and emergent from, particular sites of research? What methodological (re)orientation does an expansion of our disciplinary objects of inquiry require? These questions are best explored interactively, through the dynamic presentation of data generated through this research, and an exploration of the opportunities and limitations of this qualitative approach to markup research.

The VSim Repository and Archive: Knowledge Mobilization for 3D Research

Lisa M. Snyder
lms@ats.ucla.edu
UC Los Angeles, United States of America

With the explosion of academic interest in 3D modeling and interactive environments, two questions dominate: How can scholars and educators access these models? And how can they be integrated into the classroom? Enter VSim – a much-needed software interface for academics exploring applications for 3D computer models in humanities research and teaching – and the VSim Repository and Archive, both now available through the UCLA Library.

VSim is an easy-to-use software interface that allows real-time exploration of highly detailed, academically generated 3D computer models in both formal and informal educational settings across grade levels and humanities disciplines. The VSim Repository and Archive provides a platform for the dissemination of academically generated 3D content.

This poster presentation is both a launch announcement and a solicitation for submissions from content creators. If you are working in 3D, please consider sharing your projects for teaching and learning through the VSim Repository and Archive.

Ghostwriter identification in Yasunari Kawabata's works in the 1960s

Hao Sun
sonnkou1985@gmail.com
Doshisha University, Japan

Mingzhe Jin
mjin@mail.doshisha.ac.jp
Doshisha University, Japan

Introduction

Yasunari Kawabata was a Japanese novelist who received the Nobel Prize for Literature in 1968. He was famous for his masterpieces such as *Snow Country*, *The Sound of the Mountain*, *The Old Capital*, *House of the Sleeping Beauties,* and so on. Kawabata had a shattered childhood. He was orphaned at five years old, and his other relatives including his grandfather, grandmother, and elder sister also passed away before he was fourteen. The successive deaths of his loved ones induced mental problems, which became worse in the 1960s. He became addicted to sleeping pills during those years. However, two of Kawabata's masterpieces *The Old Capital* and *House of the Sleeping Beauties* were published during his sleeping pills addiction period. These two novels were suspected as having been written by ghostwriters because it was hard to imagine that Kawabata could continue writing novels in his mental condition. There are already some pieces of evidence for the ghostwriter issue of *The Old Capital* and *House of the Sleeping Beauties*. Kawabata sent a letter to Sawano before the publication of *The Old Capital*. In the letter he wrote: "I have accepted to write a novel about Kyoto; the deadline is approaching but I even don't know how to start. Sawano was surprised when he received this letter. He went to Kyoto to meet Kawabata and gave advice on how to write *The Old Capital*. Itasaka mentions in his book that *The Old Capital* and *House of the Sleeping Beauties* were actually written by ghostwriters (Itasaka, 1997). *The Old Capital* may have been written by Kawabata's three disciples whose names are Hisao Sawano, Makoto Hokujyo, and Yukio Mishima. *House of the Sleeping Beauties* may have been written by Yukio Mishima. In this study, we show strong evidence suggesting the real author of *The Old Capital* and *House of the Sleeping Beauties* from a data analysis approach.

Method

The method of this study includes three main steps. Firstly, we digitized more than ten novels of both Kawabata and the three possible ghostwriters. Then, we extracted stylometric features from the novels, and all chapters of *The Old Capital* and *House of the Sleeping Beauties*. Finally, we applied the unsupervised and supervised methods to infer the possible author of *The Old Capital* and *House of the Sleeping Beauties*.

We used bigrams of characters and punctuation marks, part-of-speech bigrams, and phrase patterns as stylometric features, which have been proven useful in Japanese authorship attribution (Matsuura and Kanada, 2000; Jin, 2003, 2013).

Bigrams of characters and punctuation marks are pairs of two adjacent characters or punctuation marks extracted from plain text. Japanese texts should be tokenized previously for the extraction of part-of-speech features. We applied the Japanese morphological analyzer called MeCab to separate a Japanese sentence into morphemes. MeCab outputs the parts-of-speech of words in several layers. Deeper layers process more detailed information. In this study, we use information from the first layer. As an example, part-of-speech bigrams in the Japanese sentence “Ronbun wo kaku.” are “Noun_Particle,” “Particle_Verb,” and “Verb_Period.”

Phrase pattern is a powerful feature that can be extracted in terms of syntax. A Japanese parser (CaboCha) was introduced to separate sentences into phrases. Phrase pattern is defined as the smallest unit that divides the sentence into unnatural parts (Jin, 2013). It is a combination of two parts. One is the original form of the particles and punctuation marks, while the other is the parts-of-speech of the other materials, except for the particles and punctuation marks in the same phrase. The two phrase patterns in the sentence “Ronbun wo kaku.” are “Noun_wo” and “Verb_Period.”

We applied unsupervised methods and the integrated classification algorithm in this study. The idea of the integrated classification algorithm was to combine the results of several stylometric features and classifiers. It achieved highest classification accuracy in authorship attribution of literature (Jin, 2014). The integrated classification algorithm combines the results of stylometric features and classifiers to avoid the bias under a majority vote rule. AdaBoost (ADA), High-dimensional Discriminant Analysis (HDDA), Logistic Model Tree (LMT), Random Forest (RF), and Support Vector Machine (SVM) were used as the base classifiers.

Results

The result of *House of the Sleeping Beauties* reveals that compared to Mishima, all chapters of *House of the Sleeping Beauties* are more likely to be written by Kawabata. The result in the classification between Kawabata and Hokujyo shows that the writing style in all chapters of *The Old Capital* is more like Kawabata’s.

Access to DH Pedagogy as the Norm: Introducing Students to DH Methods Across the Curriculum and at a Distance

Dan Tracy
dtracy@illinois.edu
University of Illinois at Urbana-Champaign
United States of America

Elizabeth Massa Hoiem
hoiem@illinois.edu
University of Illinois at Urbana-Champaign
United States of America

This poster presents research into integration and assessment of digital humanities pedagogy in a distance course on the History of Children’s Literature, and provokes conversation about pedagogical approaches that expand student access to DH methods, tools, and dispositions. Much of the existing literature on DH pedagogy addresses methods courses or multimodal writing courses rather than integration of DH practices in particular topical contexts, or advanced topics courses that explore a narrow slice of disciplinary content through extended engagements with digital projects (Ball 2012; Mostern & Gainor 2013; Fyfe 2016; Nyhan, Mahony, and Terras 2016). This literature provides valuable lessons but raises questions about the feasibility of engaging with DH across the curriculum in small-to-medium scale engagements with new methods and technologies. Amy E. Earhart and Toniesha L. Taylor (2016), for example, respond to this situation by rejecting the idea that DH should be limited to advanced courses and propose broader integration of “embedded [DH] skills development” that students can take out of the environment of a specific institution. Similarly, we suggest that allowing for repeated and diverse engagement by students across methods-intensive and topic-intensive courses (as is now common for writing) is necessary for teaching deeper DH dispositions like collaboration, openness to failure, and creativity with technology.

Simultaneously, the existing literature has focused on residential instruction with access to physical artifacts. This limit is problematic when at least one discipline with a heavy investment in DH, library and information science, is well past transition to a majority distance learning population. LIS programs have developed experience and expertise in teaching technology at a distance, and lessons from these programs may be useful to the DH community. While some teaching goals may only be met in person, others might be achieved through well-structured online learning.

To ground this discussion, the authors, the course instructor, and a subject librarian will present their development, assessment, and rethinking of a multimodal publication assignment using the Scalar platform in a synchronous online course on the History of Children's Literature. Students worked in groups to create a multi-media web resource on "diverse history." The class discussed what is included or omitted from historical narratives, whether they be children's historical fiction or history textbooks, before contemplating this selection process in children's literature itself. The librarian introduced students to the context of DH publishing and Scalar, and to issues related to responsible use of multimedia. Then each group chose an issue related to "diverse history" and built one section of the website. The long-term goal is for successive classes to edit, revise, and expand this project

This collaborative project replaced an assignment from previous years, when students built individual websites about a children's book of their choice. This project maximized scaffolding, with detailed guidance on information students should locate about their books and the final website shape. This iteration of the class took place during a time when distance students came to campus one weekend each semester, and this time was used for in-depth introduction to the array of specialized library resources needed to complete the questions about their book's production and reception. The new assignment sought to re-imagine learning outcomes that would allow students to engage with a particular DH publishing technology, Scalar, and grapple with issues of collaboration and multimodal authoring in a context where the final product was less predetermined. Nonetheless, the elimination of the in person component, which occurred at the same time, removed an obvious "lab" opportunity for learning related technical issues. The pedagogical design involved making the best balance between asynchronous and synchronous activities to compensate for the absence of in person activities. Our evaluation of the success of the assignment relied on assessment of Scalar sample sites and final projects created by the students, as well as on reflective essays written by the students and observations made in the course of student consultations. This evaluation led to ideas for how to revise the course for future semesters to improve learning of collaborative behaviors, openness to failure, and creativity with technology. This includes, most notably, a re-envisioning of how synchronous class time is used in the future.

By sharing our experiences in developing, teaching, assessing, and revising this course in successive iterations, we hope to explore with attendees the ways in which DH methods, tools, and dispositions can proliferate across the curriculum. We will promote discussion of what DH methods, tools, and dispositions can be taught well in different settings, whether that means varying scales of integration in DH classrooms, or exploring what can be taught virtually versus in person.

How Agatha Christie Described Women? : The Behaviour of *She* in Christie's Novels

Narumi Tsuchimura
t.naru.425@gmail.com
Osaka University, Japan

This paper describes a stylometric analysis of Agatha Christie's works with a special reference to the use of the feminine personal pronoun *she* in her novels. In a previous study, Tsuchimura (2016), as a result of the statistical analysis, it is shown that Christie tends to use the word *she* much more frequently than her contemporary Dorothy Sayers, a British mystery writer. She occurs about 12,000 times per million words in Christie's works whereas it occurs about 5,500 times in Sayers' works. A number of characteristic words were identified in the study, and this study focuses on the use of the word *she* in collocations within Christie's works.

It is possible to hypothesize that *she* occurs frequently in Christie's works because although the protagonists in Sayers' works are all male (Lord Peter Wimsey), Christie frequently employs female protagonists (Miss Marple and Tuppence Beresford). In order to test this hypothesis, a Random Forest (Breiman, 2001) classifier is trained on the 500 most common words from all of Sayers' works (55 texts) and Christie's works whose protagonists are not females (173 texts). As is shown in Figure 1, looking at the mean decrease in the GINI importance of the model per word, which measures the relative importance of each word in classifying a text as that of Sayers' or Christie's, the word *she* contributes strongly to classification of texts into

2 groups regardless of the protagonists' gender. We can see that Christie tends to use the word *she* frequently even in the works having or foregrounding male protagonists.

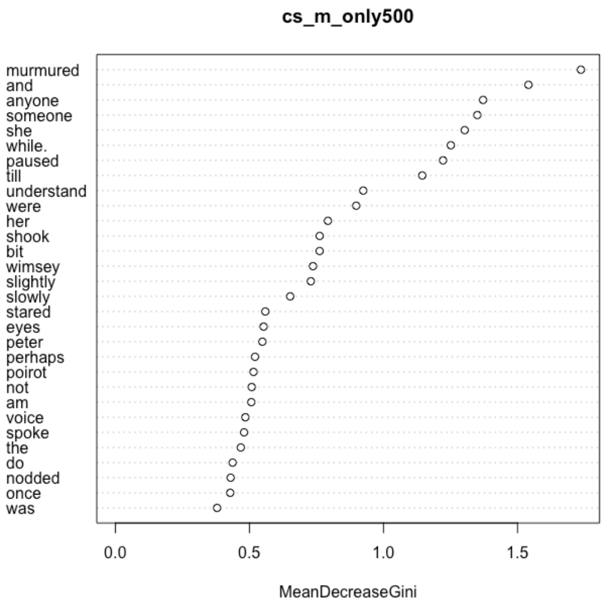

Figure 1. Variable Importance Plot of the result of Random Forests

The question arises as to how the word *she* is used in Christie's novels. To clarify its behaviour, this study examines collocations containing *she* in Christie's works. Following Sinclair and Jones (1974), who state that 'for any node, a very high proportion of relevant information could be obtained by examining collocates at positions N-4 to N+4,' this study deals only with collocates at position N-4 to N+4. From a number of statistical measures commonly used to calculate the significance of collocations, this study chooses the MI-score, for 'MI-score tends to give information about its lexical behaviour, but particularly about the more idiomatic ('fixed') co-occurrences' (Hunston, 2002: 74). The minimum frequency of collocates was set at 10, and the threshold of the MI-score was set at 3.0.

The extracted collocates of *she* in Christie's works amount to 104, when proper nouns are excluded, the number of remaining types of collocates is 79. When compared with collocates of *she* in Sayers' works, those in Sayers' novels are mostly function words. It is thus difficult to see the behaviour of *she* in Sayers' works and in comparison with Christie's works.

When we compare collocates of *she* with those of *he* in Christie's works, we can see stereotypical femininity. The collocates of *she* in Christie works consist of a large number of words related to crying (*sobbed, wept, wailed, screamed, crying*) and actions indicative of fear or sadness (*prostrated, frightens, fainted, shrank, clung, swayed, shivered*). These collocates contrast with those of *he*, which include words such as *hummed* and *laughs.* Moreover, we can see from the collocates of *she* and *he* that it is *she* who is *choked* or *strangled* by a male criminal while it is *he* who *killed* a female. This paper discusses in great detail how Christie describes female in her works from the perspective of collocates of *she*.

nodegoat: Enabling Explorative Research

Pim van Bree

LAB1100, The Netherlands

Geert Kessels
geert@lab1100.com
LAB1100, The Netherlands

Introduction

nodegoat allows scholars to build datasets based on their own data model and offers relational modes of analysis with spatial and chronological forms of contextualisation. By combining these elements within one environment, scholars are able to instantly process, analyse and visualise complex datasets relationally, diachronically and spatially; trailblazing.

nodegoat follows an object-oriented approach throughout its core functionalities. Borrowing from actor-network theory this means that people, events, artefacts, and sources are treated as equal: objects, and hierarchy depends solely on the composition of the network: relations. This object-oriented approach advocates the self-identification of individual objects and maps the correlation of objects within the collective.

Research Environment

nodegoat is a web-based research environment that facilitates an object-oriented form of data management with an integrated support for diachronic and spatial modes of analysis. This research environment has been developed to allow scholars to design custom relational database models. nodegoat dynamically combines functionalities of a database management system (e.g. Access/FileMaker) with visualisation possibilities (e.g. Gephi/Palladio) and extends these functionalities (e.g. in-text referencing, LOD-module) in one web-based GUI. As a result, nodegoat offers researchers an environment that seamlessly combines data management functionalities with the ability to analyse and visualise data.

The explorative nature of nodegoat allows researchers to trailblaze through data; instead of working with static 'pushes' – or exports – of data, data is dynamically 'pulled' within its context each time a query is fired. The environment can be used in self-defined collaborative configurations with varying clearance levels for different groups of users.

As a result of nodegoat's object-oriented set-up, everything is an object. In the case of a research project on correspondence networks, this means that a researcher would define three types of objects in nodegoat: 'letter', 'person', 'city'. Each object relates to an other object via relations (e.g. a letter relates to persons to identify the sender/receiver and this letters has been sent from/received in a city). In an extended research process, researchers could also define themselves as objects in the dataset, their sources or other datasets. Due to the focus on relations and associations between heterogeneous types of objects, the platform is equipped to perform analyses spanning multitudes of objects. By enriching objects with chronological and geospatial attributed associations, the establishment and the evolution of networks of objects is fully contextualised. In nodegoat, these contexts and sets of networked data can be instantly visualised through time and space.

This open-ended approach makes nodegoat different from tools like the Social Networks and Archival Context Project, Alan Liu's Research Oriented Social Environment, the Software Environment for the Advancement of Scholarly Research, Prosop, or tools with a main focus on coding of qualitative data as seen in various computer-assisted qualitative data analysis software. With its object-oriented approach, nodegoat facilitates the aggregation of collections, coding of texts, and analysis of networks, but models these methods towards the creation and contextualisation of single objects that move through time and space.

Facts & Figures

nodegoat is conceptualised and built by the independent research firm LAB1100, based in The Hague, The Netherlands. In order to share the functionalities of nodegoat with the scholarly community, scholars and research institutes are invited to use nodegoat for their own research purposes. Over 300 scholars have a personal research domain on nodegoat.net. Over 15 institutional partnerships have been established with universities, research institutes, and museums in The Netherlands, Belgium, Luxembourg, and Germany.

A nodegoat user forum and FAQ is hosted on the Historical Network Research website. In the course of 2018 an open source package of nodegoat will be released within the wider framework of the nodegoat community.

Digital Humanities at Berkeley and the Digital Life Project

Courtney von Vacano
cvacano@berkeley.edu
UC Berkeley, United States of America

Abigail T. De Kosnik
adekosnik@berkeley.edu
UC Berkeley, United States of America

Stephen Best
sbest@berkeley.edu
UC Berkeley, United States of America

"The Digital Life Project" at UC Berkeley aims to reframe how we define digital humanities by bringing critical analysis to every stage of a highly collaborative and distributed research process. Below, we provide three examples of how this work is evolving at UC Berkeley.

To begin, incidents in the #BlackLivesMatter social movement raised our collective awareness and compelled us to rethink the digital humanities landscape on campus. We realized that understandings of race were being shaped by the dissemination of footage, images, and words. In particular, the dissemination of images of racial violence through media has begun to change the nature of questions in scholarship on race. Questions can no longer overlook a focus on the structure of those sources of data. Furthermore, in this rapid shift, social media must be understood as an infrastructure of hybrid online + offline human existence (i.e., the digital life).

We might perceive the dystopia of digital life in the preponderance of disturbing images of brutality and oppression, an archive that many—including victims of that violence—wish to reclaim. Conversely, we might understand the utopia of digital life to entail the affordance for social media users to document and share their experiences, instantaneously share information, and recruit attention, assistance, and aid to individuals and groups in need. In focusing on the broad rubric of "digital life," moreover, we want to support both dialogue in the broader university community and plans for focused research on a range of issues.

The first example of research within The Digital Life Project is a collaborative endeavor that is embedded in a digital humanities, ethnic studies methods course. Professor Keith Feldman worked closely with both the Ethnic Studies Library and the D-Lab to implement this project that included 65 undergraduate students, two graduate students, and a postdoctoral fellow, in addition to library staff. Students worked with digitized field recordings of events at Berkeley from the late 1960s from the Yuen Archive. The structuring and coding of the audio data went back to (a) all of the students for their individual research papers; (b) the Ethnic Studies Library to help seed a Thesaurus for the Yuen archive; and (c) the public in the form of more user-friendly audio files housed on the Internet Archive. The project impacted multiple constituencies in both immediate and long-term ways. By the end of this course, students were able to historicize the emergence and transformation of the humanities as a field of knowledge, use computational methodologies to conduct research on race and ethnicity, practice various ways to read closely, critically, and against the grain, while at the same time being exposed to the affordances and challenges of digital humanities.

Next, we embarked on a groundbreaking initiative to track and monitor types of Internet-based hate: The Online Hate Index (OHI). The goal is to create a comparative analysis of the online locations, sources, and relationships, and motivations behind online hate targeting different populations. Because of the marked rise of xenophobia in America today, the first installment focused on anti-Latino immigrant sentiments; subsequent studies will examine different forms of targeted hate. The D-Lab provided guidance on designing and implementing a computational research methodology that employed Machine Learning. The League of United Latin American Citizens (LULAC) provided specific information relating to anti-immigrant, anti-refugee, and anti-migrant populations and enabled the project findings to become actionable. In the future, ADL's Center for Extremism and Center for Technology and Society will provide expertise on the online locations and characteristics of hate groups, in-house computing resources, and the techniques used to terrorize groups.

After one year of the Digital Life Project, we reflect upon the lessons learned in generating a new body of research through a highly distributed infrastructure that optimizes (a) the knowledge of graduate students and staff consultants and (b) mentorship within working groups and research teams comprised of undergraduates, graduate students, postdocs, faculty, and staff. At the same time, we are keeping our sights on mobilizing activism in order to foment an activist/researcher stance. Our collaboratory research work clearly defines roles and tasks within the research teams and thereby provides much needed apprenticeship opportunities that underrepresented minorities lack.

Virtual Hamlet: Combining Motion Capture and Real Time Digital Puppetry

Augustus Wendell
wendell@njit.edu
New Jersey Institute of Technology
United States of America

Louis Wells
wells@njit.edu
New Jersey Institute of Technology
United States of America

As a theatrical production, Hamlet poses a particular directorial challenge: the Ghost. How should an apparition be presented onstage alongside mortal characters? Traditional Shakespearean theatre presented apparitions using theatrical effects to visually separate these characters from the mortal characters. Modern theatrical productions must address this same issue with every new staging. Solving this question can help lay a clear conceptual footing for the rest of the production's conceptual considerations. A recent production in New York City in 2015 directed by Austin Pendleton opted to make the Ghost invisible to everyone but those guards who first encounter him, and once Hamlet sees him, only Hamlet. This decision rendered Hamlet mentally disturbed in the eyes of the audience (Isherwood 2017). Kenneth Branagh's cinematic Hamlet in 1996 created a ghost that had a "special effects and a horror-film look." (Maslin 1996) This approach favors brutal realism expected in modern cinema. These two approaches represent extremes in production solutions to the ghost; psychological illness, and pale faces in armor.

When Hamlet was first produced, the Elizabethan stage was full of special effects (Brockett, Franklin 2008). Shakespeare was a practitioner of special effects technology such as pyrotechnics, rope and pulley and trap doors. His commitment to authenticity and effect even led to the accidental destruction of a theater by fire in 1613 after the use of a cannon-based special effect. As conceived by faculty in a theatre program and a digital effects design department at the same university, the challenge of representing the ghost and the Shakespearean spirit of theatrical effect became an opportunity for collaboration. This was our opportunity to create a new type of ghost, one that bridges the traditions of theater and cutting edge interactive media.

Theater has a history of stage projections dating from the 1700's use of magic lantern devices (Figure 1) to the 1920's when innovators like Erwin Piscator began their experiments with the medium (Figure 2).

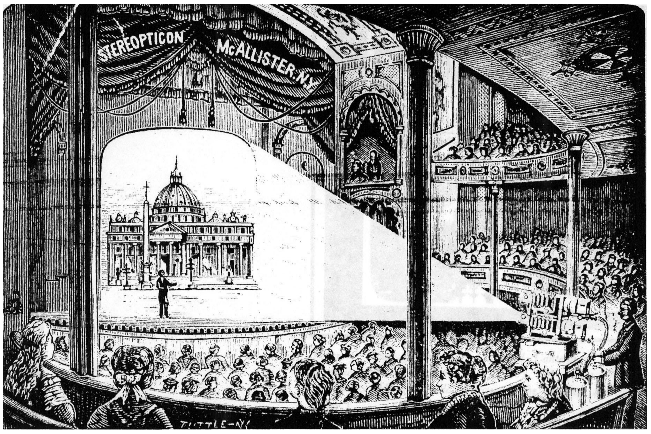

Figure 1. A magic lantern projector device.

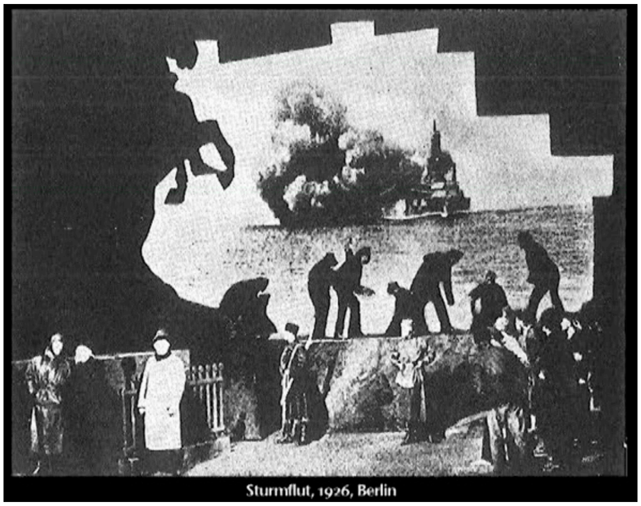

Figure 2. Erwin Piscator staging of *Sturmflut*, 1926 with projected imagery.

Throughout the twentieth century there was an extraordinary growth in the implementation of projections from experimental to mainstream theater (Theatre Communications Group 2011). While the size and complexity of projections has grown over time they have been until recently static or pre-recorded. With emerging technologies such as Microsoft's Kinect Camera and Derivative Software's TouchDesigner projections can be an interactive, responsive addition to the live theatrical experience. Our collaboration utilized these technologies in creation of our ghost.

Theatre has a long tradition of extending the body in performance. Costumes, makeup and prosthetics are the bread-and-butter of the art. Greek theatre used large scale masks and costumes to amplify theatrical expression, while Elizabethan theatre utilized extreme makeup applications and costuming for supernatural characters. Physical puppetry provides a clear mechanism to extend the performative and expressive capabilities of the actor. There are, however, some practical limitations to the physical puppetry approach: the movement and visual effect of the puppet is limited to the physical realities of the performer. Pushing beyond these boundaries, cinema has used digital motion capture to create such characters as Gollum in the Lord of the Rings trilogy and the recent Planet of the Apes films. Andy Serkis, an actor known for his motion captured performances, states, "Performance capture is a tool that allows actors to transform themselves into many different characters. You're not confined by physicality. You can play anything" (Hart 2017). Advances in virtual staging and performance capture, notably used in the production of the film Avatar, have extended motion capture for characters into the real time realm.

Although hybrid physical/digital stagings have been undertaken before (Meador, W. Scott, et al 2009, Bermudez et al 2002), the field has not kept pace with rapidly evolving technology. Our production combined recent advances in inexpensive real-time motion capture with the theoretical underpinnings of theatrical puppetry to perform a spatio-digital character in a live theatrical venue. A Kinect sensor on stage captured the movements of a physical actor performing the ghost. This data was manipulated in Derivative Software TouchDesigner and optically projected as an abstract digital apparition back onto the stage concurrent to the performance (Figures 3, 4). The virtual puppet became at once puppet and avatar, both extending and replacing the physical body of the actor. The dual space of this performance, half body-sized space of the actor and half virtualized space of the projected apparition, plays to the notion of the Cybrid space (Anders 1999).

Playing with Time

Jeri Wieringa
jwiering@gmu.edu
George Mason University, United States of America

The question of change over time is central for historians as they trace the contours of people, communities, organizations, and states. But computationally tracing changes in discourse over time is not a straightforward process with our current algorithmic tools and methods. While charting topics over time can give a general picture of the prevalence of ideas or discourses at various points, Benjamin Schmidt and others have raised concerns regarding the ways existing tools and methods model change over time. Most text-mining algorithms assume that time is linear and progressive, is experienced as such, and that the data is generally consistent over time. As Schmidt notes, even models such as Topics over Time, which was developed to account for shifts in language, are problematic because of the assumptions they make regarding how language changes (Schmidt 2012, see also Underwood, 2012, and Nowviskie, 2016).

If we allow that time is relative and that the experience of time shapes the ways a community and its discourses develop, we are faced with the challenge of how to incorporate varied experiences of time into our computational models. This poster will present my preliminary results applying various periodization schemes to track the development of Seventh-day Adventist discourses around salvation and health over the first 70 years of the denomination's existence.

Seventh-day Adventism is an apocalyptic and millennialist belief system, in that followers anticipate the imminent return of Jesus Christ and the corresponding end of the world. Born out of William Miller's teaching that 1843 (later 1844) would be the date of Christ's return, early Seventh-day Adventists reinterpreted the date in the wake of the Great Disappointment (the period after October 22, 1844, the date the Millerites believed Jesus would return. to signify the start of a new, final, and assumedly short phase in the work of salvation). They also adopted Sabbatarianism, holding Saturday, rather than Sunday, as the proper day for Christian observance. As such, early adherents operated within a changing temporal imaginary, organizing their weeks and years in contrast to their religious neighbors and anticipating, with varying degrees of urgency at different points in their history, the second coming.

The changing constructions of time within Seventh-day Adventism provide an instructive case study for examining how alternative structures and experiences of time might be modeled computationally. With a corpus of approximately 13,000 periodical issues split into nearly 200,000 pages, I am using Latent Dirichlet Allocation as implemented in Gensim to cluster the pages according to five different periodization schemes: no periodization (the whole corpus, spanning 70 years); periodization by decade (the corpus split by decade increments); cumulative periodization by decade (the corpus split by decade increments, but with each subsequent period added to the previous - i.e., 1844-1850, 1844-1860, 1844-1870, etc.); historical periodization (the corpus split according to "crisis" points in the denomination's history); cumulative historical periodization (the corpus split according to the historical periodization scheme above but with each subsequent period added to the previous).

Comparing these different schemes will enable me to explore whether and how periodization influences which discursive patterns I am able to surface computationally. To compare between the resulting models, I will evaluate on the following aspects: how well the documents are described by the topic labels assigned; the coherence of the topics, both internally and in relation to each other; and the visibility of change and development of topics over time.

My hypothesis is that the cumulative historical periodization will provide the richest picture of the shifts in the community's discourse. I anticipate that this will be visible through the percentage of documents labelled as relating to different topics, the appearance of new related topics over time, and different topic compositions at different points in time. However, I may conclude that the different periodization schemes provide little additional information. I propose that a negative conclusion is also important for the field and either result will provide productive information for developing computational methods that address the complexities that are at the heart of the humanities.

Digital Humanities Pedagogy in the University of Washington Information School MLIS Program

Helene C. Williams
helenew@uw.edu
University of Washington, United States of America

Digital Humanities Librarianship is a 3-credit elective open to University of Washington Masters of Library and Information Science students and a core elective in the Graduate Certificate in Textual and Digital Studies program. The course focuses on creating full contributors in the DH realm: a plethora (in academic terms, at least) of job postings for DH or Digital Scholarship librarians shows rapid growth in this area and a need for well-prepared individuals. No matter the physical location of DH centers—from libraries to academic departments to research centers—DH librarians are ideally suited for navigating the intellectual and geographic spaces of ideas, resources, and tools.

In addition to its unique hybrid format (synchronous residential and online), the course is also notable for providing a balanced approach to the theory vs. application tension typical of MLIS programs. Most DH courses in LIS departments focus on technologies, without concomitant attention to a foundational understanding of the varied research methods and resource usage patterns of humanities scholars. The DH Librarianship course aims to provide students with an understanding of how humanities scholars work, both traditionally and digitally, as well as familiarity with resources and tools used in digital humanities scholarship. The course also covers political and practical issues: what roles do librarians play in DH research, and what roles are situationally appropriate—tech guru, data cleaner, resource purchaser, equal collaborator? During the quarter, the course tackles questions of sustainability, accessibility, ethics, and equity in representation. Guest speakers include DH librarians (both with and sans MLIS), new DH faculty in various disciplines, and seasoned humanities researchers.

Assignments include disciplinary exploration, which allows students to explore resources and DH projects in philosophy, religion, fine and performing arts, languages and literatures. Student groups examine DH tools that range from timelines and mapping to text mining, information visualization, data cleaning, and network analysis, and create presentations from a shared corpus. In the final “DH consultation” assignment, students locate a project—in-process, abandoned, or “complete”—and propose options for library-based support, based on a disciplinary needs assessment. They also provide suggestions for strengthening the content, usefulness, or reach of the project, as well as a tools/usability assessment, which may include creating a prototype of an improved project.

The pedagogy reflects the multi-faceted disciplinary grounding and technological approach of the course content. My experience as an academic humanities librarian is bolstered by the research of many, including Melissa Terras, who discusses the need to identify core values and “hidden histories” of disciplines (2006), and Marcia Bates, who defines distinctions between disciplines such as the humanities and meta-disciplines like LIS (1999). In LIS we analyze the processes and domains of disciplines—in this case those involved in DH—and how those are represented, accessed, and given meaning across the corpora of recorded information. Mike Caulfield’s writing (2016) on multiple digital literacies also resonates with the pedagogies used, demonstrating the need for domain-grounded literacy to help students ascertain next steps and appropriate tools in their work with humanities scholars and projects.

The hybrid format of the class contributes to the collaborative pedagogy: local online and residential students attend the technology-enabled classroom in person, and others attend via the online Zoom classroom. Students can participate via audio or text, share screens, display presentations, or work in groups. Cameras in the classroom broadcast what is happening locally, and those attending online enable their webcams to be more fully present. In addition, several students each week attend via Kubi robots, which are iPads on movable stands that online users rotate to focus on different classroom activities. Guest speakers may attend in person, or they may present and engage with students via online options. These diverse modes of learning increase the students’ comfort with multiple technologies, which they are then more likely to use in their own research and teaching.

Learning outcomes include familiarity with the structure of knowledge in the humanities disciplines as well as the wide array of resources that provide reference and bibliographic support for research. Students are able to connect issues and concepts in DH to ongoing projects and scholarship, and they are able to articulate the ways in which library support fits into a changing paradigm of research in the humanities disciplines. In addition, students understand issues concerning equity, representation, and emotional labor in conjunction with digital humanities librarianship.

This poster will highlight the multiple teaching and learning techniques used in the course and student projects. It will also showcase the physical and virtual teaching and learning spaces.

Effective Identification of Citations in the Kanseki Repository

Christian Wittern
cwittern@gmail.com
Kyoto University, Japan

Introduction

The Kanseki Repository is a large repository of premodern Chinese texts. Currently it holds more than 9000 texts, covering all periods of Chinese history from early antiquity to the beginning of the 20th century. The repository is organized into 6 top-level categories and offers full-text search across all textual variants.

Since its opening to the public in March 2016, a frequent request from users was to be able to find texts related to a certain text, especially to investigate and evaluate textual dependencies. This poster reports on some experiments to find an effective way to respond to this requests.

What is needed to solve this problem is an efficient way to identify text passages that are derived from other, earlier texts (based on the assumption that the texts in question can in fact be reliably dated). Such passages will be called **citations** here, although the usage here is not limited to true citations, but also includes quotations from memory, paraphrases and allusions – cases where the reference does not follow the exact wording of the source. As an additional complication, we need to take into account the possibility that the received text differs from the text available to the author of the text that contains the reference.

Related work has examined plagiarism detection (Gipp and Meuschke, 2011 and Schultz, 1999), but the approach taken here makes direct use of some of the unique features of the repository and the index built for it and seems thus to be more efficient than general purpose algorithms. Admittedly, this has not been verified empirically and thus may be reasonably rejected as not relevant. However, the purpose of this presentation is not to compare algorithms and their efficiency when applied to the material here, but rather to collect some low-hanging fruit that became available due to the way the full-text index is constructed.

Identification of Citations

Index

Since a complete index has already been built for the full-text search, all experiments make use of this index (Mandoku 2016). The index is constructed by moving an n-gram window over the text and saving entries at appropriate locations. The resulting raw index is then read by a grep-like program to generate the display. The search display is designed to show the **keyword in context** (KWIC) so some characters are needed in front of the match character; these are appended after a comma character in the index entry. We built the index with a window between 10 and 25, since larger indexes considerable increase the required space and smaller builds will have too little information in the KWIC display. The index also contains information to identify the text, the location of the index excerpt and some information about the context of the match. Figure 1 shows a typical example of such an index for a 21-gram window.

Figure 1. Effective Identification of Citations in the Kanseki Repository

Algorithm

To find citations in the indexed files, a window of the same size as the index window is moved over the text passage under investigation. A search is initiated for a string of **n** characters, starting at the first index position. In the example in Figure 1 this would be starting at position 6, since there are 5 characters after the ","; these characters are preceding the indexed characters in the text and have therefore been moved to the back. A query expansion is used for this search, in order to catch character variants in this initial selection of index lines. A large value of **n** will increase the probability that citations are not found due to slight positional variations in the text, while a small value of **n**, such as 1, will select many lines that are not relevant and will thus increase the processing times. Experiments have shown that a value of 2 or 3 for **n** gives a good optimum for precision and recall. Positional values are also registered to better demarcate the citation boundaries.

The selected lines have to be post-processed to restore the original sequence as found in the text. The line will then be compared to the window of the text passage, with scores given for each match; high scores are taken to be a citation and are marked for further processing. The best results so far have been achieved for a cumulated score of n-gram matches for values of **n** from 1 to 3, but additional experiments are planned. Conclusive results will be reported in the poster presentation.

Additional expected results

With the method introduced here, it becomes feasible to investigate potential citations for whole texts. We plan to build a heat-map of a text with passages that have been cited coloured according to their frequency. This will enable new ways of exploring the intertextuality of texts and will provide new evidence for the history of ideas and flow of intellectual debt in the history of Chinese thought. For the presentation of the poster, we show a preliminary investigation of some key texts of Chinese philosophy as a proof of concept.

We also hope to identify a set of key phrases and look at their usages over time, and in different schools of thought, to see what kind of trends can be seen there.

Collecting the Name of a Historical Person from Related Historical Material

Taizo Yamada
t_yamada@hi.u-tokyo.ac.jp
The University of Tokyo, Japan

Satoshi Inoue
inoue@hi.u-tokyo.ac.jp
The University of Tokyo, Japan

This proposal describes a method of collecting and managing the name of a person from historical materials related to Japanese history from the 8th century until the 19th century.

There are several tasks related to personal name such as collecting, identifying, representing. For historians and researchers, the recording and management of a personal name is an integral (and unavoidable) task. In Japan, historical materials are held by both a public institute and a private house in which they are found. Because there are no catalogs listing all of the material, the research staff at our institute (the Historiographical Institute of the University of Tokyo) spend several weeks each year investigating and examining historical records kept in Japan and abroad. The staff has over 100 years' combined experience conducting these examinations, and their journeys have taken them all over Japan as well as to many different parts of the globe. Ho (2015) and Bol et al (2015) introduced a method of personal name management in the context of Chinese historical materials (like a "地方志 (difangzhi)") that used the China Biographical Database (CBCB) as a biographical dictionary. In Japanese history, there is no such exhaustive encyclopedia or dictionary for a name of a historical person.

A personal name appears in a variety of historical materials such as an old diary, an old document, a classical book, a family pedigree, a document related to appointment, and so on. The materials contain diverse name representations, such as a real name or an original name, a nickname, an epithet, a role name which indicates a person, and a Kao (which is a stylized signature or a mark), among others.

We constructed a repository which can store a collection containing both the names and the historical materials in which they appear. There are several different representations of a name in each material type. In order to represent and preserve these variations, the repository can store a variety of name data regardless of differences in data schema. In order to ensure efficient data-searching, we prepared common metadata that consist of an identifier, a personal name, a correspondence of the name, a related resource, a database where the name has been stored if such a database has already been constructed and the date on which the name appeared in the resource.

The name data can be expressed as RDF data and searched with SPARQL in the repository which provides an RDF store and a SPARQL endpoint. Furthermore, the repository can integrate the name data regardless of differences among personal name metadata schema, and provide the result of the integration. In addition, we will show an application for representing the outcomes of search results.

Interpreting Racial Identities and Resistance to Segregation in the Digital Sphere

Mishio Yamanaka
yamanaka@live.unc.edu
UNC Chapel Hill, United States of America

This poster demonstrates my digital history project, “The Fillmore Boys School in 1877: Racial Integration, Creoles of Color and the End of Reconstruction in New Orleans,” (http://fillmoreschool.web.unc.edu) which visualizes how, in 1877, Creoles of color, a group of francophone Catholics of interracial descent, responded to the city school board’s racial segregation plan. Through geo-spatial analysis and virtual representation of information of the Fillmore School student register, the project examines Creole families’ resistance to segregation and facilitates public understanding of ambiguous racial identities that become often invisible in the black and white racial dichotomy of United States history.

The Fillmore School served as a catalyst for Creoles’ ideal of racial equality and the center of their resistance to segregation. During Reconstruction, Creoles of color led the legal, political and grassroots campaign that ultimately resulted in the desegregation of approximately one-third of the public schools in New Orleans between 1871 and 1877. Fillmore was one of the integrated schools that many Creoles of color attended until the school board designated it as white-only in 1877. Its 1877 register contains 658 students’ individual information, including name, residential address, age, admission date, and parents’ name and their occupation. While the register does not list race, it includes notations of transfer to a “colored” school for 16 students. In addition, my digital research and mapping revealed that at least forty Creole students requested admission to the school as a sign of protest. This project thus demonstrates a complex process of segregation, resistance and racial identities among Creoles of color in New Orleans.

The project has undergone four processes: 1) transcription, 2) data collection, 3) mapping, and 4) website building. First, I digitized the entire 1877 Fillmore School student data. Second, I searched the 1870 and 1880 censuses and city directory information of the students by using ancestry.com. Next, I deployed ArcGIS and georeferenced the 1883 Robinson Atlas, the most comprehensive map of New Orleans for the era, and collected students’ latitude-longitude information. I used ArcGIS because it allowed me to publish the data as an interactive map while simultaneously conducting geospatial analysis. The project processed 566 student data entries to be published as an interactive map to the public. Finally, I built a website to contextualize the map.

The main part of my poster demonstrates the Arc-GIS map. It pays particular attention to the ways in which the map shows students’ residences with their variable racial information taken from the register, the 1870 and 1880 censuses and city directories. The map displays the complex reality of segregation in New Orleans. The censuses classified many Creole students as mulatto or white. However, the census racial information does not always correlate with that of the school register. The poster also focuses on how the map represents multimedia information about Creoles of color and shows their admission attempts as a tactic to resist racial resegregation. I will also discuss challenges I faced in mapping, including the lack of complete data.

The poster also introduces my project website that offers a virtual space for users to consider responses among ordinary Creoles of color confronting segregation and understand the complicated history of race and ethnicities in the United States. The website currently offers Creole family narratives to further contextualize the map. It also provides a short history of the Fillmore School and school racial policies in New Orleans.

Last, this poster discusses the future plan for the project. First, I will deploy social network analysis of the Creole parents and children at Fillmore and examine how their close social relationships contributed to resistance. Second, I plan to examine the Fillmore School history in the twentieth century by using oral interviews to reflect another desegregation attempt during the civil rights movement in the 1960s. Overall, this poster argues for digital ways to illuminate ambiguous identities and a wide range of struggles against racism in the late nineteenth century United States and discusses how digital humanities enrich historical research.

How can we test gamification and social learning in online writing environments? This poster will demonstrate an online writing environment, GWrit (Game of Writing), where students can comment on each other's writing and where they get rewards for task activity in a cooperative environment (gamification in this instance is not competitive). The application of game-based learning strategies to teaching writing shows promise, with one study reporting that their role-playing game improved the quality of student writing (Wang, Chen, Chang & Chan, 2016). GWrit has been developed by a cross-disciplinary team of academics and programmers at the University of Alberta over the past three years and has been used with over 1000 students.

This poster/demonstration brings together research on GWrit from the following perspectives: gamification, social-network influenced peer review, and the task completion structures. Our research will be summarized on the poster and we will demonstrate the environment during the poster session.

Gamification. Deterding (2011) defined gamification as the use of game elements and game design techniques in non-game contexts to engage people in solving problems. Gamified environments employ a number of mechanisms to encourage people to engage with them (Dicheva et al., 2015), and existing studies prove that gamified learning environments create deeper engagement of students (Barata, Gama, Jorge & Gonçalves, 2013; Fitz-Walter, Tjondronegoro & Wyeth, 2012). Our gamified environment has many "surface" (award trigger systems, competitive environments, badges, and ranks) as well as "deep" gamification components (task completion structures, social commenting support, public posting of draft documents).

When demonstrating GWrit we will first introduce the way the system was designed to support experimenting with commenting and gamification, and then show the gamification rule editing environment we developed. Our working hypothesis was that users want information about what they are doing and that gamification can be a playful way of representing that information back to the users so that they can make decisions and possibly be motivated differently.

Social-network influenced peer review. Social networking has also been shown to have a positive influence on students' academic learning (Tian, Yu, Vogel & Kwok, 2011; Tsuiping , 2016). Within GWrit we provided an environment where students have the opportunity to both read and then comment on each other's drafts, a technique that has been shown to improve writing (Schunn, Godley, & DeMartino 2016; Ion, Barrera-Corominas & Tomàs-Folch, 2016). Reading skill is directly linked to writing improvement, particularly if students are reading texts similar to the texts they are trying to produce (Hansen, 2013). GWrit allows students to post drafts of their documents for review and comment by other students, peer tutors, and graders. The writer of the draft can respond to each comment, and they are also likely to reciprocate by reading and commenting on the drafts of the students who gave them comments. Micro-networks of comments sprout up within the comments on these texts. Because students in the writing course version of GWrit have the option of working on one of three different assignments in each module, larger, informal networks of students who are working on the same assignment also coalesce. The writing course version of GWrit has four main three-week long modules with a choice of three assignments in each module; the social networks re-form at the end of each module. Our early assessments of students and commenting in the writing course confirm what others have reported: that peer feedback is as valuable as instructor feedback (Guasch, Espasa, Alvarez, Kirschner 2013).

Task completion structures. Third, the poster will deal with the role task completion structures play in motivating learning. GWrit incorporates three task completion structures to help students: the course completion fuel gauge, a task list, and assignment deadlines. All three of these task completion structures were used in WRS 102 in winter 2016 term and the first and the last structures were used in fall 2015 term. The data on the task structure from a course survey will be shown and discussed in the poster.

In our discussion of the research on the poster we will summarize interview data on why we think the various aspects of the system work, which areas we think need to be improved to work better, and how we intend to transform a curriculum-based tool (the course-based version of GWrit) into a free-standing, web-based site.

Pre-Conference Workshops and Tutorials

Construire sa bibliothèque numérique avec l'outil libre Omeka pour valoriser ses documents numérisés

Daniel Berthereau
daniel@berthereau.net
Indépendant, France et Canada

Description

Cet atelier d'initiation a pour objectif de permettre aux participants de construire leur première bibliothèque numérique libre et ouverte. Il vise à montrer que créer et utiliser une bibliothèque virtuelle est à la portée de tous, que l'on soit une grande institution, une bibliothèque, un service d'archives, un laboratoire ou une structure quelconque disposant de fonds documentaires ou archivistiques. C'est même possible d'en bas, par des bibliothécaires et par les chercheurs eux-mêmes, par exemple pour présenter les documents utilisés dans une monographie.

Il s'effectuera sur la base du logiciel libre Omeka S et sera divisé en quatre temps : réflexions autour de la conception de sa bibliothèque numérique, découverte et installation d'Omeka et de ses modules, création de documents et import de métadonnées et de fichiers, création d'une exposition virtuelle.

La bibliothèque numérique, un outil de base pour les humanités numériques

Une bibliothèque numérique est un site web qui permet de valoriser tous les documents numérisés dans des fichiers que l'on a dans ses armoires et ses tiroirs et qui dorment dans des disques durs, des CDs, dans des caves humides ou des greniers ouverts à tout vent, Les fichiers peuvent être issus de la numérisation de livres, de journaux, de cahiers, de registres, d'archives, de travaux étudiants, de cartes, de tableaux, de photographies, ou de toute autre image. Ce peut aussi être des fichiers audio ou vidéos ou d'autres formats issus de numérisations ou nativement numériques (pdf, images 3D de sculptures ou d'objets…).

De grandes bibliothèques numériques existent, comme Internet Archive, Hathi Trust, Europeana ou Gallica pour la Bibliothèque nationale de France, mais il en existe aussi des milliers d'autres pour des institutions plus petites ou pour des projets ou des fonds plus spécifiques. Historiquement, elles ont d'abord servi à publier des documents et à simplifier leur consultation sans contrainte de personnel et sans contrainte matérielle, notamment pour les documents fragiles ou précieux, avant que l'on rende compte que l'on pouvait faire beaucoup plus.

En effet, l'ouverture d'une bibliothèque numérique simplifie non seulement l'accès aux fonds, mais elle en démultiplie les possibles. Le simple fait qu'un fonds soit publié sur l'internet implique qu'il soit référencé automatiquement et qu'il soit donc mieux connu de la communauté des chercheurs et du public, qui pourront les découvrir, en prendre connaissance et les étudier facilement. Cela constitue une fondation pour la recherche dans les humanités numériques. Ensuite, comme dans une bibliothèque physique, dans un musée, dans des centres d'archives ou dans une galerie, les documents catalogués peuvent être valorisés par la création de collections et d'exposition temporaires ou permanentes. L'avantage de la dématérialisation est que les objets numériques peuvent appartenir à plusieurs collections et se trouver dans plusieurs salles ou sur plusieurs étagères, contrairement aux objets physiques. Quant aux expositions virtuelles, elles sont accessibles à tous et sans limitation, sans qu'il soit nécessaire de déplacer les documents ni que les chercheurs et les visiteurs ne se rendent physiquement sur place.

Au-delà de la publication et de la mise à disposition de documents, les bibliothèques numériques constituent aussi des outils de recherche. Les chercheurs les utilisent pour leurs propres recherches. En effet, la recherche est simplifiée en ce que la découverte, la comparaison et la confrontation des documents peut se faire en quelques clics. C'est d'autant plus vrai pour les documents textuels qui ont fait l'objet d'une océrisation ou d'une transcription, mais c'est aussi le cas pour tous les autres types de documents qui disposent de notices descriptives complètes et standardisées. Les chercheurs peuvent aussi les utiliser en aval pour publier leurs propres documents ou les documents libres de droits qu'ils ont utilisés, de la même manière qu'ils incluaient autrefois des photocopies dans leurs articles ou dans les annexes de monographies.

Il est aussi possible de faire appel à l'intelligence du public et à son temps libre dans une logique de science participative, par exemple pour identifier des informations sur des documents, pour compléter des notices, pour transcrire ou traduire des manuscrits ou simplement pour les étiqueter (ajouter des « *tags* ») dans une logique de folksonomie ou pour les commenter. C'est utile aussi bien pour les structures qui n'ont pas de moyens que pour celles qui n'ont pas de temps. Naturellement, cela implique un travail de communication qui dépasse la mise en place de l'outil.

Enfin, de par leur simple présence sur la toile, les documents et leurs métadonnées peuvent être échangés et réutilisés facilement par les autres sites et par les autres services de l'internet, dans la logique du web sémantique. On évoque ce dernier depuis longtemps, mais sa possibilité concrète et à la portée de tous est récente.

Le choix d'Omeka, un outil libre conçu pour le web sémantique

L'atelier d'initiation est conçu sur la base d'Omeka , un logiciel libre proposé par un centre de l'université George Mason en Virginie (États-Unis), le « Roy Rosenzweig Center for History and New Media », également créateur de Zotero, un logiciel de gestion bibliographique largement utilisé par les chercheurs. Omeka a été créé en 2007 et fête donc ses dix ans, avec une nouvelle version « Omeka S » spécialement dédiée au web sémantique.

La version actuelle, désormais renommée « Omeka Classic » et qui continue d'être maintenue, a pour objectif de reproduire le fonctionnement d'une bibliothèque et en reprend les concepts : création de notices de documents autour du Dublin Core ou de champs libres, création de types de documents, rassemblement des documents dans des collections, création d'expositions virtuelles, partage des données avec OAI-PMH, protocole d'échange largement utilisé dans les bibliothèques. Bien sûr, s'agissant d'un outil destiné à diffuser des documents souvent anciens, il n'y a pas de gestion des droits ni des prêts. Techniquement, Omeka est un CMS classique créé autour de php et mysql, basé sur la plateforme Zend, qui gère les utilisateurs, les vues, les urls, etc. Il dispose d'une api et il est extensible. Une dizaine de thèmes, avec un affichage réactif adapté à tous les écrans (« *responsive design* » / « *mobile first* »), et une centaine d'extensions (gestion des métadonnées, gestion des fichiers, visionneuses, contributions, diffusion) ont été développés par des universités, des agences web ou des prestataires, quasiment tous libres.

La nouvelle version « Omeka S », est une réécriture complète du logiciel et en reprend tous ces concepts, mais va au-delà en tirant pleinement parti des principes et des standards du web sémantique. Elle est en effet basée sur la spécification rdf, sur des ontologies (par défaut Dublin Core Terms, Bibliographic Ontology [bibo] et Friend of a Friend [foaf]) et sur le format json-ld. Elle est multisite (une seule installation d'Omeka permet de gérer plusieurs sites si besoin, avec des administrateurs indépendants). Son ergonomie a été repensée et les utilisateurs peuvent disposer de formulaires de saisie adaptés selon les types de documents. Elle est multilingue tant au niveau de l'interface qu'au niveau des métadonnées. Elle se concentre désormais sur la diffusion et des extensions permettant de synchroniser les documents issus d'archives institutionnelles telles que D-Space ou Fedora. Une dizaine d'extensions ont déjà été mises à niveau. Enfin, elle conserve la finalité d'Omeka Classic, celle d'être un outil simple ayant pour objectif effectif de mettre des concepts de la documentation numérique à disposition des non-spécialistes.

Finalité de l'atelier d'initiation

L'intérêt fondamental de cet atelier d'initiation pour la communauté des humanités numériques réside dans le concept même de bibliothèque numérique. Les bibliothèques et leur déclinaison numérique demeurent en effet un lieu essentiel pour les étudiants et les chercheurs, au cœur de la vie universitaire et de la recherche, quelle que soit la discipline. C'est aussi un lieu où les chercheurs peuvent présenter non seulement les résultats de leurs recherches, mais aussi les documents qu'ils ont utilisés pour celles-ci, lorsqu'ils sont libres de droits. Enfin, c'est un lieu où peuvent se retrouver et échanger les chercheurs et le grand public ou le public des amateurs éclairés, notamment dans le cadre de la recherche participative.

Présentateur

Daniel Berthereau

Daniel Berthereau, constructeur de bibliothèques numériques, a réalisé plusieurs bibliothèques virtuelles, depuis leur conception jusqu'à leur publication en passant par la préparation du cahier des charges, la normalisation des fichiers, la standardisation des métadonnées et leur import pour des bibliothèques et des centres de recherche de différentes disciplines. Il développe également des outils de conversion de métadonnées documentaires ainsi que des modules et des thèmes pour Omeka (cf. https://github.com/Daniel-KM).

Public visé et remarques techniques

Toute personne disposant de fonds numérisés et souhaitant les valoriser sur l'internet, en particulier les dépositaires de fonds, les bibliothécaires, les documentalistes chargés du système d'information, les curateurs, les archivistes et les chercheurs. Jusqu'à 20 personnes, avec leur ordinateur portable, une connexion internet et éventuellement quelques documents (fichiers et notices) pour expérimenter l'outil.

Programme

Cet atelier d'initiation de trois heures vise à présenter la création d'une bibliothèque numérique par sa mise en pratique réelle. Il s'agit d'une version synthétique d'une formation réalisée auprès de documentalistes et de chercheurs de l'Université Paris Ouest Nanterre (Labex « Des passés dans le présent »), auprès d'étudiants en master « Médiation culturelle et patrimoine numérique » de l'Université de Paris Vincennes-Saint-Denis et pour plusieurs bibliothécaires et conservateurs.

1. **Pourquoi construire une bibliothèque numérique avec Omeka ?**
    - Réflexions autour de la conception de sa bibliothèque numérique
    - Omeka et ses concurrents dans le cadre du web sémantique
    - Présentation d'Omeka (Omeka Classic et Omeka S) et de ses concepts

2. **Installation du logiciel**
    - Installation d'Omeka (ou utilisation d'instances préinstallées)
    - Présentation, choix et installation des modules
    - Choix et personnalisation du thème (interface graphique publique)

3. **Ajout des documents et des contenus dans le catalogue**
   - Création de son premier document numérique
   - Standardisation des métadonnées pour le web sémantique
   - Import de fichiers et de métadonnées en lot
4. **Valorisation des documents et des notices**
   - Modules de science participative
   - Modules d'exposition et d'échanges de données
   - Création d'une exposition virtuelle

Advancing Linked Open Data in the Humanities

Susan Brown

Carleton University, Canada

Brief Description

Since its inception, Linked Open Data (LOD) has been primarily about publishing and defining data standards. As the technologies have matured and the amount of data available for consumption has dramatically increased, the question of consumption and processing is now at the forefront.

- What will scholars do with a large universe of linked open data?
- What initiatives are needed? Which tools do we need most?
- If we consider access, discovery, and search to be solved (although that is debatable) what is missing to enable humanities scholars to benefit more from the turn to LOD?

We invite scholars working on LOD projects within the larger spectrum of the humanities to participate in a workshop that aims to understand the limits of current work in this area.

All participants will be asked to draft a 1-page position paper (no citations or bibliography needed) that envisions a new LOD tool.

These papers will be shared before the event. Participants will rank the position papers that in their view are most likely to provide a means of advancing LOD for the humanities if taken up at the workshop. The four ranked highest will be asked to give one of the pecha-kucha-style pitches elaborating their position to kick off the day.

After these brief introductory talks and brief responses, participants will divide into groups, jumping off from these ideas to envision and share ideas for new tools, initiatives, and methods of working with linked data.

The working session groups will aim at developing collaboratively a fuller elaboration of the proposals to be released to the wider community, and working if feasible towards a plan for the collaborative development of one or more of the ideas.

At the end, all participants will reconvene to share ideas and summarize the results of each group. The notes for each session will be tidied up into blog posts and will then be collated into a white paper or report, along with the preliminary papers, that highlights the various gaps and opportunities within the LOD landscape.

Workshop leaders

Susan Brown

Susan Brown is a Canada Research Chair in Collaborative Digital Scholarship and Professor of English at the University of Guelph, and Visiting Professor at the University of Alberta. She researches Victorian literature, women's writing, and digital humanities. All of these interests inform *Orlando: Women's Writing in the British Isles from the Beginnings to the Present*, an ongoing experiment in digital literary history published by Cambridge UP since 2006 that she co-directs. She directs the Canadian Writing Research Collaboratory, an online repository and research environment for literary studies in and about. Her current research touches on a range of topics in the digital humanities including interface design and usability, visualization and data mining, semantic technologies, and humanist-centered tool development. She is increasingly engaged with inquiry into how linked open data can serve humanities research. She also works on the impact of new technologies in the literature of the Victorian period. Brown is President of the Canadian Society for Digital Humanities/Société canadienne des humanités numériques.

Robert Warren

Rob Warren is a research associate with the Canadian Writing Research Collaboratory and Linked Modernisms projects at the University of Guelph. He also runs the Muninn Project, a large Linked Open Data project about the First World War. He is a professional engineer and adjunct professor in Mathematics and Statistics at Carleton University. Previously he was senior research fellow at the Big Data Institute in Halifax. His research interests lies in the design of ontologies and the application of artificial intelligence to digital humanities problems.

Abigel Lemak and Kim Martin

Abigel Lemak, a doctoral student at the University of Guelph, and Dr. Kim Martin, a Ridley Postdoctoral Fellow in Digital Humanities at the University of Guelph, will assist during the workshop.

Target Audience

Participants in DH2017 with a strong interest in linked data. We have invited a number of people who are very active in the field to join the workshop, and it looks like we will have input from the British Library, the Getty Institute, and the university library community, as well as DH researchers working from academic positions.

Let's Develop an Infrastructure for Historical Research Tools

Julia Luise Damerow
jdamerow@asu.edu
Arizona State University, United States of America

Dirk Wintergrün
dwinter@mpiwg-berlin.mpg.de
Max Planck Institute for the History of Science
Germany

Robert Casties
casties@mpiwg-berlin.mpg.de
Max Planck Institute for the History of Science
Germany

Scholars conducting historical research are provided with a growing range of digital humanities tools, supporting different phases of the research process: there is software for extracting text from documents (such as pdftotex, available on many Linux distributions or as part of Poppler), run OCR processes on images (for example Tesseract), tools for the creation, analysis, and visualization of datasets (for instance Nodegoat, Palladio, or Visualeyes), or software to work with annotations (for example Annotation Studio) or networks (such as Gephi or Cytoscape). Programming libraries are being developed to serve the needs of humanity scholars, like Spacy or Tethne. There are several repositories (such as HathiTrust or the Europeana) that provide access to sources and can easily be integrated into other services through APIs. Many tools, however, work well as self-contained units that scholars can use as singular parts of their research process, but cannot easily be combined into an integrated workflow by the researcher. Existing and new tools are developed using different languages and programming frameworks depending on requirements, skillset, and preference of the original developer, making reuse and integration harder for the developer seeking to combine several tools. Moreover, since most tools are developed independently of each other, many efforts are repeated by reimplementing functionality that is already provided by a different piece of software.

In this workshop, we would like to gather developers and programming-literate scholars to share their toolbuilding experiences and to present our first practical steps to create a system integrating multiple tools to work with historical documents from scan to analysis. The workshop is intended as a starting point for future exchange and cooperation for digital humanities developers.

In the summer of 2016, the Digital Innovation Group at Arizona State University (ASU) and the Max Planck Institute for the History of Science (MPIWG) started to combine their efforts in developing software for the history of science. One outcome of this collaboration is a research system that allows users to manage their documents, automatically runs OCR on uploaded files, provides an image viewer for uploaded and extracted images, and integrates document management with a multi-user Jupyter notebook server for writing analysis and visualization scripts. Rather than one big system, however, the research system is comprised of several integrated services developed independently of each other using different programming languages and frameworks.

For the Digital Humanities Conference 2017, we propose a full-day workshop with the goal to connect different tools and services to build a tool infrastructure for historical research.

The first half of the workshop will give tool developers a chance to present their software. Every presenter will be allowed 10 minutes for their presentation and 5 minutes for questions. ASU and MPIWG will present the different components of the developed research system. Specifically, we will present the following projects:

- Collaborative Jupyter Notebooks: a Jupyter Notebook server that allows sharing and publishing of notebooks based on Nextcloud and Dataverse.
- DocuManager: an environment for annotating, correcting and searching digital documents, in particular for OCR text in ALTO-XML and HOCR.
- Giles Ecosystem: an Apache Kafka-based service to extract images and texts from documents and run OCR procedures on them.
- Digilib: a Java-based IIIF-compliant image server and viewer.

The second half will be dedicated to discussing how different tools can be connected and integrated, and how we can build a community around those tools.

We envision the results of this workshop to be a concrete roadmap of how different tools will be integrated. We will define interfaces and API requirements, and if possible start development work during the workshop. Second, we will develop an organizational strategy for cooperation and collaboration among different projects. To aid organization, we will provide a Jira and Confluence project that participants can use during and after the workshop to organize collaboration.

We plan on organizing a follow-up meeting at the end of 2017 at Arizona State University to review progress since the initial workshop and plan next steps. If the collaboration is successful, we hope to establish regular meetings and expand the group to connect more tools and services.

Participants/Call

We will send out a call for participation in form of a short tool presentation for the first part of the workshop. We will ask presenters to focus on the technical perspective of their tool answering the following key questions:

- What is the general workflow of the tool?
- What is the core functionality of the tool?
- What input and output formats does the tool accept? Or what interfaces does it expose?
- What license model was chosen?
- What features are still missing and what are the next development goals?
- How is maintenance and development of the tool organized?

The deadline for the call is July 1st, 2017. We plan to accept 5-10 submission for our call, based on the usefulness of the tool and the potential for integration with other tools, which would all fit the first half of the workshop.

Audience

The target audience for this workshop are developers, historians with programming background, scholars with a technical background, and generally people involved in the development of tools to support historical research.

Confirmed Presenters

- Dirk Wintergrün (Max Planck Institute for the History of Science, Germany)
- Julia Damerow (Arizona State University, USA)
- Robert Casties (Max Planck Institute for the History of Science, Germany)
- Malte Vogl (Max Planck Institute for the History of Science, Germany)

High Performance Computing for Photogrammetry and OCR Made Easy

Quinn Dombrowski
quinnd@berkeley.edu
UC Berkeley, United States of America

Tassie Gniady
ctgniady@iu.edu

Megan Meredith-Lobay
megan.lobay@ubc.ca
University of British Columbia, Canada

John Simpson
john.simpson@computecanada.ca
University of Alberta, Canada

Computationally-intensive research methods have seen increasing adoption among digital humanities scholars, but for scholars outside R1 institutions with robust computing environments, techniques like photogrammetry or text recognition within images can easily monopolize desktop computers for days at a time. Even at institutions with a research computing program, systems are configured for scientific applications, and IT staff may be unaccustomed to working with humanities scholars, particularly those who are not already proficient at using the command line. National compute infrastructures in North America (Compute Canada and XSEDE) are a compelling alternative, providing no-cost compute allocations for researchers and offering support from technical staff interested in and familiar with humanities computing needs. This workshop will start by introducing participants to Compute Canada and XSEDE, cover how to obtain a compute allocation (including for researchers outside of the US and Canada), and proceed through two hands-on tutorials on research methods that benefit from the additional compute power provided by these infrastructures: 1) photogrammetry using PhotoScan and 2) using OCR via Tesseract to extract metadata from images.

Photogrammetry

Photogrammetry (generating 3D models from a series of partially-overlapping 2D images) is quickly gaining favor as an efficient way to develop models of everything from small artifacts that fit in a light box to large archaeological sites, using drone photography. Stitching photographs together, generating point clouds, and generating the dense mesh that underlies a final model are all computationally-intensive processes that can take up to tens of hours for a small object to weeks for a landscape to be stitched on a high-powered desktop. Using a high-performance compute cluster can reduce the computation time to about ten hours for human-sized statues and twenty-four hours for small landscapes. Generating a dense cloud, in particular, sees a significant performance when run on GPU nodes, which are increasingly common in institutional HPC clusters and available through Compute Canada and XSEDE.

One disadvantage of doing photogrammetry on an HPC cluster is that it requires use of the command line and Photoscan's Python API. Since it is not reasonable to expect that all, or even most, scholars who would benefit from photogrammetry are proficient with Python, UC Berkeley has developed a Jupyter notebook that walks through the steps of the photogrammetry process, with opportunities for users to configure the settings along the way. Jupyter notebooks embed documentation along with code, and can serve both as a resource tool for researchers who are learning Python, and as a stand-alone utility for those who want to simply run the code, rather than write it. Indiana University, on the other hand, has developed a workflow using a remote desktop interface so that all the GUI capabilities and workflows of PhotoScan are still available. A python script is still needed so that the user may avail herself of the compute nodes, but the rest of the workflow is very similar traditional PhotoScan usage. Finally, both methods offload the processing the HPC cluster, allowing users to continue to work on a computer that might normally be tied up by the processing demands of photogrammetry.

The workshop will give participants hands-on experience creating a 3D model using two different approaches: first, by accessing the Photoscan graphical user interface on a virtual desktop running on XSEDE's Jetstream cloud resource; and second, by using a Jupyter notebook running on an HPC cluster.

OCR

Optical Character Recognition (OCR) is a tool used for extracting text from images and is perhaps most well known as a core technology behind the creation of the Google Books and HathiTrust corpora. OCR continues to open historical texts for analysis at large scale, fuelling a significant portion of research work within the digital humanities to the point that it would be difficult to think of the "million books problem" existing without this technology. While there are many OCR tools available the most popular tool that is also free and open source is Tesseract.

This portion of the workshop will also make use of Jupyter Notebooks to provide templates for learning the development process and that can then be taken away to speed development of future code. We will feature two projects for participants to practice with. A "traditional" OCR task that will have workshop participants processing images from the London Times in a demonstration of the improvements in OCR over the past few years and a task focusing on processing historical photographs to find text that can be added to the associated metadata to improve the searchability of an index.

Target Audience

We anticipate that this workshop will appeal particularly to scholars who work with cultural heritage materials (a field where photogrammetry is an increasingly common method for generating digital surrogates), as well as those who work with archival photographs, and scholars with large corpora of photographs. It will also be relevant for scholars who already engage in computational analysis of primary sources, who wish to increase the efficiency of their analysis by leveraging high-performance compute environments. No previous experience with HPC environments is necessary. This workshop can accommodate 25 participants.

Instructors

Quinn Dombrowski

Quinn is the Humanities Domain Expert at Berkeley Research Computing. At UC Berkeley, Quinn works with humanities researchers and research computing staff at Research IT to bridge the gap between humanities research questions and campus-provided resources for computation and research data management. She was previously a member of the program team for the Mellon-funded cyberinfrastructure initiative Project Bamboo, has led the DiRT tool directory and served as the technical editor of DHCommons. Quinn has an MLIS from the University of Illinois, and a BA and MA in Slavic linguistics from the University of Chicago.

Tassie Gniady

Tassie manages the Cyberinfrastructure for Digital Humanities group at Indiana University. She has a PhD in Early Modern English Literature from the University of California-Santa Barbara where she began her digital humanities journey in 2002 under the wing of Patricia Fumerton. She coded the first version of the NEH-funded English Broadside Ballad Archive, making many mistakes and learning much along the way. She now has an MIS from Indiana University, teaches a digital humanities course in the Department of Information and Library Science at IU, and holds regular workshops on text analysis with R and photogrammetry.

Megan Meredith-Lobay

Megan Meredith-Lobay is the digital humanities and social sciences analyst, as well as the Vice President, for Advanced Research Computing at the University of Briitsh Columbia. She holds a PhD from the University of Cambridge in medieval archaeology where she used a variety of computing resources to investigate ritual landscapes in early medieval Scotland Scotland. Megan has worked at the University of Alberta where she supported research computing for the Faculty of Arts, and at the University of Oxford where she was the programme coordinator for Digital Social Research, an Economic and Social Research Council project to promote advanced ICT in Social Science research.

John Simpson

John Simpson joined Compute Canada in January 2015 as a Digital Humanities Specialist and bringing a diverse background in Philosophy and Computing. Prior to Compute Canada, he was involved in a research-intensive postdoctoral fellowship focusing on developing semantic web expertise and prototyping tools capable of assisting academics in consuming and curating the new data made available by digital environments. He has a PhD in Philosophy from the University of Alberta, and an MA in Philosophy and BA in Philosophy & Economics from the University of Waterloo. In addition to his role at WestGrid, John is also a Member-at-Large of the Canadian Society for Digital Humanities (CSDH-SCHN), a Programming Instructor with the Digital Humanities Summer Institute (DHSI), and the national coordinator for Software

Séance d'initiation à la vidéo adaptée à la recherche SHS

Christian Dury
christian.dury@ish-lyon.cnrs.fr
Institut des Sciences de l'Homme, France

Cadrage de la problématique

L'image fixe ou animée est un outil de plus en plus important dans les recherches en sciences humaines et sociales. Son usage vient questionner le chercheur dans l'évolution du processus de recherche : recueil des données, analyse et restitution des résultats. Partant de ce constat, cette séance d'initiation se veut un espace de réflexion sur la place de l'image animée dans une recherche. Comment l'intégrer dans le travail scientifique ? Que peut-elle apporter au chercheur ? Quelles modifications relationnelles peut-elle entraîner dans le rapport au terrain ?

Dans une perspective de construction des savoirs, une vidéo permet de rendre compte de façon explicite des résultats de recherche en prenant plusieurs formes. Par exemple, elle peut être utilisée brute dans le cadre de recherche expérimentale, pour faire réagir à un phénomène par exemple. Elle peut se construire sous forme de documentaire pour expliciter, communiquer ou valoriser une théorie.

Qu'il s'agisse d'écrire un documentaire, de filmer une manifestation, d'enregistrer un entretien ou de capter une expérience, l'objectif de mise en image amène les chercheurs à s'interroger autour de la question : *« qu'est-ce que filmer en Sciences Humaines et Sociales ? »*.

Objectifs

Rien ne vaut la pratique pour se familiariser avec la technique audiovisuelle. Cette séance permet de découvrir les moyens d'analyser/restituer/communiquer/valoriser avec l'image animée autour de thématiques de recherche en SHS.

Cette séance d'initiation a pour objectif d'acquérir une autonomie avec le matériel sur des tournages légers et aborder l'ensemble des phases de réalisation (de l'écriture à la diffusion).

Lors de cette séance, les principales règles de captation vidéo seront abordées sous forme d'exercices pratiques autour de l'entretien filmée, par exemple. Ces images serviront de base pour aborder le montage numérique de données vidéos sur un logiciel de traitement des images et du son.

Prérequis

- Avoir des projets où l'image animée est mobilisée dans ses problématiques scientifiques.
- Avoir des envies d'utilisation de la vidéo dans ses recherches.

L'ISH organise ce genre de module d'initiation depuis juin 2016.

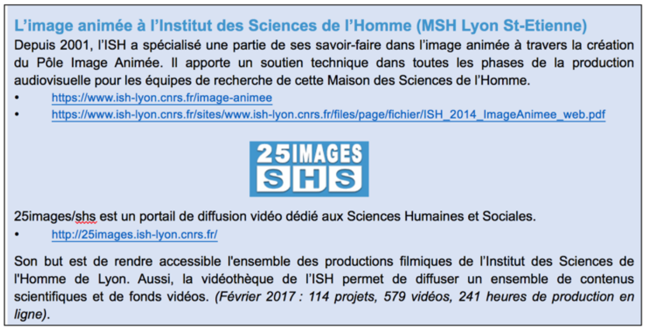
Aussi, en lien avec l'Ecole Doctorale « Sciences Sociales » de l'Université de Lyon 2, l'ISH co-organise les ateliers « Image dans les recherches en sciences humaines et sociales » (22h en 2017).

Programme de la journée

La matinée sera consacrée aux techniques de prise de vue adaptées à la recherche avec des exercices pratiques permettant d'approcher différents dispositifs filmiques.

L'après-midi s'articulera autour de la post-production en travaillant sur les prises de vue du matin sur un logiciel de montage.

La journée abordera enfin les questions de diffusion notamment avec l'expérience de la plateforme de diffusion vidéo de l'Institut des Sciences de l'Homme : 25images/shs .



L'image animée à l'Institut des Sciences de l'Homme (MSH Lyon St-Etienne)

Depuis 2001, l'ISH a spécialisé une partie de ses savoir-faire dans l'image animée à travers la création du Pôle Image Animée. Il apporte un soutien technique dans toutes les phases de la production audiovisuelle pour les équipes de recherche de cette Maison des Sciences de l'Homme.

- https://www.ish-lyon.cnrs.fr/image-animee
- https://www.ish-lyon.cnrs.fr/sites/www.ish-lyon.cnrs.fr/files/page/fichier/ISH_2014_ImageAnimee_web.pdf

25images/shs est un portail de diffusion vidéo dédié aux Sciences Humaines et Sociales.

- http://25images.ish-lyon.cnrs.fr/

Son but est de rendre accessible l'ensemble des productions filmiques de l'Institut des Sciences de l'Homme de Lyon. Aussi, la vidéothèque de l'ISH permet de diffuser un ensemble de contenus scientifiques et de fonds vidéos. *(Février 2017 : 114 projets, 579 vidéos, 241 heures de production en ligne).*

The Design of Historical Data Projects: The Comédie Française Registers Project and the Laboratoire Paris XVIII. A hands-on workshop and conversation about creating datasets for historians and developers.

Abstract

The Comédie Française Registers Project (or “CFRP”) and the Laboratoire Paris XVIII *(*or “LP18”) both aim at understanding social and cultural phenomena in Paris in the 18th century by collecting and utilizing data from relevant historical documents, and creating and supporting communities of practice and scholarship around those data using web technologies.

Through an overview of the Comédie Française Registers Project (CFRP), and hands-on engagement with the dataset compiled by that project, participants will gain a shared context for discussion of historical data projects.

On that basis, we will introduce the “Laboratoire Paris XVIII” (LP18), which aims to create a collaborative workspace to support the compilation of datasets about life in 18th-century Paris from primary source materials, and visualizations of those data in time and space.

Participants in the workshop will then engage in a discussion of how the “LP18” project and platform should be designed, in light of the successes of the CFRP project, to maximize its accessibility and utility.

This workshop is aimed at researchers and developers, and presented in French and English.

Description

Part 1: Introduction: The Comédie Française Registers Project

We’ll open with a presentation of the Comédie Française Registers Project by two of the project’s principal investigators. From the CFRP website:

> *From 1680 until 1791, only one theater troupe in Paris was allowed to perform the plays of Molière, Corneille, Racine, Voltaire, Beaumarchais, and every other French-language playwright. This troupe, the Comédie-Française, played the works of these authors over 34,000 times in this period. Remarkably, the troupe kept detailed records of their box office receipts for every single one of those performances. These daily receipt registers, still housed today in the troupe’s archives in the heart of Paris, are now available online via the Comédie-Française Registers Project.*

The CFRP has created web-based tools to collect and manage ticket receipt data, and to search, analyze and visualize those data to support research and collaboration.

We will demonstrate some examples of how scholars and developers have integrated the CFRP data into research and teaching practice, extended it for specific use cases, connected with other datasets, and contributed their work back to a growing community of practitioners.

- Project overview, history, and results to date: Dr. Jeff Ravel, Professor and Head of History at MIT
- Tools, visualizations, and future work planned: Dr. Sara Harvey, Professor of French Literature at University of Victoria

Part 2: Hands on with CFRP data

We will then move to structured hands-on work with the CFRP dataset, in which participants may try out the various modalities of access to the data, come to grips with the data themselves, ask and answer research questions, and envision new applications.

After an orientation to the CFRP website, tools and applications, participants will select from a several structured,practical activities to be done individually or in pairs. Members of both the CFRP and the LP18 project teams will participate and answer questions.

Part 3: Le Laboratoire Paris XVIII

Next, we will introduce the LP18 project, with an overview of the project's goals, context and methods. From the project description:
Labo Paris XVIII, or LP18, and the software it envisions, will be a platform for assembling, sharing and using datasets relevant to life in Paris in the 18th century. These datasets will provide lenses through which to view the "information networks" of the time, and through them, the life of the city and its citizens. By assembling a diversity of archival material, most of it unpublished, LP18 aims to make it possible to search a unique corpus of sources, some printed, others handwritten, and to visualize them on an historical map of the city. Members of the project team will comment on key aspects of the project.

- Historical context and project overview: Dr. Pascal Bastien
- Geospatial considerations: Dr. Julien Puget
- Environmental Scan: Dr. Benjamin Deruelle

Part 4: Discussion

Following the introduction of the LP18 project, will be a discussion of the fields of research and technology in which these two projects are situated, with the aim of informing how LP18 can be informed by those other efforts, and designed for accessibility and utility.
Presenters will frame key questions to introduce the conversation. Topics may include:

- Practical considerations in collaborative data projects
- Document digitization, ingestion and data extraction
- Intellectual property considerations in historical data projects
- Example projects, datasets, tools and software
- Database and API design
- Using open source software and open standards, production open data
- Communicating across disciplines, languages and time zones

Conclusion

Time will be reserved at the end of the workshop for feedback, thoughts and questions.

Digital Scholarship and Privacy-sensitive Collections

Unmil Karadkar
unmil@ischool.utexas.edu
University of Texas at Austin, United States of America

King Davis
king.davis@ischool.utexas.edu
University of Texas at Austin, United States of America

Introduction

Humanities scholars have historically used archives that include restricted or privacy-sensitive collections in order to conduct their investigations about sensitive topics. The recent developments in digitization and dissemination technologies present the possibility of making archival collections broadly available. Furthermore, collections of new, born-digital documents will be readily available to support and enhance scholarship. However, such access has also exacerbated threats to the privacy of individuals named in these records. Examples of such privacy-sensitive records include mental health institutional records, prison records, records of the Truth and Reconciliation Commission, Nazi archives, and the Guatemalan police archives. In the physical world, access to these records is protected by distance, physical access, and a variety of national and local statutes. The legal framework for digital records is substantially behind that for physical records. Furthermore, the online availability of such records has a potential to stigmatize or embarrass the families or descendants of those named in the records when they bear no responsibility for the acts or afflictions of the named individuals, raising ethical issues in providing broad, open access to these records.

The organizers are studying the legal, conceptual, and practical issues in harnessing such privacy-sensitive collections in the service of scholarship—for example in history (of medicine and mental health), law, and social services. Our research is funded by the Andrew W. Mellon Foundation (grant number: 11500653) under the scholarly communications program.

This workshop will invite broad participation from scholars and practitioners who work with or are interested in issues surrounding humanities scholarship supported or enhanced by digital, privacy-sensitive collections. A non-exhaustive list of topics of interest include:

- Digitization, curation, and preservation of privacy-sensitive collections
- Theoretical and metadata models
- Policies, workflows, and protections for accessing materials

- Issues in using cloud services for privacy-sensitive materials storage and scholarship
- Scholarly information behavior and needs
- Models for balancing privacy of named entities versus access to specific demographics
- Mechanisms and models for data retrieval from handwritten documents
- Privacy-aware digital repository architectures
- Privacy-aware crowdsourcing and transcription methods
- Privacy issues in designing user interfaces and data visualizations
- Privacy mitigation in data analytics and presentation

Workshop organizers

Unmil P. Karadkar

Unmil P. Karadkar is an assistant professor in the School of Information at The University of Texas at Austin. He situates his work at the intersection of digital libraries, human-computer interaction, and visualization. He studies data practices of researchers with an eye toward identifying unmet information needs. Based on an understanding of these needs, he designs software to support their evolving practices and evaluates the impact of this software on their work. His research contributes to areas such as the design of digital collection interfaces and digital humanities. His research has been funded by the National Science Foundation, Texas General Land Office, USAA, and most recently, the Andrew W. Mellon Foundation.

King Davis

King Davis is a research professor in the School of Information at The University of Texas at Austin and has made outstanding contributions in the field of Health and Mental Health over the last three decades. Dr. Davis held the Robert Lee Sutherland Chair in Mental Health and Social Policy at the University of Texas at Austin, School of Social Work. From 2003-2008, Dr. King also served as the Executive Director of the Hogg Foundation, which awards grants and manages programs to improve mental health research and services in Texas. Prior to his work in Texas, Dr. Davis served as the Commissioner of the Department of Mental Health, Mental Retardation and Substance Abuse Services for the Commonwealth of Virginia by Virginia Governor L. Douglas Wilder. He also has served as the John Galt Chair in Public Mental Health at the University of Virginia's Department of Psychiatry. Dr. Davis has held academic appointments at Washington University in St. Louis, Virginia Commonwealth University, Eastern Virginia Medical School and Norfolk State University. Dr.

Davis received his PhD from Brandeis University, Florence Heller School for Social Policy and Management, and his MSW from California State University Fresno, School of Social Work. He has written and published numerous articles and reports on mental health, fund raising, managed health care and social justice. His book, The Color of Social Policy, was published in 2004.

Target audience and expected number of participants

This is our first workshop on this topic and we are unsure what the interest will be. In this light, we have tried to make the topic as broad as possible, while retaining the core characteristics and constraints that we have found in our work. Our poster at DH 2014 was well-received and several conference attendees expressed an interest as well as challenges in working with collections similar to ours. The collections they described were geographically and topically diverse. With this experience, we anticipate receiving 10 to 20 submissions and accepting 8 to 10 for presentation at the workshop. We are unable to gauge the level of interest in the DH community in attending the workshop without presenting.

Length and format

We propose to hold our workshop for one day. This time frame will allow for adequate exploration of the various aspects of the workshop topics as well as domains via presentations, as well as in-depth discussion. We are open to conducting the workshop on a single day or as two half days.

The workshop will be held in a seminar style, with several short and long presentations. Individuals may participate in the workshop without presenting. The organizers will include an open discussion time to engage the audience and, especially, to tease out aspects of scholarship with privacy-sensitive digital collections that the presentations do not cover.

Program Committee

We will assemble a diverse program committee that includes scholars and practitioners with a diverse expertise. Potential invitees include:

- Tom Cramer, Assistant University Librarian-Library Technology, Stanford University
- Karen Estlund, Associate Dean for Technology and Digital Strategies, Penn State University Libraries
- Donald Fyson, Professor-History, Universite Laval
- Pat Galloway, Professor-Information Studies, The University of Texas at Austin Gary Geisler, UX Designer, Stanford University Libraries
- Geoffrey Rockwell, Professor-Philoshophy and Humanities Computing, University of Alberta Martin Summers, Associate Professor-History, Boston College

We welcome input from the DH 2017 program committee for additional suggestions for program committee members.

CATMA 5.0 Tutorial

What is CATMA?

This hands-on tutorial introduces humanists to CATMA (Computer Aided Text Markup and Analysis), a tool developed at the University of Hamburg and currently used by over 60 research projects worldwide. CATMA offers a unique combination of three main features found in no other text analysis tool:

CATMA supports **collaborative annotation and analysis** – a text or text corpus can be investigated individually, but also jointly by a group of students or researchers.

CATMA supports **explorative, non-deterministic practices of text annotation** – a discursive, debate-oriented approach to text annotation based on the research practices of hermeneutic disciplines is the underlying conceptual model.

CATMA integrates **text annotation and text analysis** in a web-based working environment – which makes it possible to combine the identification of textual phenomena with their investigation in a seamless, iterative fashion.

What sets CATMA apart from other digital annotation methods is its 'undogmatic' approach: the system does neither prescribe defined annotation schemata or rules, nor does it force the user to apply rigid yes/no, right/wrong taxonomies to texts (even though it allows for more prescriptive schemata as well). Rather, CATMA's logic invites users to explore the richness and multi-facettedness of textual phenomena according to their needs: Users can create, expand, and continuously modify their own individual tagsets – so if a text passage invites more than one interpretation, nothing in the system prevents assigning multiple, or even contradictory annotations. Despite all this flexibility, CATMA does not produce idiosyncratic annotations: All markup data can be exported in TEI/XML-format and reused in other contexts.

Since CATMA is a highly intuitive tool, it is also suitable for humanists with little technical knowledge: the GUI allows for a quick kick-off, and CATMA's query builder (a step-by-step dialogue-based widget) helps users retrieve complex information from texts without having to learn a query language. Another plus on the easy-to-use side is the fact that CATMA's automated distant-reading functions are continuously enhanced and extended – the current version 5.0 already features a number of automated annotation routines, among others the identification of basic narrative features in texts.

The aim of the tutorial

In our half-day tutorial, we will introduce the core annotation and analysis functionalities of CATMA and show how they can be combined with the annotations provided automatically. Participants will be taken in a step-by-step, hands-on approach through the full cycle of a CATMA-based text investigation:

- From text upload to initial textinvestigations,
- then to annotation and specification of annotation categories,
- from there to combined text queries that consult the source text and its annotations in combination,

and finally to the visual output of queryresults.

In a later phase of the tutorial, participants will have the opportunity of testing the tool with regards to their own research interests: They can annotate their own texts or annotate collaboratively a text we will provide. We would also like to engage participants in a critique of CATMA's design and components as well as a general discussion about requirements for text analysis tools in their fields of interest.

The primary users of CATMA are literary scholars, as well as graduate and undergraduate students of Literary Studies. Nevertheless, this tutorial is likely to be of interest also to:

humanities scholars of ALL fields concerned with text analysis (with and without experience in digital text analysis),

software developers in the humanities interested in non-deterministic text analysis and automated annotation.

Participants need no prior knowledge of digital text annotation and can work with their own laptop computers and their own digital texts. CATMA runs on Laptop or PC (Windows, Unix or MacOS) with a current web browser (MS Explorer or Edge; Firefox, Chrome, Safari) with a mouse or touchpad. Touchscreen navigation is not yet supported (but in the pipeline!). The room in which the workshop takes place should accommodate 25–30 people and provide WLAN and a projector.

Tutorial Instructors

All tutorial instructors come from the developing team of the CATMA project and/or the forTEXT project that is building a platform starting from CATMA. We have been presenting and teaching CATMA on various national and international occasions in the last years.

Evelyn Gius

Evelyn is working in the field of Digital Humanities as a researcher and has been involved in the creation of CATMA from the very beginning. Her research focus is on manual and automated text analysis. For her PhD project in Literary Studies she has explored with CATMA the benefits of applying narratological categories from literary studies to the analysis of narrations of labor conflicts.

Jan Horstmann

Jan uses CATMA as a tool for textual analysis in literature studies and narratology. Currently he is investigating works of Goethe with a combination of distant and digital close reading methods. His focus is to improve the usability of digital tools for people with little or no prior knowledge of computing or programming, i.e. researchers from classical literature studies.

Janina Jacke

Janina Jacke has worked in the heureCLÉA project (2013–2016) that was aimed at developing automated annotation routines for CATMA. Since her research focuses on narratology and theory of interpretation, her main interest in the DH-context lies in working out the theoretical prerequisites for automated literary annotation.

Jan Christoph Meister

Chris is Professor of German literature with a main research focus in the Digital Humanities. As original inventor of CATMA, he has led several projects concerned with the annotation and visualization of literary data and the development and enhancement of DH-tools.

Marco Petris

Marco is a computer scientist with a strong affinity for the humanities and has been engaged in the creation of CATMA from the very beginning. As a research developer he is involved in all aspects of the design and implementation of tools for the Digital Humanities.

Hands on Text Analytics with Orange

Orange for Text Analytics

In recent years, the digital humanities community has been introduced to many powerful tools for text analysis, but few of these tools combine powerful data mining and machine learning algorithms within a simple and capable user interface. For flexible and creative analysis, researchers need a tool that focuses on intuition, visualizations and interactivity.

This workshop will introduce participants to Orange, a visual programming environment for data mining, suitable for both beginners and experts. Particular emphasis will be placed on its Text add-on, which offers components for text mining, visualization and deep- learning-based embedding.

This is a hands-on workshop, where the participants will actively construct analytical workflows and go through case studies with the help of the instructors. They will learn how to manage textual data, preprocess it, use machine learning, data projection and visualisation techniques to expose hidden patterns and evaluate the resulting models. At the end of the workshop, the participants will know how to use visual programming to seamlessly construct powerful data analysis workflows, which can be applied to a wide range of challenges in digital humanities.

Structure of the Workshop

Part 1: Visual programming, workflows, data input and preprocessing

First, we will show the basics of Orange: how to load the data, inspect and visualize it. Participants will be introduced to several options for data import, from standard Corpus to Twitter, Guardian and Text Import. Once the corpus is loaded, we will preprocess it and display the result in a word cloud. A particular emphasis will be on the use of custom preprocessing techniques and how to successfully apply them to the corpus. The results of each technique will be observed in an interactive word cloud and concordances.

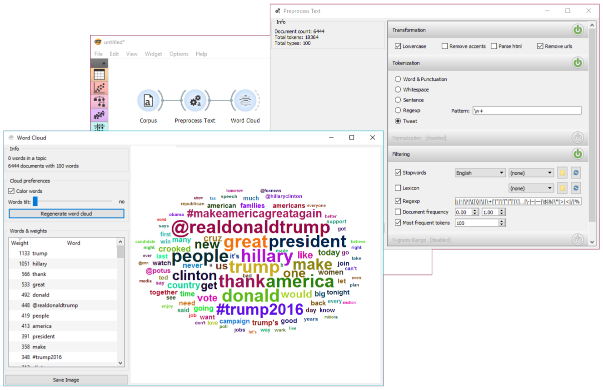

Figure 1: Preprocessing results displayed in a word cloud

Part 2: Machine learning and deep-learning-based embedding for predictive analysis

Next, we will use Twitter data to construct an author prediction pipeline and test some classifiers. We will fetch author Timelines from Twitter and observe the retrieved corpus. This time we will introduce a pre-trained tweet tokenizer and pass the preprocessed corpus through a bag of words. We will discuss bag of words parameters and how to best prepare the data for further analysis. The results of using different parameters will be observed in a data table to understand the underlying data structures. For comparison, we will use deep-learning-based embedding to derive vector representation of tweets and in this way enable machine learning.

We will explain how we can use machine learning in text mining and introduce a number of techniques for predictive analysis. We will use cross-validation to test the constructed bag of words models and compare classification scores for each algorithm. We will discuss the quality of constructed models and what scores are usually the best for observing model quality. Additionally, we will inspect misclassified tweets in a confusion matrix and even further in Corpus Viewer, to leverage the possibilities of a close(r) reading.

Part 3: Data clustering, sentiment analysis, image and geo analytics

In the third part, we will work on geomapping and image analytics. We will transform textual and visual data into feature vectors and plot these data onto a world map to discover interesting relations.

We will discuss how to acquire geolocated data from Twitter and why this is useful. Next, we will use geotagged Twitter data and apply a pre-trained sentiment analysis model to acquire sentiment orientation. We will map the sentiment-tagged tweets and explore how to use sentiment together with geomapping.

Finally, the participants will be introduced to image analytics for humanities research. We will explain why and how to transform raw images into multidimensional vectors and how to work with the new data. We will cluster Instagram images into groups and explore how to map image-containing tweets on a world map. Do images correspond to geolocation? We will see.

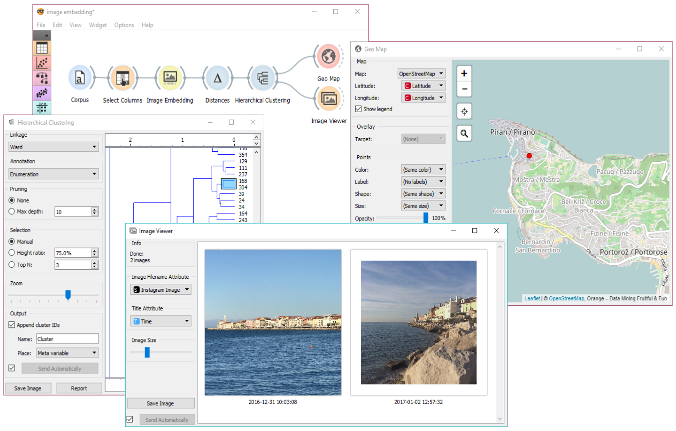

Figure 2: Images from social media are embedded with ImageNet embedding, clustered with Hierarchical Clustering and displayed on a map by their geolocation.

From Text to Networks: Combining Entity and Segment Annotations in the Analysis of Large Text Corpora

Nils Reiter
nils.reiter@ims.uni-stuttgart.de
University of Stuttgart, Germany

Maximilian Overbeck
maximilian.overbeck@sowi.uni-stuttgart.de
University of Stuttgart, Germany

Sandra Murr
sandra.murr@ilw.uni-stuttgart.de
University of Stuttgart, Germany

Introduction

In this half-day tutorial we will offer a full-fledged, implemented and tested workflow that has been developed in the interdisciplinary *Center for Reflected Text Analytics* (CRETA, a research center connecting both scholars from Humanities/Social Sciences and Computational Linguistics at the University of Stuttgart). Our focus is the valid and reliable identification of various kinds of entities and segments from raw, un-annotated texts and the extraction of specific relational information via network visualizations. Given the recent interest in networks for data representation and visualization (e.g., Gephi-tutorial at DH 2016), we argue that the following three-step-workflow is applicable to many research questions in the Social Sciences and Humanities:

1. Detection of entity references in texts of different genres (*e.g. references to chancellor Merkel in parliamentary debates)*,
2. Segmentation of the texts guided by research questions (*e.g. parts of a parliamentary speech dealing with the Greek financial crisis*), and
3. Creation of networks of entities that co-occur within a segment *(e.g. references to national or international organizations in a parliamentary debate dealing with the issue of wars and military interventions).*

This workflow is one example of modularizing complex research questions into concrete steps and can moreover be combined with computational methods for the semi-automatic analysis of very large text corpora. The concepts of "entity" and "segment" are sufficiently generic to allow the same set of tools to be employed in different research questions originating from different fields of research. The tutorial is therefore not aimed at a specific Humanities or Social Sciences discipline and instead open to all researchers interested in the analysis of entity relations in large amounts of textual data.

In our tutorial we will make use of the web-based annotation tool CRETAnno developed to support semi-automatic annotation. CRETAnno provides tools for annotation and continuous assessment of *inter-annotator agreement*, thereby facilitating the production of reliable and valid data. Our tool facilitates the annotation of large text corpora: After some training instances are annotated, a machine learning model can be trained to predict new instances on additional texts, which can then be corrected and used as additional training material. This way, large texts can be annotated (relatively) quickly, given systematic manual annotation and clear annotation guidelines. This 3-step approach is currently investigated within the *Center for Reflected Text Analytics* (CRETA) on four distinct text corpora, connected to diverse research questions in different disciplines. Although establishing broadly applicable workflows has its merits (Kuhn & Reiter, 2015), we believe it is important to be able to "parameterise" them to take into account the specificities of a concrete research question. Research questions should govern the definition of entities, segments and weighting criteria in the network. In the tutorial, participants will be free to bring in (and work on) their own research questions (within the time limits of the tutorial).

Entity Reference Detection

Every concept of interest within a real or fictional world can be considered as an entity. Words in a text refer to th ese entities and are therefore called *entity references*. We have established annotation guidelines that distinguish six entity classes, oriented at the research questions within CRETA: *Person*, *Location*, *Organization*, *Work* (e.g., a piece of art), *Event* and *Abstract Concept* (e.g., art).

While these entities are semantically diverse, their linguistic representation in texts is similar: References are either proper nouns (*Hillary Clinton*/*EU*), pronouns (*she*/*it*) or appellative noun phrases (*an American politician* / *the international organisation*).Most of the entity references consist of a few words, but we generally opt for annotating full noun phrases (e.g., *the British people after having voted for the Brexit*). In order to be able to link entities semi-automatically, we focus on appellative noun phrases and proper nouns, and ignore pronouns (see below).

The notion of "entity reference" we are aiming for differs from what is known in **Named Entity Recognition** (NER) and **Coreference Resolution** (CR). In NER, only proper nouns are detected, while CR also aims to resolve pronouns. Our notion of entity reference detection is aiming for the middle ground. By excluding pronouns, we also exclude the most ambiguous words, whose co-reference properties typically can only be judged in context of their appearance. Appellative NPs contain enough information such that we can establish their identity with proper nouns with relatively simple lists and rules.

Text Segmentation

Researchers from Humanities or Social Sciences generally want to inquire either the interaction between entities (within certain contexts) or between entities and the contexts themselves. Text segmentation is our way of operationalising this context. The notion of segment -- again -- is a generic one, to be adapted to specific research questions and/or theoretical assumptions made within a discipline or research area. Different kinds of segmentation are distinguishable: A **segmentation according to structural units** like chapters (narratives), speeches (minutes of parliamentary debates) or acts (dramatic texts) relies on the proper detection of such segments in the original texts and is therefore highly intertwined with the concrete text format at hand. Although machine learning models can be trained to perform such tasks, they likely do not generalize well to new texts. Even in TEI-encoded dramatic texts (which are strongly structured), there are a lot of options how to encode acts. We therefore aim for making it easy for researchers from Humanities and Social Sciences to detect such segments using metadata (e.g. dates of publication of a newspaper article or a parliamentary debate), text-specific regular expressions and/or rules.

A second kind of segmentation is **segmentation according to content** criteria. Depending on text genre and research question, this can mean segmentation by topic, narrative level, plot, time, location etc. One possible application is the segmentation of newspaper content according to various topics (Kantner & Overbeck 2017, forthcoming).

Structurally, segment annotations differ from entity reference annotations by being longer and thus sparser within a text. This has consequences for the semi-automatic support, because annotating a sufficient number of training instances requires more text to be read (and analysed with respect to its segmentation) and thus takes more time. CRETAnno therefore supports a number of unsupervised segmentation algorithms that can be used directly. In addition, researchers can specify text patterns using regular expressions and simple rules and thus focus the segmentation on the specific research question they have.

Entities + Segments = Networks

Given entity reference and segment annotations, it is only a small step to extract network-like data based on co-occurrence. As the entity reference annotation does not include links between annotations referring to the same entity, we developed a small tool to mark co-reference, given the annotated entity references. Currently, this has to be done manually, but we will explore automatisation possibilities in the future. Given that we can already identify string-identical entity references automatically, it is a manageable workload.

CRETAnno offers an interface to the graph exploration software Gephi, which can be used to edit, explore, inspect and visualise the network (the tutorial covers the annotation, ex- and import, but only basic functionality of Gephi.).

Tutorial

Participants will have the opportunity to work on texts of their own choosing within the first half of the workshop. To that end, they will be asked to submit their texts before the workshop. We will supply hands-on material to participants that do not submit. The tutorial focuses on hands-on sessions and active participation.

Appendix

Tutorial Instructors

All submission authors work jointly in the Center for Reflected Text Analytics (CRETA) at Stuttgart University, Germany.

Sandra Murr

Sandra Murr , is a PhD candidate in the Department of modern German literature at the University of Stuttgart. Within CRETA, she analyzes literary works of the productive reception of J. W. v. Goethe's *Sorrows of the Young Werther*, the so-called Wertheriaden, focusing on the analysis of the central character constellation with respect to emotions.

Maximilian Overbeck

Maximilian Overbeck is a PhD candidate in Political Science at the Chair of International Relations and European Integration at the University of Stuttgart. In his PhD he analyses Western debates on religion in the context of wars and armed conflicts where he uses highly innovative computational-linguistic approaches for the valid and reliable analysis of large newspaper corpora.

Nils Reiter

Dr. Nils Reiter works at the Department of Natural Language Processing and coordinates the scientific work in CRETA. Since his PhD thesis with the title Discovering Structural Similarities in Narrative Texts using Event Alignment Algorithms (Link), he is working in and for the Digital Humanities area, with a particular focus on literary texts, annotation and the operationalisation of Humanities research questions.

Target Audience

Any student or scholar interested in qualitative and quantitative text analysis is invited. Prior knowledge in text analysis techniques is not obligatory but might be helpful. Programming skills are not necessary, but familiarity with Gephi is helpful. We welcome 20 to 30 participants.

Acknowledgements

We at CRETA are grateful to the German Federal Ministry of Education and Research (BMBF) for its generous funding in the years 2016 until 2018 (project ID: 01UG1601).

Transkribus: Handwritten Text Recognition technology for historical documents

Louise Seaward
louise.seaward@ucl.ac.uk
University College London, United Kingdom

Maria Kallio
maria.kallio@arkisto.fi
National Archives of Finland, Finland

Topic

Transkribus is a platform for the automated recognition, transcription and searching of handwritten historical documents. Transkribus is part of the EU-funded Recognition and Enrichment of Archival Documents (READ) project. The core mission of the READ project is to make archival material more accessible through the development and dissemination of Handwritten Text Recognition (HTR) and other cutting-edge technologies.

The workshop is aimed at researchers and students who are interested in the transcription, searching and publishing of historical documents. It will introduce participants to the technology behind the READ project and demonstrate the Transkribus transcription platform. Our team has already conducted 30 similar workshops over the course of 2016, including several sessions with digital humanities scholars and students.

Transkribus can be freely downloaded from the Transkribus website. Participants will be instructed to create a Transkribus account and install Transkribus on their laptops in advance of the workshop. They should bring their laptops along to the workshop.

The workshop will consist of five parts:

Introduction to Handwritten Text Recognition (HTR) technology

The introduction to this workshop will explain how new algorithms and technologies are making it possible for computer software to process handwritten text. Handwritten Text Recognition (HTR) technology works differently from Optical Character Recognition (OCR) for printed texts (Leifert et al., 2016). Rather than focusing on individual characters, HTR engines process the entire image of a word or line, scanning it in various directions and then putting this data into a sequence. This introduction will outline the workings of HTR technology and show examples of the successful automatic transcription and searching of historical documents. It will also explain the possibilities of working with different languages and styles of handwriting. The latest experiments demonstrate that Transkribus can automatically generate transcripts with a Character Error Rate of 5-10%. This means that 90-95% of the characters in the transcript would be correct.

Overview of the READ project

This presentation will give an overview of the READ project and the specific tools it is creating. Computer scientists working on READ are developing HTR technology using thousands of manuscript pages with varying dates, styles, languages and layouts. Testing the technology on a large and diverse data set will make it possible for computers to automatically transcribe and search any kind of handwritten document, from the Middle Ages to the present day, from old Greek to modern English. This research has huge implications for the accessibility of the written records of human history. The READ project is making this technology available through the Transkribus platform but is also developing other tools designed to make it easier for archivists, researchers and the public to work with historical documents. The workshop leaders will present prototypes of some of these tools. These include a system of automatic writer identification, an e-learning app to enable users to train themselves to read a particular style of writing, a mobile app to allow users to digitise and process documents in the archives and a crowdsourcing platform where volunteers can transcribe with the assistance of HTR technology. These tools will be open source and are designed to be used and adapted by other institutions and projects.

Introduction to Transkribus

HTR technology is made available through the Transkribus platform, which is programmed with JAVA and SWT (Mühlberger et al.) A transcription of a handwritten document can be undertaken in Transkribus for two main purposes. The first is a simple transcription – this allows users to train the HTR engine to automatically read historical papers. The second is an advanced transcription – this allows users to create a transcription of a document which may serve as the basis of a digital edition. This presentation will explain both uses of Transkribus.

HTR engines are based on algorithms of machine learning. The technology needs to be trained by being shown examples of at least 30 pages of transcribed material. This helps it to understand the patterns which make up words and characters. This training material is known as 'ground truth' (Zagoris et al., 2012, Gatos et al., 2014). The workshop leaders will demonstrate how 'ground truth' training data can be prepared using Transkribus. Participants can work with images of their own documents, or experiment with test documents already on the system.

Transkribus can also be used simply for transcription. This presentation will explain how to create a rich transcription of a document in the platform, using structural mark-up, tagging, document metadata and an editorial declaration.

Working independently with Transkribus

In the last part of the workshop, the participants will be able to try out the functions of Transkribus on their own laptops. They will be supported by the workshop leaders, who will explain the different elements of the platform and then give participants the chance to practice each function for themselves. The workshop leaders will circulate around the room to answer any questions.

The workshop leaders will demonstrate the following tasks. After each demonstration, participants will be given 10-15 minutes to practice what they have learned.

- Document management – how to upload, view, save, move and export documents in standard formats (PDF, TEI, docx, PAGE XML)
- User management – how to allow specific users to view and edit documents
- Layout analysis – how to segment your documents to create training data for the HTR engines
- Transcription – how to create a rich transcript with tags and mark-up
- HTR – how to apply HTR models to automatically generate transcripts, how to conduct a keyword search of your documents, how to assess the accuracy of automatically generated transcripts

Question and Answer

The workshop will close with a Question and Answer session where participants can clarify anything they are unsure about. They will also have the opportunity to provide feedback on the Transkribus tool via our user survey.

Organizers

Louise Seaward

Dr. Seaward received her PhD in History from the University of Leeds (United Kingdom) in 2013. She is currently a research associate at University College London where she coordinates 'Transcribe Bentham', the scholarly crowdsourcing initiative which asks members of the public to transcribe manuscripts written by the British philosopher Jeremy Bentham (1748-1832). Outside of digital humanities and Bentham, her research interests relate to the history of censorship and the Enlightenment.

Maria Kallio

Maria Kallio works as a Senior Research Officer at the National Archives of Finland where she is responsible for collections, crowd-sourcing and dissemination within the READ project. Currently she is also finishing her PhD in History at the University of Turku (Finland). In addition to digital humanities, her research interests include medieval literacy and written culture in all its diversity.

Proposed audience

Humanities and digital humanities scholars, archivists, librarians, computer scientists

Guidelines for Participants

Participants should register to attend the workshop by sending an email to Louise Seaward. Participants will need to bring their own laptops and install Transkribus before attending the workshop. If participants are interested in working with their own documents, they should bring a selection of digital images to the workshop. Otherwise, it will be possible to work with test documents already on the platform.

Introduction to electronic books: EPub 3.0 and beyond

C.M. Sperberg-McQueen
cmsmcq@acm.org
Black Mesa Technologies LLC, United States of America

Liam Quin
liam@w3.org
World Wide Web Consortium (W3C), Canada

A short introduction to current standards for electronic books, focusing on EPub 3.0 (a standard issued by the International Digital Publishing Federation) and its supporting specifications: XHTML, HTML 5, CSS, SVG, and Zip.

Are the dreams or visions of Ted Nelson, Alan Kay, and other visionaries of electronic books finally coming true? Current tablets, smart phones, and dedicated ebook devices seem to bring them closer to daily reality than ever before. We will survey the current shape of the territory for ebooks: what they can do, what they currently cannot do, what we hope they will be able to do soon. We will demonstrate some of the software available for generating EPubs and for checking them for device- and software-specific problems. Finally, we will outline some outstanding design and production challenges.

Many of the challenges of ebook production will be familiar to anyone with experience in book or journal production: mathematics, tables, graphics, and figures are no easier to handle (but, happily, not always much harder) in electronic books than they are in print publications or on the Web. Others will be familiar from web-site production: ebook readers and applications vary both in terms of what then can do and in terms of how closely they adhere to the EPub specification. The requirement that ebooks be self-contained and work with no network connection brings new challenges, as does the the need for accessible content. Participants will learn how to check against relevant specifications, how to research problems, and how to attain an intuition for the sorts of things that are both possible and practical today.

The International Digital Publishing Federation (IDPF), which developed EPub, has recently merged with the World Wide Web Consortium; we will discuss the outlook for further work in the area and explain how to get involved and how to help ebook readers improve to meet your needs.

Prerequisites: no firm prerequisites. Participants with some familiarity with XML, HTML, HTML 5, and CSS will be in a better position to follow the details of examples.

XQuery for Digital Humanists

Joseph Wicentowski
joewiz@gmail.com
Office of the Historian, U.S. Department of State
United States of America

Clifford Anderson
clifford.anderson@vanderbilt.edu
Vanderbilt University, United States of America

Introduction

This half-day tutorial introduces digital humanists at any level of experience to XQuery, a mature, high-level programming language used in many DH projects because it is purpose-built for analyzing, manipulating, and publishing data stored in the XML-based data formats that many DH projects use, e.g., TEI, EAD, MODS, METS. Prominent XQuery-based projects include Carl Maria von Weber Gesamtausgabe, Foreign Relations of the United States and Syriaca.org.

Led by two experts who each have a decade of experience using and teaching XQuery and who have co-authored *XQuery for Humanists* (forthcoming, Texas A&M University Press), this half-day tutorial introduces the key concepts underlying the XQuery language and the kinds of analysis that it makes possible. The focus will be on exploring TEI-encoded editions with simple XQuery expressions.

Using a free and easy to install XQuery learning environment, participants (who must bring their own laptops) will gain hands-on experience writing queries against open datasets, including a TEI-encoded documentary edition, *Foreign Relations of the United States*. Participants will gain a basic foundation in the language and be introduced to community resources for further study.

This half-day workshop will cover the basics of XQuery, providing participants with sufficient hands-on experience to start exploring their own scholarly editions and metadata with XQuery. We presuppose that participants will have come with a basic understanding of XML and TEI.

Brief outline

I. Introduction: XQuery for the Digital Humanities
II. Setting up an XQuery environment
III. Finding data with XPath
IV. Writing FLWOR expressions
V. Exploring XQuery Full-Text

Each section (except the introduction) will include hands-on exercises.

Target audience:

Students, scholars, and practitioners who use or are interested in using digital methods in their humanities work in academic departments, libraries, "alt-ac" fields, or their private capacity; no previous programming experience required; some experience XML or an XML-based format (TEI, EAD, MODS, METS) useful but not required. Participants will work with a common dataset provided by the tutorial leaders, but they may bring their own datasets for practice during the lab and consultation period.

Tutorial leaders

Clifford B. Anderson is Associate University Librarian for Research and Learning at Vanderbilt University in Nashville, Tennessee. He has a M.Div. from Harvard Divinity School and a Th.M. and Ph.D. from Princeton Theological Seminary. He also holds a M.S. in Library and Information Science from the Pratt Institute in New York City. Cliff started working with XQuery in 2006 before the first official version of the language was released. In 2014, he served as the project leader of the NEH-funded XQuery Summer Institute at Vanderbilt University. He has also taught sessions on XQuery for iterations of Laura Mandel's Programming for Humanists course at Texas A&M and leads the weekly XQuery working group at Vanderbilt University for digital humanists

Joseph C. Wicentowski is the Digital History Advisor in the Office of the Historian at the U.S. Department of State. He received his Ph.D. from Harvard University in modern East Asian history. He started using XQuery in 2007 to analyze and publish the Office of the Historian's TEI-encoded publications and datasets. For more on the project, see Wicentowski (2011). All code and data from the project are freely available on GitHub. He recognized XQuery's potential to empower students, scholars, and practitioners to take control of their own data and build their own applications. But he knew that without resources geared toward people with a humanities background, others would struggle as he first did. He began writing about XQuery in various digital humanities forums, contributing to the XQuery Wikibook online textbook, and giving workshops at the TEI@Oxford and Digital Humanities@Oxford Summer School programs. Joe regularly speaks and writes in the fields of history, documentary editing, and open government. He also actively participates in TEI, XQuery, and digital humanities communities, and fosters discussion about XQuery on Twitter at @XQuery.

XQuery for Data Integration

Joseph Wicentowski
joewiz@gmail.com
Office of the Historian, U.S. Department of State
United States of America

Clifford Anderson
clifford.anderson@vanderbilt.edu
Vanderbilt University, United States of America

Introduction

This half-day tutorial shows how XQuery integrates digital humanities data from multiple sources and formats. Drawing on the latest features of XQuery 3.1, the instructors demonstrate how to draw together information from the most common structured data formats, namely, JSON, CSV, RDF, and XML. We will teach some of the latest features of the XQuery language, including how to work with maps, arrays, and new functions like json-doc(), parse-json() and json-to-xml().

Specifically, we will explore the following data sources: (1) dictionary data (in JSON) from the Oxford English Dictionary; (2) an Open Publication Distribution System (OPDS)-based ebook catalog that makes publications at the U.S. Department of State searchable, browse-able and downloadable via OPDS-compliant ebook reader apps like Shubook, Hyphen, etc.; (3) an OpenRefine reconciliation endpoint API built to let people run their own lists of people against biographical databases; and (4) interacting with IIIF APIs.

Using a free and easy to install XQuery learning environment, participants (who must bring their own laptops) will gain hands-on experience writing queries against open datasets in CSV, JSON, and RDF and integrating this data with XML. Participants will gain exposure to the latest features of the XQuery language as well as best practices for connecting data across systems and formats. We presuppose that participants will have come with a basic understanding of XQuery.

Brief outline

I. Requesting remote data and storing it into an XML database
II. Querying CSV with XQuery
III. Querying JSON with XQuery
IV. Querying RDF with XQuery
V. Enriching TEI with data from other sources and formats

Each section will include hands-on exercises.

Target audience

Students, scholars, and practitioners who use or are interested in using digital methods in their humanities work in academic departments, libraries, "alt-ac" fields, or their private capacity; no previous programming experience required; some experience with XML or an XML-based format (TEI, EAD, MODS, METS, Atom) useful but not required. Participants will work with a common dataset provided by the tutorial leaders, but they may bring their own datasets for practice during the lab and consultation period.

Introduction

Although the majority of Digital Humanities scholars still focus on textual analysis, we see an increasing number of studies using digitised visual sources and taking the first steps in the field of 'Visual Big Data' (Ordelman et al, 2014). Scholars have increasingly used both large-scale digitised visual datasets as well as computational methods to analyse these datasets in new ways, see for example the work of Lev Manovich on Manga comics (2012), Time covers, and selfies (Manovich & Tifentale 2015) or the recent work of Lenardo et al (2016) on visual pattern discovery in large databases of paintings as presented at the DH 2016 conference. Others focus on the identification of finding recurring images in visual collections. Terras & Kirton (2013) analyse the reuse of digital images of cultural and heritage material on the internet while Resig (2014) and Reside (2015) follow a similar approach using a closed dataset.

A similar trend can be observed at the ADHO Digital Humanities Conferences. In 2014 the special Interest group Audiovisual Materials in Digital Humanities was founded and at the 2015 and 2016 conferences, several papers were presented using (audio) visual sources (see e.g. Kleppe 2015, Lenardo et al. 2016, Lincoln 2016). Based on an analysis of the submissions for the 2017 conference, Scott Weingart observes that an increasing number of papers are based on research concerning non-textual sources (Weingart 2017). The use of non-textual sources challenges established research practices of Digital Humanities, leading to new research questions and the need for transformation of existing approaches, and the development of new methodologies. For example, how can we analyse the characteristics of images in large visual datasets? Some of these questions have also been raised in the analogue era. See, for example, the work of Barry Salt (1974) on the characteristics of opening shots of twentieth-century films, Scott McCloud (1994) on the visual language of Japanese manga and comics, or Peter Burke's take on using visual materials as historical evidence (2001).

Due to the digital turn, we now see the application of new techniques to answer similar and new types of research questions. One of the dominant techniques to analyse large-scale visual datasets is computer vision: a field that deals with how computers can generate a high-level of understanding of visual material (Smeulders 2000).This field has been seeing unprecedented improvements as part of the "Deep Learning Revolution" since the first deep Convolutional Neural Network (Krizhevsky 2012), unleashing new possibilities. This workshop will focus on how computer vision can be applied within the realm of Audiovisual Materials in Digital Humanities. During the workshop, attendees will both present (ongoing) work on applying computer vision and experiment with computer vision in their own work in a hands-on session. Possible questions include:

- What are state-of-art techniques in computer vision?
- What are possibilities and challenges in the application of computer vision in Digital Humanities research?
- How can non-expert researchers employ computer vision?

- How can cooperation between Humanities researchers and computer vision experts be improved so both can benefit of each other's expertise?

Workshop outline

The workshop will consist of four pillars:

- **A keynote** by Lindsay King (Associate Director for Access and Research Services Robert B. Haas Family Arts Library, Yale University) & Peter Leonard (Director Digital Humanities Lab, Yale University Library) & on "Processing Pixels: Towards Visual Culture Computation"
- **Paper presentations** with results and ongoing work on applying computer vision in DH research projects. Papers will be selected by a review commission. All details on the Call for Abstracts can be found at the workshop website.
- **A hands-on session** in which participants will be able to experiment with open source Computer Vision tools. This session will be led by Benoit Seguin of École Polytechnique Fédérale de Lausanne, (EPFL). Benoit Seguin is a PhD Student in Computer Science from the DHLAB at EPFL. His work focuses on automatic patterns detection across iconographic collections. Before starting his PhD, he worked with microscope images for biomedical applications or electronic manufacturing problems.
- **Lightning Talks** allowing participants to share their ideas, projects or ongoing work in a short presentation of two minutes. Interested researchers who want to present work will be able to submit their idea in a later stage.

SIG Endorsement

This workshop proposal is endorsed by the steering committee of the Special Interest Group Audiovisual Materials in the Digital Humanities (AVinDH). This will be the third workshop that will be organised by the SIG. The first workshop on audiovisual material in digital humanities took place at the 2014 DH Conference in Lausanne. This workshop paved the way for the foundation of the AVinDH Special Interest Group that was officially launched during the DH2015 Conference in Sydney. The second workshop took place during the DH2016 Conference in Cracow and dealt with audiovisual material and dedicated analysis tools in DH.

While the previous SIG-endorsed workshops were organised by the SIG's steering committee, this proposal on Computer Vision in Digital Humanities is mainly organised by members of the SIG and one representative of the Steering Committee. The steering committee applauds the initiative of the organisers since the theme of the workshop fits perfect in both the SIG's aims as well as the current interest in non-textual sources as observed by Scott Weingart in his first analyses of the DH2017 submissions. Furthermore, the steering committee is enthusiastic about providing a platform for members of the SIG and the complete DH community to present high-quality work that will be selected by a review committee as well as ongoing work that will be presented in lighting talks. Both formats will contribute to the community and network building function that the SIG AVinDH promotes.

Programme Committee

The programme committee (PC) for this workshop consists of the workshop proposers (see list with names and bios below). For the paper selection process, the PC will be extended with at least 10 experts. The selection process will be chaired by Prof. Franciska de Jong, Utrecht University/CLARIN ERIC and chair of the SIG's Steering Committee (f.m.g.dejong@uu.nl)

Composition of the Programme Committee (workshop proposers only)

Dr. Martijn Kleppe

Martijn Kleppe is a researcher at the Research Department of the National Library of the Netherlands (KB) where he works on several Digital Humanities Projects as part of the KB's Digital Humanities Team. Before he worked as academic researcher at the Erasmus University Rotterdam and Vrije Universiteit Amsterdam. He wrote his dissertation on 'Canonical Iconic Photographs' and was involved in several Digital Humanities projects focussing on opening up (audio)visual archives.

Melvin Wevers

Melvin Wevers is in the final stage of his PhD research at Utrecht University on the role of the United States as a reference culture in twentieth-century Dutch newspaper debates on consumer goods. In his research, he primarily focuses on text analysis but he is moving in the direction of computational analyses of visual materials. He also worked on the eScience project *ShiCo: Shifting Concepts Over Time* in which he used word embeddings to study conceptual change in large historical corpora. In Spring 2016, he was a research fellow of the 'culture analytics' program hosted by the UCLA's Institute of Pure and Applied Mathematics. In March 2017, he will be researcher-in-residence at the National Library of the Netherlands (KB) to work on the computational analyses of images in newspaper advertisement.

Mark Williams

Mark Williams is Associate Professor of Film and Media Studies at Dartmouth College. He received both of his graduate degrees in Critical Studies from The School of Cinema-Television at The University of Southern California. He has published in a variety of journals and anthologies, including Télévision: le moment expérimental (1935-1955); Convergence Media History; New Media: Theories and Practices of Digitextuality; Collecting Visible Evidence; Dietrich Icon; Television, History, and American Culture: Feminist Critical Essays; and In Living Color: Race, Feminism, and Television. He directed the Leslie Center Humanities Institute entitled Cyber-Disciplinarity. In conjunction with the Dartmouth College Library, he is the founding editor of an e-journal, The Journal of e-Media Studies. With Adrian Randolph, he co-edits the book series Interfaces: Studies in Visual Culture for the University Press of New England. With Michael Casey, he received an NEH Digital Humanities Start-Up Grant to build the ACTION toolset for cinema analysis. He received an award for Scholarly Innovation and Advancement at Dartmouth for directing The Media Ecology Project (MEP). He has published about MEP in The Arclight Guidebook to Media History and The Digital Humanities (2016), and also in The Moving Image (2016). Most recently Williams has received with John Bell (MEP architect) an NEH grant to build a Semantic Annotation Tool (SAT). With Lorenzo Torresani (Dartmouth Computer Studies) he has received a Knight Foundation grant to develop computer vision and machine learning capacities for moving images.

Thomas Smits

Thomas Smits is completing a PhD on the transnational trade in illustrations of the news and the production of identity by mid-nineteenth century European illustrated newspapers at the Radboud University in the Netherlands. He is an editor of the *Journal for European Periodicals Research* (JEPS) and a PhD-board member of the Royal Netherlands Historical Society. In May 2017 he will start a researcher-in-residence project at the National Library of the Netherlands (KB) entitled *Illustrations to Photographs: using computer vision to analyse news pictures in Dutch newspapers, 1860-1940.*

Benoit Seguin

Benoit Seguin is a PhD student at the Digital Humanities Laboratory of EPFL. His work focuses on using modern computer vision algorithms to navigate large iconographic collections, and he recently showed how Neural Networks could be trained to recognize similar patterns in different artworks. He is part of the bigger REPLICA project which aims at digitizing and making searchable the 1M photos of the Cini collection in Venice. He took part of the organization of the recent "New Methods and Technologies for Art History" Summer School between ETHZ and EPFL. Before starting his PhD, he got his MSc in Computer Science with a thesis about SEM Image Analysis from IBM Research Zurich.

Matthew Lincoln

Matthew Lincoln (Ph.D. University of Maryland 2016) is a Data Research Specialist with the Getty Research Institute, working on the Provenance Index Remodeling Project. He specializes in computationally-driven analysis of art history, including complex network analysis and machine learning methods on cultural datasets. He has previously worked as a curatorial fellow with the National Gallery of Art in Washington, DC, and has received grants from both the Getty and Kress Foundations as part of digital art history summer institutes, and in 2016 was an organizer for a jointly-funded conference "Digital Dimensions of Art History" hosted by the University of Maryland and the Maryland Institute for Technology and Humanities. He has published data-driven research articles in the *International Journal of Digital Art History* and *British Art Studies*, and is a contributor to *The Programming Historian*.

Target audience

This workshop aims to bring together scholars from different fields who have an interest in or actively use computer vision to analyse (large) datasets of digitised audiovisual sources. We have a wide network of peers that can be reached, and will also scan the papers of the conference that have been selected with the aim to invite potential contributors in this realm to present their work in our workshop. We aim at participation of 20 – 30 persons.

Galleries, libraries, archives, and museums (GLAMs) increasingly seek to make digitized and born-digital collections accessible as data optimized for computational methods and tools common to the Digital Humanities. Preparation and publication of collections as data extends possible collection use beyond the analog object interactions that collection interfaces tend to try and emulate. In line with open data efforts, libraries, archives, and museums typically work to assign open licenses to these data. Current access methods are widely divergent, spanning simple provision of compressed collection objects in ZIP files, exposing static collection websites that can be crawled using a tool like rsync, leveraging Github for text collection access, provisioning an API, enabling FTP access to collections, mediating computational processes performed on collection data through a platform, to facilitating data access through use of torrent technology. Concurrently, in response to researcher requests for data-mining, commercial publishers have developed a range of processes for delivering proprietary corpuses with terms and conditions that significantly limit or expressly forbid data sharing, including providing libraries with physical hard drives loaded with the data. There are no consensus-driven best practices that guide the generation, description, and provisioning of computationally amenable GLAM collections for the range of communities that fall within the Digital Humanities. Without best practices in this space, institutions run the risk of misplaced investment of resources that foster the creation of irregular, ultimately disorienting data access environments. Indeed, the panoply of institutional approaches poses a challenge to GLAM institutions seeking best practices and clear guidelines for publishing collections as data.

One major barrier to the development of consensus-driven best practice is an incomplete understanding of *how* digital humanists, among others, are using and reusing cultural heritage data. This workshop aims to make progress towards bridging that gap. Research indicates that types of use exhibited by digital humanists include but are not limited to text analysis, image analysis, mapping, sound analysis, and network analysis. Orientation to the full scope of *academic* use types can be gained through in-depth analysis of data use practices across disciplines as represented in core Digital Humanities journals (Padilla and Higgins 2016), by reviewing works at the annual global Digital Humanities conference (Weingart 2016), and by studying edited volumes that have to this point effectively compiled a broad range of research in this space (Gold 2012; Gold and Klein 2016; Burdick, Drucker, Lunenfeld et al 2012; Schreibman, Siemens, Unsworth 2016).

This workshop will build upon this orientation by engaging directly with digital humanists' existing and projected research and pedagogical practices that draw upon ever growing GLAM collections. Blending short talks by practitioners, guided discussion, and workshopping of the organizers' draft framework (further described below), the workshop will focus on how researchers and educators use GLAM collections that have been made accessible as data, and will extend to consider how these uses should inform collection creation and access.

The organizers of this workshop are members of the project team for "Always Already Computational: Library Collections as Data," an effort sponsored by the Institute of Museum and Library Services in the United States of America through their National Forum grant program. The organizers have observed that GLAM approaches to the preparation of collections as data are often heavily influenced by national or regional priorities and associated infrastructures. Yet the use and reuse of these open data is necessarily international. While the organizers of the workshop are US-based, the workshop aims to surface geographically-diverse praxis. The short talks in the workshop have been selected through an open CFP facilitated by an international program committee.

The workshop may be structured thematically, based on talks and demos solicited via the CFP. Participants will be encouraged to consider how efforts to develop computationally amenable collections, which run the risk of recreating and reinforcing long standing biases inherent in cultural heritage collection practice, provide an opportunity to reframe, enrich, and/or contextualize collections in a manner that seeks to avoid replication of bias.

Potential themes may include:

- **Use and Reuse:** How are data used and reused? What methods and tools are commonly employed? Do these differ by disciplinary community? What types of data are used? What types of data are desired but are difficult to use for reasons included but not limited to copyright status, content type (e.g. video, audio, web, software), size? How, when, and where are data reused? What factors enhance or inhibit the likelihood of data reuse?
- **Access:** What can we learn from our collective experiences working to access data from within and outside of the cultural heritage community? What are preferred methods of data access? What factors should be considered when deciding among access methods? When is simple click and download of bulk collections appropriate? What characteristics define an optimally useful API (application programming interface) for a wide range of users with varying technical expertise? Is an API always the best route to go? Are there a mix of options that should be considered? What considerations inform development of those access options?
- **Description and Discovery:** How do digital humanists locate appropriate data? What tools are used to search for data? What information about the data is necessary to enable use? When compiling meta-collections of data, how are digital humanists maintaining provenance and merging disparate metadata?
