Introduction

The field of the digital humanities has broadened substantially in the last few years, and this expansion has, in its turn, intensified debates about digital diversity and accessibility. These debates have emerged from the realization that, in spite of the euphoria created by visions of a "flat" digital landscape with access for all, the results to date do not measure up to such expectations. New associations with languages and academic methodologies that differ from those of the global North are promoting initiatives to investigate questions of access to technologies associated with the digital humanities. Despite these contributions by organizations such as the Post Colonial Digital Humanities (DHPoCo), FemTech.Net, Transform DH, GO:DH, Associaçao das Humanidades Digitais, etc., the issue of making the digital humanities more diverse and more accessible remains a problem of concern. Questions about race and ethnicity, and about the very material foundations —people, geographies, and tools— that make the digital possible are sometimes lost in discussions about how the digital domain is constituted and distributed across the globe. Therefore, the possibilities, or lack thereof, for taking advantage of digital resources and digital connectivity by people who have been, and continue to be, under-represented in the digital humanities remains to be a topic of some urgency. More conversations are needed across the digital humanities to address and bridge this gap, and to propose more productive ways of thinking about the impact, benefits, and drawbacks of the digital domain as it becomes an increasingly important layer of our cultural and social lives.

It is in the spirit of examining what we have been alluding to as a digital gap that our panel brings together specialists and practitioners of the digital humanities to discuss specific issues in countries and communities that have traditionally been at the periphery of normative cultural representations in various parts of the southern Americas. How are Afro-Latin American and Afrolatin@ communities using methodologies associated with the digital humanities to advance their own goals? How do current digital tools as applied to curatorial projects, archives, and the dissemination of information allow these same communities to explore hidden histories and propose new images and (self-) representations? What kind of digital resources —whether in terms of big-data or minimal computing— are these communities using to intervene in debates about the current state, and the future, of the digital domain? These are some of the fundamental questions inextricably tied to problems of accessibility that our panel will address by means of specific case studies. The diversity of methodologies we will bring to the conversation becomes a strength that productively challenges rigid limits on how the digital humanities are to be defined, which is particularly important when inclusion is at stake.

The session itself will consist of a brief introduction by the panel organizers explaining the rationale for the choice of papers and how these shed light on issues of accessibility in the digital humanities. This will be followed by three presentations, two of which will be in English and one in Spanish (María Cecilia Martino):

International Organization Theory (IO) and Online Afro-Latin America

Yvonne Captain

This presentation will discuss the connection between International Organization Theory, Digital Humanities and the connection of diverse Afro-Latin American political, social and cultural organizations. Professor Captain will show how, using digital tools to reach out to global communities, organizations such as Afroféminas [a Spanish/Latin American organization] help new identities emerge and connect productively. Her paper will hone in on the work of Afro-Costa Rican poet Shirley Barr Campbell, who connects to a variety of organizations via digital tools as a way to draw larger audiences and start discussing what it means to be a citizen of the Diaspora. Her paper focuses on how the advent of digital networks has impacted the formation, membership and digital appropriation of organization that have existed and connected well before our digital boom. In addition, she considers those organizations that have failed in connecting themselves digitally as examples that “proffer a cautionary lesson on what not to do” and as examples on how to handle digital waste.

Towards the Organization of an Afro-descendant Digital Archive in the Cape Verdean Association

María Cecilia Martino

This presentation focuses on the experience of an association of Cape Verdean migrants to Buenos Aires (Argentina) in organizing information by means of a digital archive. In her paper, Mrs. Martino discusses issues of access to technology, the creation of a basic system of metadata and the connection between members of the community based on materials such as photographs, videos, and documents that tell the story of migration and resilience of Cape Verdeans immigrants to Buenos Aires. Finally, her paper will discuss how digital methodologies would help enrich ethnographic practices concerned with representing people's discourse.

Afrolatin@ Digital Humanities

Eduard Arriaga

The final presentation discusses projects carried out by and about Afrolatin@ and Afro-Latin American communities in the Americas, questioning the very definition of Digital Humanities in order to include such initiatives. By analyzing the studied projects, this paper questions conceptions of humanity, humanities, access and digital appropriation residing at the core of current digital humanities projects and put to test by Afrolatin@ and Afro-Latin American endeavors. Finally, the paper reviews some of the principles of the minimal computing approach to identify its limits, advantages and impacts in Afrolatin@ digital projects.

Critical Digital Humanities and Machine Learning

Panel Statement

This panel undertakes a speculative and theoretical discussion of possible future directions for digital humanities work driven by what we call informating, augmenting and automating technologies in the digital humanities. The panel particularly examines the emergence of a new paradigm of artificial intelligence around machine learning, statistical techniques and textual interfaces; a paradigm that challenges the way in which we understand the provision of digital humanities technologies and infrastructures. We explore the debates over informating, augmenting and automating processes that are now starting to emerge in digital humanities, and the historical trajectory that led to the current rapid changes from computational techniques. By looking at how machine-learning infrastructures effect knowledge formations, we engage with these new knowledges and practices, and argue that digital humanities must seek to contest and transform particular institutional structures that are problematic for humanities scholarship.

Although differences have emerged within the digital humanities between "those who use new digital tools to aid relatively traditional scholarly projects and those who believe that DH is most powerful as a disruptive political force that has the potential to reshape fundamental aspects of academic practice" (Gold, 2012: x), it is still the case that, as a growing and developing disciplinary area, digital humanities has much opportunity for these disparate elements to work together. Not unlike differences between empirical and critical sociology in a previous iteration of a contestation over knowledge, epistemology, disciplinary identity and research, digital humanities as a discipline will be richer and more vibrant with alternative voices contributing to projects, publications and practices. Indeed, the debates within digital humanities "bear the mark of a field in the midst of growing pains as its adherents expand from a small circle of like-minded scholars to a more heterogeneous set of practitioners who sometimes ask more disruptive questions" (Gold, 2012: x-xi).

Developing a critical approach to machine learning, for example, calls for computation itself to be historicised, and its developing relationship with humanities to be carefully uncovered. Similarly, by focusing on the materiality of machine learning, our attention is drawn to the microanalysis required at the level of computational conditions of possibility, combined with a macroanalysis of deployment of machine-learning systems in humanities work. This calls for us to think critically about how machine learning is being designed and deployed in the specific problem domains represented by the informating, augmenting and automating of digital humanities. The panel critically engages with these three modes of thought and practice, in order to connect and explore the present and possible future of digital humanities. We develop this approach in the context of these new techniques of knowledge-presentation, new infrastructures for knowledge work, and new formations around human capacities to work with complex and large data sets. Strong claims are often made about the potential for replacing aspects of traditionally humanities work undertaken by human labour alone through machine-learning techniques. Here, through a critical examination of new epistemologies and machine-generated data ontologies, for example, we examine the possibility of methods for a *critical digital humanities* in relation to new machine-learning techniques, together with how machine learning might be repurposed *for* a critical project within DH scholarship.

Towards a critique of machine learning: critical digital humanities and AI

David M. Berry

In this paper I investigate the claims of computational models and practices drawn from the field of artificial intelligence and more particularly machine learning. I do this to explore the extent to which machine learning raises important questions for our notions of being human, but also, relatedly the concept of civil society and democracy as distilled through notions of hermeneutic practice. That is, that in the 21st century we are seeing the creation of specific formations which threaten historical notions of humanities research and thinking. They represent new modes of knowing and thinking driven by these new forms of computation such as machine learning and Big Data, and which will have implications for the capacity to develop and use social and human faculties.

It is certainly the case that through the innovative assembling and organisation of scale technologies together with human actors new cognitive forms are under construction and experimentation. This paper develops a speculative and theoretical discussion of possible future directions driven by what we call Informating or Augmenting technologies in the digital humanities. In this paper, the notion of a digital humanities is linked to the social, cultural, economic and political questions of a recontextualisation and social re-embedding of digital technologies within a social field. Indeed, exploring the digital humanities through a critical lens I seek to understand how different disciplinary specialisms are newly refracted not just by their interaction, but also by the common denominator and limitations of computation. That is, how the constellation of concepts that are used within a disciplinary context are challenged and transformed within a computational frame.

Indeed, this raises theoretical and methodological questions, for example, digital humanities is keen develop tools to explore the new techniques such as machine learning for the field. This calls for a critical response, and there has already been some valuable work undertaken in this area, such as Alan Liu's work on critical infrastructure studies, but here I explore how a critical digital humanities can offer a way of thinking about the theoretical and empirical approach to massive-scale technologies. In this paper I argue that digital humanities should not only map these challenges but also propose new ways of reconfiguring research and teaching to safeguard critical and rational thought in a digital age. First, I turn my attention to research infrastructure and how critical approaches can contribute to and offer methods for contesting ML. I argue that research infrastructures provide the technical a priori for the support of and conditions of possibility for digital humanities projects, but in a machine-learning paradigm different techniques and critical methods will be required to make sense of their use. Secondly, in relation to data, we might consider the more general implications of datafication not just within the general problem of big-data, but in terms of the specific issues raised by machine learning in the generation, processing and automated classification of data–especially where the metadata becomes nonhuman-readable.

This links to my final question about how visibility is made problematic when mediated through computational systems. The question is also linked to *who* and *what* is made visible in these kinds of machine-learning systems, especially where as Feminist theorists have shown, visibility itself can be a gendered concept and practice, as demonstrated in the historical invisibility of women in the public sphere, for example (see Benhabib, 1992). Finally, this paper will explore how to embed the capacity for reflection and thought into a critically-oriented digital humanities and thus to move to a new mode of experience, a two dimensional experience responsive to the potentialities of people and things intensified by the advances in machine-learning capacities. In other words, the reconfiguring of quantification practices and instrumental processes away from domination (Adorno, Horkheimer, Marcuse) and control (Habermas), instead towards reflexivity, critique and democratic practices. As Galloway argues, "as humanist scholars in the liberal arts, are we outgunned and outclassed by capital? Indeed we are–now more than ever. Yet as humanists we have access to something more important.... continue to pursue the very questions that technoscience has always bungled, beholden as it is to specific ideological and industrial mandates" (Galloway, 2014: 128). I argue that specific intervention points within the materialisation of this ML a priori, such as in design processes, can be explored to contest machine-learning techniques that serve to instrumentalise humanities approaches.

Digital humanities has the technical skills and cultural capital to make a real difference in how these machine-learning projects are developed, the ways in which instrumental logics are embedded within them and interventions made possible. For example, digital humanities through its already strong advocacy of open access, could push for and defend open source, open standards and copyleft licenses for technical components and software, opening up and documenting new techniques for machine-learning by humanists for humanists–but this could also be the opening up of the complexity of the black box of ML systems. The ways in which these aspects interrelate in terms of the ML "space of work" is hugely important, that is, the functional capacity of a machine-learning system is crucial, in as much as the range of humanities work may be adversely effected or inhibited by the shape of a machine-learning infrastructural system. I argue that these are urgent questions, with the recent turn towards what has come to be called "platformisation", that is the construction of a single digital system that acts as a technical monopoly within a particular sector, and it is certainly the case that the implications of machine-learning infrastructures and their black-boxed techniques for sorting, classification and ordering large amounts of data needs constant vigilance from digital humanists.

Augmenting and automating human and machine attention in the (digital) humanities

M. Beatrice Fazi

Attention denotes the cognitive process of selecting and focusing upon certain aspects of information whilst ignoring others. In recent years, it has been argued that this special state of percipient awareness is undergoing a profound transformation, due to the increasing intertwining of digital devices and everyday cognitive tasks (see Carr, 2010; Gazzaley and Rosen, 2016). Social media, phone apps, design interfaces, smart devices: the industry markets these technologies as helpful assistants that will free us from the chore of identifying, selecting and retaining relevant information, thus allowing us to dedicate our time, and our mental efforts, to other things. In addition, digital software and hardware are equally used to tune senses and to maintain motivation. Whilst cognitive cognates such as memory and intelligence are of course also targeted, it is the capacity to pay attention that seems primarily to be called into question here. In an attention economy, attention is believed to be a scarce commodity. The assumption is that, with the current information overload, digital machines are instruments able to outsource decisions regarding what to prioritise, what to select and what to discard in the data-deluge. Whilst much concern in the 20th century focused on the question "Can a machine think?", and Artificial Intelligence labs were devoted to answering this question, in the 21st century the central question seems to be "How do we think with machines, and how do we get machines to do much of our thinking for us?"

The exteriorisation of cognitive faculties such as the capacity for attention does, however, come at a price. Studies in neuroscience and neuropsychology, drawing from theories of neuronal plasticity, show that our brain is being rewired in favour of new cognitive skills, and to the detriment of older but cherished abilities, such as the capacity to read a novel from cover to cover. Evidence of this deterioration of human attention comes from science, yet everyday anecdotal confirmations also come from educators and parents, who report of children who cannot focus, and of students who are distracted and cannot complete their assignments. Relevantly, N. Katherine Hayles (2007) has described this situation in terms of a generational cognitive shift.

The humanities, due to the fact that they are largely based around texts, have often elaborated and developed concerns about human attention under the rubric of debates as to what counts as reading. Within the digital humanities, more specifically, it has been stressed that, whilst humans are very good at "close reading" (i.e. the careful, attentive and sustained inspection of a text), computing machines allow us to consider a broader picture. Franco Moretti (2013), amongst others, has called this condition "distant reading". These debates have opened up considerations about the possibility of an "algorithmic criticism" (Ramsay, 2011), as well as reflections on the importance of the hermeneutic faculties of human beings (Berry, 2012; Stiegler, 2010 and 2016). In this paper, I depart from these discussions within the digital humanities and then move to argue how new understandings of human attention might emerge in conjunction with possible conceptions of what I call "machine attention". I will map these possible conceptions of machine attention in relation to increasingly popular Artificial Intelligence techniques known as machine learning. More specifically, I will consider how machine-learning programs might be said or seen to pay attention to data-stimuli: they detect some information and discard some others, forming and dissolving patterns, in order to shape and sharpen their cognitive outcomes based on these selections. I will then emphasise the relevance of these modes of machine attention for the way in which we can understand what human attention might become after the computational turn in the humanities.

The question of what is happening to human attention is an important and pressing one for the humanities. It is always difficult to define what the humanities are, or where they begin and end. However, surely few would object that the humanities are the locus of "deep" attention: humanities disciplines prioritise textual analysis, where the process of knowing is intimately connected to those of making sense, interpreting, and of giving meaning. These are epistemic processes that start and end with the cognitive exercise of attention. The pedagogical issue of what happens to students if they have lost (or never gained) the capacity to focus is also a question upon which the future of humanities disciplines, and humanities departments, seems to be predicated. In this paper I will address these issues, by considering the intermeshing of human and machine modes of attention, whilst also arguing that our engagement with automated forms of attention (as well as of other automated and augmented cognitive processes) should involve a commitment to re-defining and enlarging the prospect of what computational mechanisms are, and what rule-based, computational cognitive processes might amount to.

'The new spirit of automation': the changing discourse of automation anxiety

Caroline Bassett, Ben Roberts and Jack Pay

From self-driving cars, through high-frequency trading to military drones and organised swarms of shelf-stacking robots, our era is marked by rising automation and a new fascination with the likely social, cultural, and economic impacts of this computationally driven transformation. This paper will explore innovative methods by which the humanities might address contemporary *automation anxiety*. The wider topic of automation is a pressing subject with various existing academic responses such as Frey and Osborne's work on automation and the future of employment (2013). The focus of this paper is to address, as a topic in its own right, the cultural and social anxiety generated by these new forms of computational automation. What new research methods can the humanities use to map and understand automation anxiety around opaque computational decision making? What digital tools can be brought to bear on the diverse types of online public culture in which this anxiety is expressed?

Automation anxiety is evident in a plethora of popular contemporary accounts, public debates and political interventions. Tyler Cowen's *Average is Over* depicts a dystopian future in which the job market is divided between a highly educated and skilled elite capable of harnessing automation for personal wealth creation and a wider mass who are consigned to low paid work. Other accounts see in this new wave of computerisation the potential for a productive redefinition of the relationship with work. Futurists Martin Ford in *Rise of the Robots* (2015) and Jerry Kaplan in *Humans Need Not Apply* (2015) propose to respond to the automation of work through the creation of a universal income. In a more radical version of this thesis, postcapitalism, as charted by Paul Mason, posits automation as the basis of a technologically-driven, non-market successor to capitalism. Another type of anxiety arises out of the increasing use of computerisation in law enforcement and military action. Here there is an automation anxiety that the current wave of military drones will evolve into fully autonomous killing machines, with software systems governing decisions about life and death. In July 2015 over 3000 robotics and artificial intelligence researchers and over 17000 other academics and interested parties (including Stephen Hawking, Elon Musk and Noam Chomsky) signed an open letter, published on the Future of Life website and widely disseminated in the global media, calling for a global ban on "offensive autonomous weapons beyond meaningful human control." There is also a more general anxiety which asks what happens to human life when so many tasks are automated away. Nicholas Carr's *The Glass Cage: Where Automation is Taking Us* (2014) suggests that automation is a threat to humanity itself—as we delegate tasks to computational tools, human cognitive capacities atrophy, understanding weakens, and the power of human reasoning is undermined.

This paper places contemporary automation anxiety in the context of historical debates about automation. It examines methods that might be used to analyse changing social attitudes to automation and computation between the 1960s and the present. Automation was a controversial topic in both Britain and the United States in the 1960s. In 1964 defence automation specialist Sir Leon Bagrit gave the public BBC Reith lectures on the topic. In the same year, President Lyndon B. Johnson set up the National Commission on Technology, Automation, and Economic Progress. Then, as now, there were concerns about automation and the future of employment. Then, as now, there were utopian imaginings of the future social benefits of automation. Nevertheless the hypothesis here would be that there are important differences between the two eras and that we can learn from changing attitudes to automation and computation. Among other things, analysis of changing attitudes to automation might illuminate different historical perspectives on: the end(s) of work; the relationship between labour and the domestic sphere; the role of computation in society.

The paper takes inspiration, but not theoretical orientation, from Boltanski and Chiapello's *The New Spirit of Capitalism* which used textual analysis of management literature from the 1960s and 1990s to argue for a fundamental shift in what they call the 'spirit of capitalism', i.e. the way in which capitalism justifies itself. In a similar vein we analysed key grey literatures (policy, commercial reports, academic and government papers) on automation from the 1960s and present in order to understand the changing discourse around automation. A key concern was to use digital humanities tools which provide different scales of analysis and new perspectives. We did this both to generate new understandings of automation anxiety across time and to investigate ways in which digital humanities and media archaeological approaches intersect.

The "new spirit" of capitalism which has emerged between the 1960s and the present day consists in a highly decentralised networked form of capitalism, characterised by "flatter" organisational hierarchy, much greater autonomy within firms for both individuals and teams, lower job security and the proliferation of temporary contracts and outsourcing. Boltanski and Chiapello use their sociological analysis of management literature to support a more speculative, philosophical account of capitalism and its critique, notably seeing the contemporary spirit of capitalism as incorporating the critiques that were made of capitalism in the 1960s and particularly around May 1968.

Similarly this paper argues that automation controversies could be a springboard to more general debates about the changing relationship between computation and society. The central premise here is that there is a much to be discovered from *attitudes to* automation and the justification of computation tools as there is from the specific technological forms and implementations of automation.

This panel brings together three projects that explore and analyze annotated texts in digital environments: The *Archeology of Reading in Early Modern Europe*, The Winthrop Family on the Page, and Derrida’s Margins: . All three projects seek to give users the experience of how another person read their books (see Notes). While each is fascinating in its own right, collectively these projects span centuries and provide a powerful and instructive lens on data modeling, inter-institutional collaboration, and interoperability.

The connections between these projects, both on a scholarly and an institutional level provide a powerful case study in creating distinct but interoperable digital humanities projects and resources. Both Winthrop and Derrida’s Margins are being built in the Center for Digital Humanities at Princeton University, while AOR is a collaboration between Johns Hopkins, University College London, and Princeton. AOR and the Winthrop project share a co-PI, Anthony Grafton, and two books owned and heavily annotated by John Dee are in the Winthrop library and thus came to New England. However, while the AOR project looks at a single renaissance annotator (Gabriel Harvey in Phase I– the project is heavily indebted to the methods and questions outlined in Jardine and Grafton, 1990–, and John Dee in Phase II), the Winthrop project looks at generators of annotators (men and women) making it as much a prosopographical project as a study of annotation. Like AOR, Derrida’s Margins focuses on a single scholar’s interaction with his library, but Jacques Derrida’s annotation practices differ dramatically from Harvey or Dee, and French copyright law poses serious challenges to representing the book pages online.

All three projects make use of the International Image Interoperability Framework, but differ on the rest of their underlying data structures. AOR uses a custom XML schema to encode a critical edition of the annotations. Winthrop will use a custom prosopographical-bibliographical relational database, implemented in Django. While most of these relationships will be attested through annotation, the system will also record other connections (including purchasing records, books referenced in letters, etc). The annotation data model will most likely be created using a graph database, given the multiple types of annotations and the ways they can be expressed. Derrida's Margins will be another custom relational database, built in Django, but will be fully bi-lingual, allowing users to search and browse in English and French. The Winthrop and Derrida database will also be exposed as Linked Open Data.

All three projects are committed to interoperability, with a key goal being the ability to search across the three projects once they are complete. The projects are in close contact the IIIF Editors and the W3C Web Annotation Working Group to ensure adherence to and input on best practices and emerging standards.

The Archaeology of Reading in Early Modern Europe

Earle Havens, Matthew Symonds,
Anthony Grafton

The Archaeology of Reading in Early Modern Europe (AOR), is an international collaboration among the Sheridan Libraries at Johns Hopkins University, the Centre for Editing Lives and Letters (CELL) at UCL, and the Center for Digital Humanities at Princeton University Library, with funding from the Andrew W. Mellon Foundation. It is also an interdisciplinary collaboration between historians, librarians, software engineers and data scientists.

While the body of scholarship on the history of early modern reading practices has burgeoned during the past several decades—guided in large part by the initial scholarly work of our project partners, the late Professor Lisa Jardine and Professor Anthony Grafton—as a collective body of knowledge the history of reading has nonetheless remained limited to isolated, partial, and impressionistic studies of single texts read by single annotators.

As researchers, we conduct this work in the conspicuous absence of comparative evidence of the larger range of early modern historical reading practices, strategies, and agendas. Scholars also find it physically impossible to effectively penetrate the dynamic array of information preserved in annotated books for the purpose of systematic analysis owing to their sheer density of content, in many instances, relative to the original texts on which the annotations comment.

During the original planning workshop on annotated books that led to the formation of the project, leading scholars, librarians, curators, and technologists agreed collectively that these constraints imposed upon the study of early modern annotated texts in their original analog form could only be overcome satisfactorily when annotations are treated as data sets that can be mined and analyzed effectively in more versatile, enriched, and readily searchable digital forms.

The AOR team has elected to focus on a distinct and roughly contemporary dyad of clearly identified early modern readers: Gabriel Harvey in Phase 1 (2014–2016) and John Dee in Phase 2 (2016–2018). While the identities of a large majority of early modern annotators remains unknown in extant collections, this focus on known readers will enable the project team to analyze and more precisely situate the processes of reading and annotation within their respective historical contexts.

In order to make these sources more accessible to analysis, the AOR technology team – based at Johns Hopkins University's Digital Research and Curation Center – is working closely with the International Image Interoperability Framework (IIIF) protocol and community to develop features and use cases that will enhance AOR within this larger framework.

IIIF features a set of protocols, application programming interfaces (APIs), and shared technologies for the presentation of web-based images. In the case of AOR, these images are digital surrogates of rare book materials containing manuscript annotations by Gabriel Harvey and John Dee, which users interface through AOR's adapted version of the Mirador (version 2.0) viewer. The technical infrastructure for AOR includes a data archive, an image server, a IIIF image service, a corresponding IIIF presentation service, and the IIIF-compliant Mirador viewer.

The data archive for this project provides the framework for long-term access to, and preservation of, all project content: an important contribution to Digital Humanities more generally, insofar as this issue has not yet been unaddressed within IIIF. The technology team has defined an archival data model that can be mapped to other data models for data access and presentation over time. Another layer of the infrastructure that has been developed in Phase 1 of AOR consists of an image server that accesses content from within the data archive. Currently, the team is utilizing a commercial FSI image server, though comparable image server resources (e.g. djatoka) may also be used.

While AOR has been deployed using the versatile Mirador 2.0 API, the AOR technology team has developed IIIF endpoints for any available image service and presentation service, so long as they can be accessed by an IIIF-compliant image viewer. All AOR data can be accessed through our Mirador2 IIIF-complaint viewer, which has been specifically enhanced to meet the use requirements identified by the team for both current and future users. Over the course of AOR Phase 1, the technology and scholarly teams have worked together closely to define and implement a set of use cases related to image viewing and manipulation, transcription viewing, and dynamic, query-building search capabilities.

The current AOR viewer is the culmination of this iterative development process, which presents users with a wide-ranging set of functionalities aimed at enabling new forms of research on the history of reading practices. One new method is informed by the use of insights gleaned from the data generated throughout Phase 1 to formulate new research questions for the humanities team to investigate.

By creating a corpus of important and representative annotated texts with searchable transcriptions and translations, we can begin to compare and fully analyze early modern reading, and place that mass of research material within a broader historical context. In so doing, we could also approach—not in isolation but as a dynamic, internally and institutionally complimentary, research team—the traditionally subjective study of reading in a demonstrably empirical, comparative, and systematic way.

All visible interventions by readers in the books – marginal notes, underlining, marks and symbols, et cetera – have been marked up according to a non-TEI XML schema developed by humanities and technology teams working in close cooperation. The Phase 1 corpus of thirteen books owned and annotated by Gabriel Harvey has generated 3,355 XML files, each representing a single page of an annotated book. The data contained within these XML files has allowed us to map the language Harvey used in his own annotations and highlighted in the original printed texts, to find interesting correlations, and to use those correlations to form new investigations into the history of reading, Harvey's own biography, and the wider history of ideas in the early modern period.

Derrida's Margins: Annotations from the Personal Library of Jacques Derrida

Katie Chenoweth

This paper will give an overview of Phase One of the Derrida's Margins project currently underway at the Center for Digital Humanities at Princeton University (CDH).

Derrida's Margins is a longterm project that aims to create a website and online research tool for annotations from the Library of Jacques Derrida, an archival collection housed at Princeton University Library's Rare Books and Special Collections that was first opened to the public in March 2016. Phase One of Derrida's Margins focuses on annotations related to Derrida's landmark 1967 work De la grammatologie, first translated into English in 1976 as Of Grammatology (hereafter OG, see Spivak's 2016 translation. This corpus will serve as a pilot data set for future work, allowing us to establish protocols, workflow, and a relational database model.

Jacques Derrida is one of the major figures of twentieth-century thought, and his personal library represents a major intellectual archive. The Derrida Library, consisting of about 19,000 published books and other materials, represents a lifetime of reading. But for Derrida, the act of reading was not a passive process: he engaged — even grappled — with what he read, covering pages with notes and cross-references, inserting other handwritten materials, quoting and adapting what he read into what he wrote. As Derrida himself said in an interview later in his life, his books bear "traces of the violence of pencil strokes, exclamation points, arrows and underlining" (for details related to Princeton's acquisition of the Derrida Library, see the article posted by Princeton University Libraries, 2015).

It was in OG that Derrida first articulated a new style of critical reading, which would become the foundation of the philosophy of "deconstruction." Our online research tool will enable scholars to study the development of this philosophy in an unprecedented way by providing comprehensive digital access to the material annotations, marginalia, bookmarks, and other notes from Derrida's library that correspond to each quotation and citation in OG. Beyond making Derrida's annotations available digitally for the first time, this project seeks to enable researchers to understand the relationship between Derrida's published writing and his reading practices. As we move beyond OG in future phases, the website will also allow researchers to gain new insights into Derrida's library and his published writing as networks of texts, citations, and annotations.

OG was chosen as the pilot text not only because it is a foundational text for deconstructive reading, but for two additional reasons: 1) it is among the most widely read of Derrida's works and, according to Google Scholar, by far the most frequently cited, constituting more than 10% of the total citations for Derrida as of November 1, 2016; 2) 2017 will mark the fiftieth anniversary of the initial publication OG, and a number of scholarly conferences and events are scheduled to discuss the text and its legacy.

In Phase One, we began by identifying all instances of citation (quotations, references, footnotes, etc.) in OG that lead us back to books and other reading materials from Derrida's library. Each cited work from OG is entered into a Zotero library, which will eventually form the basis of a public bibliography for OG. We then located these references in Derrida's copy (or, often, multiple copies—different editions, translations, etc.) of each work. Each instance of citation is given a tag in the Zotero library that indicates the source page from OG, the type of citation, the page number(s) in the cited text, whether or not the volume is present in Derrida's Library at Princeton, and the presence or absence of annotation (here construed as a mark of any kind, verbal or non-verbal). Next, we will transcribe all marginal annotations and other markings, limiting ourselves to tagged pages, i.e., those that are explicitly referenced by Derrida in OG. Digital images and transcriptions of these annotated pages will form the basis of the website, allowing users to go "behind the scenes" of Derrida's reading practices.

Given that Derrida's work is widely read in the United States, France, and around the world by scholars from numerous disciplines in the humanities and social sciences, we anticipate that the audience for this project will be broad and international. The more targeted audience would be specialists of Derrida and deconstruction, as well as researchers in philosophy, literary studies, and intellectual history.

One major risk this project faces is the question of French copyright restrictions. Due to the fact that the majority of books owned by Jacques Derrida are copyrighted works whose copyright is still in force, there is a question regarding the legality of posting digital images of sections of those books on our website. Despite the fact that the copies of these works in JD's library have been annotated by the philosopher's hand, the works themselves are the intellectual property of their respective publishing houses in France. Pending clarification by the Office of the University Counsel regarding the amount of risk we are at liberty to take in this respect, we will make a decision as to the amount of text from those works that it is acceptable for us to display on our public website.

This project is intended as the first phase in a long-term project. Team members in Phase One will create a manual detailing their work process and workflow to facilitate and standardize the project going forward. At the end of our pilot phase with the CDH, we will have the following

The main outcomes and deliverables of this project are the following:

- Bibliography of *De la grammatologie,* made available as public Zotero library
- Digitization of all relevant pages from the Derrida library
- Customized grayed-out images, if necessary
- Annotations transcribed, translated, and tagged
- Custom designed relational database to record and analyze Derrida's annotation practices and the anchor text they reference
- Bi-lingual (French and English) Web portal created in Django to allow users to search and browse the annotations
- Transcriber's manual

The Winthrop Family on the Page

Anthony Grafton, Jennifer Rampling, Christian Flow

"The Winthrop Family on the Page" will employ an extensive database of bibliographic information, biographical data, and marginal annotations to allow digital exploration of early modern lives and learned practices. Centering on the surviving library holdings of the storied Winthrop family, whose representatives included such prominent figures as John Winthrop, a founder and governor of the Massachusetts Bay colony, the final product will be a web platform affording a dynamic sense of how colonial readers interacted with texts and fellow readers. Users will be encouraged to follow the story along multiple axes, both diachronically—as family members communicated across decades, even centuries, in the margins of their shared books—and synchronically, as single readers followed references from one text to the other, leaving a bread-crumb trail of notation along the way. The experience will be further enriched by inclusion of information on how the Winthrops' books surface in other historical sources they left us, including journals and correspondence, ensuring once again vivid access not just to the texts, but to the people who read them.

The bulk of the project's database will consist in entries for some 300 books formerly owned by the Winthrops and currently held at the New York Society Library. Aside from bibliographical information for all of these books, the database will include a second module treating the marginalia they reveal. Here, the project will log the location of all manuscript notes in the collection; in addition, for a select, smaller subset of 50-60 books, high-quality digital images will allow users to view the marginal material directly. Several representative notes from the same sub-set will be translated and transcribed along with relevant anchor text, and all of the collected data will be encoded for search. Users will be able to come to the collection with queries about everything from annotations of a particular era, to those of a particular person, to those presenting a specific sign (e.g., the manicule) or handling a specific theme.

The defining characteristic of the project is its deft exhibition of a very particular source-base. The rich surviving Winthrop holdings, coupled with the opportunities for collection and display afforded by a digital platform, offer a rare opportunity to excavate and reassemble an Early Modern book collection, giving a concrete frame to the "intellectual space" within which the family lived and thought. Still more exciting is the chance to fill that space with dialogue: the project's careful curation, transcription, and (when necessary) translation of the marginalia that the Winthrops recorded as they read allows users to follow their intellectual journey between books and between generations. Those generations spanned not just time but space: because the Winthrops were a colonial family, their New England library had its roots and its first readers in Europe. Users of the collection are therefore positioned to pose and answer questions about how Early Modern knowledge made the transition from the Old to the New World. How, we wonder, might our understanding of the Salem Witch Trials be affected when we take into account the fact that Wait Still Winthrop, the Chief Magistrate of Massachusetts, could well have perused the marginal annotations of his European ancestor, Adam Winthrop, in the witchcraft section of the family library? How did reading and annotation practices originally cultivated in England filter into the learned arsenal of later colonial readers?

Queries like these are made actionable by the labors of a highly-skilled team: specialties in book history and annotation, in ecclesiastical history, in alchemical practice, and in the classical tradition will be amply represented. The project itself, which will offer direct access to an array of understudied material, is meant to have wide interdisciplinary appeal. Situated at the nexus of digital humanities and history of the book, straddling Europe and the colonies, the domains of intellectual history and learned practice, it will resonate with historians of Europe, America, and the Atlantic World; book historians; librarians; historians of science, medicine, and religion; and users outside the Academy. And in future years the appeal will only grow more broad-based, for project members hope to build outward from the corpus on which the 2016-17 work is founded. The more material at hand, the richer the web of connections users will be able to make between books and readers. There are several possible modes of expansion: (1) full imaging, transcription and translation of all books in the NYSL corpus (that is, including those beyond the subset currently targeted for the pilot-phase of the project); (2) inclusion of further Winthrop books housed at other major repositories, including items from the eighteenth and nineteenth centuries (when the Winthrops added hundreds of new books to the library, including a collection of almanacs now housed at the Houghton Library, and the bulk of the collection of Winthrop books at Allegheny College); (3) development into a broader study of Colonial reading practices and knowledge networks, involving other family collections of annotated books, such as the Mather Family Library, now held at the American Antiquarian Society; the library of Thomas Prince, now at the Boston Public Library; and the library of James Logan, now at the Library Company of Philadelphia.

Notes

1. There are a number of projects dedicated to recording annotations or marginalia, notably the crowd sourced Annotated Books Online and Book Traces. The three projects discussed in this panel proposal differ in that they are specifically grouped by annotator and want to answer specific questions about the worldview and read patterns of known annotators. They are also designed to facilitate more complex queries. These projects are also addressing a different question from other annotation projects such as Annotation Studio which are designed for modern readers to annotate digital texts.

Introduction

The panel contributions will introduce and discuss several central aspects of DARIAH-EU aimed to support emerging practices in the Digital Humanities, to disseminate consolidated practices and to provide tools for navigation through the rich and changing landscape of the productions of research communities, be they research data, tools, methods or other assets.

Our focus point is how to boost research on a number of different levels: ensuring the sustainability of the infrastructure, its "scaling up" to enable better access to research data, community-building, linking teaching activities and weaving the network of affiliated initiatives.

Panel Overview

Chad Gaffield (Moderator)

Panel participants as listed below will introduce their topic for 5 minutes each, followed by a general discussion.

It has been much debated in the Digital Humanities communities whether scaling up – in terms of shared resources, formation of team science, cross-domain research – is at all appropriate for the way knowledge is produced in the various humanistic disciplines. Instead of tackling again this general problem, this panel takes a much more practical approach. There can be no doubt that research practices in the humanities and social sciences are profoundly changing (Wouters et al., 2013). The turn to digital methods happens in a relationship of mutual dependency and co-evolution with the infrastructures traditionally feeding humanities research: collections, libraries and archives. This development is most visible in large-scale research infrastructures such as CLARIN and DARIAH, and it is acknowledged by their respective funding.

This panel presents the efforts made within the DARIAH (Digital Research Infrastructure for the Arts and Humanities) community in its mission to further develop the Arts and Humanities research infrastructure, now that the Digital Humanities have long left the incubation stage or the phase of early adopters. The field is still growing but also starting to differentiate and specialise. The “scaling up” of the humanities refers to the growth of the community – as a social, cognitive and technological network –, the increasing availability of Big Data, the ongoing penetration of standards and the use of consolidated tools. While the mission is quite clear, its implementation is a far more complex process.

We will focus on the relevance of the **community** and **sustainability** as driving factors in building the research infrastructure**.** The contributions report about lessons learned, examine achievements and open questions, and aim to engage with the audience about their expectations, experiences and visions of what a research infrastructure (RI) for the Arts and Humanities should look like.

These two aspects are not arbitrary. Community-building responds to the motto of DARIAH: *services developed for researchers by researchers* and is relevant to formulate needs, to find appropriate technical solutions but also to encourage continuous (re)use by means of education and training. DARIAH itself is a pan-European infrastructure, driven by grass-rooted needs of researchers, and governed by national representatives, entailing processes of collaborative evaluation. In addition to community-building within the RI, DARIAH has always aimed to expand and strengthen the external cooperations with a broader ecosystem involving both affiliated RI projects (EHRI, CENDARI, PARTHENOS) and sister initiatives like CLARIN, as well as with research infrastructures that specialize in providing basic services (eduGain, EGI or EUDAT). Research Infrastructures address both their users and producers with their immediate needs. At the same time they have to be stable, reliable and of good quality, which needs to be addressed continuously throughout its life. Another primary concern of DARIAH is the focus on reuse of research data and ensuring their longevity. This is where the sustainability of software and services comes into play, ensuring the continued availability of the outputs from shorter-lived projects in the long run.

Building a durable infrastructure

Nicolas Larrousse and Paulin Ribbe

During the last decades, digital made his way into the Arts and Humanities research world at every stage of research projects. As a consequence, the way researchers work today has considerably evolved. They can no longer work isolated and their work requires more and more sophisticated tools to deal with research material. There is a need to scale up and build infrastructures dedicated to Arts and Humanities. DARIAH is one possible answer to these new requirements.

DARIAH is organized as an European framework for research infrastructures based upon a consortium of states which agree to support the infrastructure in the long term. It was designed to establish sustainable digital services and develop common practices. Such objectives reflect a long-term vision which would not fit in a “classical” project funded for three years.

Within the consortium, ongoing efforts help to concretely build the infrastructure and to better answer those fundamental questions: what is an infrastructure for Arts and Humanities and how can we build it on the European level?

DARIAH contributions and the reference architecture they inhabit

Mike Priddy (Co-authors: Francesca Morselli, Lisa de Leeuw, Andrea Scharnhorst)

DARIAH constitutes itself as a pan-European infrastructure and relies on national contributions from its member states. 90% of these contributions are in-kind and represent the research outputs that each member country contributes to the infrastructure, showing the richness and diversity of the European research landscape. DARIAH is creating a way to collect, disseminate, review, assess and evaluate the contributions made to the infrastructure and community.

As researchers in the Arts and Humanities familiarise with the creation, management, storage and reuse of data, they need a technical infrastructure that can support such activities. On the other hand, a mere technical support seems insufficient to sustain their research activities, as research communities play a crucial role in the development of the infrastructure by developing processes and offering services and resources. An approach which supports the knowledge creation process as well as an agreement on standardised processes (e.g. data exchange) is therefore highly needed.

With a reference architecture we aim to create a common language among the European member countries per individual type of contribution to describe and communicate DARIAH contributions, as well as provide a reference for other projects and infrastructures in the Arts and Humanities.

Re-usability of tools and services

Carsten Thiel

The software tools and solutions powering the services provided by infrastructures are subject to their individual life cycles. While most projects realised through research grants focus on the initial phases – from inception and initial design, through user testing and design revisions, to beta releases –, delivering a "final" product by the project's end remains the primary objective. But the software's life does not end there. As researchers use the tools, new needs and requirements can arise that need to be addressed and implemented. At the same time the IT world evolves and technologies change. This leads to an increased need for adopting existing services and their underlying software for continued usability. Finding resources to sustain the services and to ensure their availability and accessibility requires a change already to the initial objectives in the development phase (see Doorn, Aerts, Lusher 2016). Designing software from the get-go with re-usability in mind ensures the long-term benefit of enabling future contributions and adoptions needed by the community as a whole.

Teaching: where and how?

Aurélien Berra

DARIAH's "Research and Education" programme has contributed or planned several services which emphasize how data are central in building up a sense of community and deliberate, open, collaborative research strategies.
Three projects will be discussed. The Digital Humanities Course Registry is a collaborative database aiming to provide up-to-date information on European courses to students looking for a programme and to teachers and researchers interested in evaluating the state of the field at a national or international level. The initiatives comprised in the "Integration of Training Material" project offer a framework for sharing and preserving Digital Humanities teaching materials (through the user-centred design of #dariahTeach, an open platform for extensible and translatable contents,) as well as a philological toolbox based on the principle of re-use and adaption (Biblissima's BaOBab, a catalogue of online tools, guidelines and tutorials focused on manuscripts traditions,). The Master Classes scheduled for 2017 in Maynooth (Public Humanities), Florence (Evaluating Digital Scholarship), Berlin and Paris (Data Reuse in the Humanities) are designed as experiments in developing a format which will engage advanced users and foster a collective reflection on "data fluidity" (see Romary, Mertens & Baillot 2016).

DARIAH & affiliates (aka "DARIAH's outer network")

Matej Durco

Despite the vast diversity of the individual research agendas, at a certain level all research infrastructures and initiatives need the same kind of basic facilities represented by the lower levels of the architectural stacks – stable hosting and storage of data, processing and computational capacity, secure authentication to build trust, stable referencing of resources, etc. DARIAH has always embraced the idea of cooperation between the different initiatives to harness the synergies emerging from this shared needs and has strong ties both "horizontally" to affiliated RI-projects (EHRI, CENDARI, PARTHENOS) and to sibling infrastructures like CLARIN, as well as "vertically" to networks that specialize on the actual provision of these basic services like eduGain, EGI, or EUDAT. This is in line with DARIAH's self-image as a facilitator that speaks the language of the researchers, but also has the "global critical mass" and expertise to approach and negotiate with large technical infrastructures.

Introduction

This panel brings together papers by three projects that are working on digital methods for researching and representing the textual networks of women writers. "Documentary Social Networks: Women Travel Writers in Prosopographies," by Alison Booth with Worthy Martin, Rennie Mapp, and Jeremy Boggs, focuses on a cohort of travel writers from the Collective Biographies of Women project to consider documentary social networks and the "sibling" relationship of subjects who occupy a single biographical volume. "Intertextual Networks: Theorizing and Encoding Textual Connections in Early Women's Writing," by Sarah Connell and Julia Flanders, presents the Women Writers Project's (WWP) work on using markup to model and research the citation and quotation practices of early women writers in the context of the larger ecology of digital projects focused on gender. "Digital Representation, Intertextual Relationships, and the Impact of Early Modern Women's Writing," by Marie-Louise Coolahan and David Kelly, describes the research of the RECIRC project (The Reception and Circulation of Early Modern Women's Writing: 1550–1700), focusing on RECIRC's development of taxonomies of reception and circulation and on the methodologies for understanding textual transmission that the project has been testing.

These projects explore the problem of intertextuality at several different levels: primary source documents (including print and manuscript), metadata, and synthetic or critical narratives such as biography and annotation. Each project faces the challenges particular to its own place in the digital ecology and also the challenge of making its data usable in other parts of that ecology: connections that will depend on the collaborative generation of digital standards. The projects also share an interest in understanding the roles that gender played in the circulation of texts, investigating what women read and cited, which women were read and cited, and how women were represented in writing. Together they offer an opportunity to explore how intertextuality, as understood in the context of the modern web of linked open data, operates not only as a deliberate rhetoric of quotation but also through more complex interconnections between texts, authors, and other cultural agencies—and how those links can effectively be brokered through connections between digital research projects and resources.

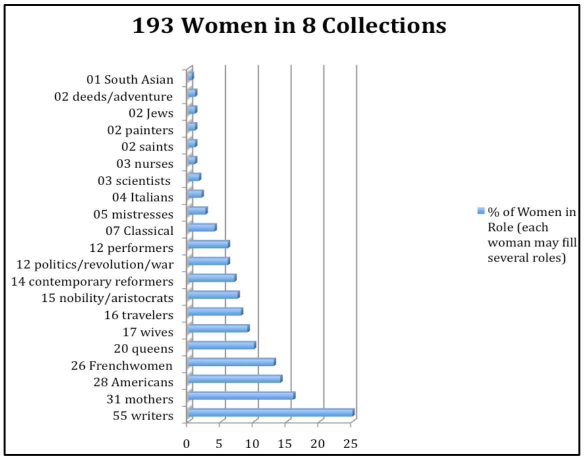
These three papers will not only discuss the various textual networks of women writers that are the subject of their individual projects but will also consider connections between the projects themselves, highlighting both points of contact and distinctions. We see this panel as an opportunity to examine the wider possibilities for making intertextual connections legible among digital systems of textual circulation.

Documentary Social Networks: Women Travel Writers in Prosopographies

Alison Booth with Worthy Martin, Rennie Mapp, and Jeremy Boggs

New literary histories using large digitized corpora can scale up the longstanding interest in intertextuality, beyond allusions and acknowledged influences. Such projects as the Women Writers Project and RECIRC engage not only textual but also personographic data, as all kinds of metadata interdependently form rigorous measures of intertextual transmission. As feminist literary history, such projects are also committed to contexts of women's lives and networks of representation. The Collective Biographies of Women (CBW) project studies Anglophone prosopographies (collective biographies, or a quantitative approach to standardized lives in sets) women of all occupations in books published since 1830, revealing trends in representation of women through an annotated bibliography, a database and stand-aside XML markup of narrative structure and discourse (Biographical Elements and Structure Schema, or BESS a stand-aside XML schema for marking elements of biographical narratives at the level of the paragraph). Unlike many feminist DH projects, CBW is not an archive of women's creative writing, though at least 700 of 8700 persons in the database are writers (one person is likely to represent several types). We study the collocation of women in books; thus Harriet Martineau, in 25 collections, is a "sibling" in "one degree of separation" from the 316 individuals found at least once in those collections. We have begun with typological cohorts and sample corpora focused on a nodal woman (all the volumes in which her biography appears) because of the labor-intensive analysis in our project's design.

This talk introduces the cohort of travel writers in CBW, focusing on the sample corpus of volumes that include a short biography of the famous mother and travel writer Frances Trollope (CBW includes 10 books entirely of female travelers; 17 collections of great mothers or mothers of the great. It should be noted that CBW assigns 137 collection types– e.g. genre; theme; types of women in them– and the 1272 volumes may each be assigned more than one type). Her biography joins assortments of different types:



One exemplary text for this paper will be Una Pope-Hennessy's Three Englishwomen in America (London: Benn, 1929), on Frances Trollope (for an earlier account of Frances Trollope as travel writer and mother, see Booth, 2015), Harriet Martineau, and Fanny Kemble, to illustrate the concept of documentary social networks and the "siblings" who occupy a single volume. More recently, we study the author of such a collection, in the cohort of some 995 "presenters" (i.e. biographers, illustrators, editors), 567 of whom were female. Currently, the CBW database relates an author such as Pope-Hennessy only to the book, not to the persons associated with its chapters. We would like to visualize the relations among authors and their subjects as well as we already trace intertextual exchange among versions of the same lives.

DAME UNA POPE-HENNESSY
THREE
ENGLISH WOMEN IN
AMERICA
Fanny Trollope Fanny Kemble Harriet Martineau

Kemble, Trollope, Martineau, circa 1830s (Jameson, 1844)

Figures 1,2. Kemble: Steel engraving by Johnson Wilson, & Co., after painting by Alonzo Chappel, after painting by Sir Thomas Lawrence. Trollope: Frontispiece: "Francis Trollope from a portrait painted by A. Hervieu," in Frances Eleanor Trollope, Frances Trollope: Her Life and Literary Work from George III. to Victoria, 2 vols. (London: Bentley, 1895). Harriet Martineau by Richard Evans (National Portrait Gallery). Mrs. Anna Brownell Jameson, 1844, Hill and Adamson salt print, Art Institute of Chicago.

The portraits of British women authors who wrote famous observations on America in the 1830s, adapted as frontispieces, take on a family resemblance in spite of the great social and personal distance among these mutual acquaintances. Covers and illustrations often create composite portraits (see Booth, 2004:33–42) Pope-Hennessy's Englishwomen had bestselling books or tours in the 1830s, warranting their then-fashionable portraits (Cecil Beaton photographed Pope-Hennessy). Whereas Trollope and Kemble, and Martineau and Kemble, only coincide in Three Englishwomen in America, Martineau and Trollope share 8 collections, 3 on travelers, others on more miscellaneous achievement. What common ground justifies narratives of their lives in a single publication? Pope-Hennessy's title suggests it is their gendered transatlantic vision. It does not spell out that these Victorian writers attacked America for its manners and for slavery. CBW finds distinctive features in lives of women writers who traveled, besides an increase in geospatial data: a publication event characterizes and types the author ("Trollopize" is the verb the came from Trollope's offensive Domestic Manners of the Americans); literary biographies devote a high proportion of paragraphs to summary of the works, in contrast with biographies of queens or nurses, for example.

Databases tend to label persons by nationality and familial role. Our research shows the temporal or narrative dimension of supposedly fixed traits as well as the unstable scope of events. Englishness (the event "birth") should be modified by later adopted countries; Trollope and Kemble emigrated to the US for some years, and both primarily resided in Italy in later life. Married mothers, novelist Trollope and actress Kemble later separated or divorced; political theorist Martineau was unmarried and childless; these relations shape their representation. Many events challenge the researcher to affix GIS or standard dates, such as the bankruptcies (tied to family relations) that enabled all three writing careers; these crises had far-reaching continuance in creating their opportunities or need to travel. We have identified the most frequently narrated events in all versions of the three writers' lives, potentially mapping their travels, works, and lives in a way adaptable for any intertextual biographical cohort.

The talk shares portraits, visualizations of documentary social networks, maps, and innovative interface (rich-prospect browsing) to reveal analyses of versions of the same person or persons within networks of text. We sample intertextuality in which these and other women enter into the body of each others' life narratives. Like any biography, Pope-Hennessy's chapters assemble citations and redactions of previous versions, from letters, archives, and autobiographical records to biographies; the textual methods of RECIRC or a tool like Juxta, as well as BESS analysis, fruitfully compare versions. The paper will reflect on the intertextuality of representation of women writers and travelers, as well as the challenges of a comprehensive prosopographical study using digital tools to develop a large-scale and finely grained analysis of women's biographical histories.

Intertextual Networks: Theorizing and Encoding Textual Connections in Early Women's Writing

Sarah Connell and Julia Flanders

Introduction

Intertextual Networks is an initiative of the Women Writers Project (WWP) at Northeastern University aimed at exploring and theorizing the representation of intertextuality, with a focus on the citation and quotation practices of the authors represented in the WWP's digital collection, Women Writers Online (WWO). The WWP's work on Intertextual Networks incorporates several strands: focused projects conducted by individual research collaborators; sustained examination of the modalities of intertextuality as revealed by the work of our staff and collaborators; and a large-scale encoding project creating a bibliography of all the texts named or quoted in WWO, linking the texts in that bibliography with their occurrences in the WWO corpus, and substantially expanding the encoding of intertextual phenomena in our textbase. In this paper, we will discuss the aims and methods of the project, offering models for encoding complex intertextual features and setting out some processes for the systematic application of additional markup to an existing corpus. We will also consider the implications of this project for the larger ecology of digitized collections focused on gender and on women's writing.

Contexts

While Intertextual Networks is a recent initiative of the WWP, it has grown out of several decades of previous research as manifested in WWO and other WWP publications–particularly *Women Writers in Review*, a collection of around 700 reviews and publication notices responding to the authors in WWO. The almost 400 texts published in Women Writers Online are primarily print English-language works, representing a broad cross-section of texts written and translated by women from 1526 to 1850. These texts have been transcribed and encoded using the Text Encoding Initiative (TEI) Guidelines. Intertextual Networks also builds on and contributes to ongoing research into the digital representation of intertextuality, including the substantial work already evident in the TEI Guidelines' recommendations for encoding titles, quotations, and other textual references. Additionally, we are working with the Orlando Project's (see also, Brown et al, 2004) and the RECIRC project's (The Reception and Circulation of Early Modern Women's Writing, 1550–1700) bodies of research into developing taxonomies of reception, circulation, and intertextuality. Intertextual Networks is equally grounded in literary and historical scholarship on the ways that women from the early modern period to the mid-nineteenth century read and responded to texts (e.g., Horrocks, 2008; Rumbold, 2006; Winterer, 2008).

Design and goals

This project is working to create a much clearer and more textured picture of the rhetoric of intertextuality:

what female authors read; what they felt it important to quote, paraphrase, or cite; and what mechanisms connect their writing to that of other authors. In addition to the relatively straightforward instances of explicit quotations, citations, and references to specific titles, the project is also invested in developing practices for marking up subtler forms of intertextual engagement that emerge from verbal echoes, stylistic or topic similarities, imitation, parody, and other transformative ways of responding to what one has read.

Because WWO is chronologically broad and generically diverse, it provides a considerable range of opportunities to test different encoding practices against textual exemplars. The textual references in WWO are often densely layered and quite complex—for just a few examples, Lady Eleanor Davies inserts the full text of other documents into some of her political pamphlets; the 1706 Ladies' Diary constructs short poems, called "Enigmas," out of lines from several other poetic works; and Elizabeth Craven's 1789 A Journey through the Crimea to Constantinople inserts a poem that she wrote based on, and sometimes "literally translated" from a pamphlet, with citations to the pamphlet itself (43). Thus, an important goal of this project is not only to reveal early women's intertextual practices but also to test and model methods for representing the considerable complexity of these practices in TEI markup, working with formal categories without flattening out useful levels of nuance.

Encoding and bibliographic development

In developing a bibliography for the texts named in WWO, we have found that a balance of programmatic intervention and human attention can effectively accomplish systematic adjustments across our corpus. Using XQuery, we have generated a spreadsheet with the distinct titles—and authorship details where they are available—referenced in WWO. The WWP's encoding staff has been gathering basic publication details (standardized titles, authors, and dates and locations of initial publication), removing duplicates, disambiguating wherever necessary—such as with the many texts that are titled "Poems"—and adding unique identifiers. Our bibliographic data follow Functional Requirements for Bibliographic Records (FRBR) recommendations. Preserving the titles as they are represented in WWO, with the XPaths used to locate each, means that we can automatically add the unique identifiers back into the corpus when we have completed the initial bibliographic work. This approach enables us to identify the more than 6,000 <title> elements in WWO relatively quickly, while ensuring from the outset that there are no duplicate entries and laying the groundwork for the future additions of texts and textual details as we expand our source identification to quotations and other textual references.

We have also found that human and programmatic intervention can be fruitfully combined in establishing and implementing methods for encoding those intertextual features that are not straightforward <quote>s and <title>s and in expanding our understanding of how quotations and titles are being used by the authors in WWO. XPath and XQuery can reveal usage patterns and identify cases that might warrant additional investigation—such as the relatively rare instances in which titles are named in dramatic verse. Corpus-wide queries are also useful in locating additional examples of textual phenomena in order to decide how best to encode them. For example, we have reviewed emendations and translations of quotations, indirect references to titles, instances in which textual materials are elided from quotations, quotations within quotations, and incorrect or partially correct citations to develop consistent encoding practices that are applicable across our corpus, despite its variety.

Conclusion

This project is concerned with both discovering textual reverberation (the traces of women's reading that emerge in their writing) and with making that reverberation legible within the new digital systems of textual circulation. Within the boundaries of the Women Writers Project, that legibility is effected through the encoding that makes intertextuality an explicit feature of our modeling of texts. The use of a community standard like the TEI and the future availability of an API to the project's data extend that legibility—in principle—beyond the project's walls, but these methods do not in themselves build the complex web of interconnections that would constitute digital intertextuality. By placing the WWP's work alongside that of Collective Biographies of Women and RECIRC (two out of a much wider field of relevant connections) this panel will suggest what that larger intertextuality could look like, and what further work would be needed to realize it.

Digital Representation, Intertextual Relationships, and the Impact of Early Modern Women's Writing

Marie-Louise Coolahan and David Kelly

This paper emerges from the research of the team working on the RECIRC project (The Reception and Circulation of Early Modern Women's Writing, 1550–1700), funded by the European Research Council (2014–2019) and led by Marie-Louise Coolahan. It will describe the project, its development of digital tools, collaborations, and plans for interoperability with cognate projects. It will focus in particular on our development of taxonomies of reception and circulation, designed to capture data that reflects early modern source material, as the basis for our dialogue with the Women Writers Project and Collective Biographies of Women project – a dialogue that is centrally concerned with questions of intertextuality, circulation and the collaborative generation of digital standards.

The RECIRC project is essentially a study of intellectual impact. Its fundamental research questions include: Which women were read? How, where, and by whom were they read? RECIRC is structured around four interlinking 'work packages', each of which takes a specific entry point in order to amass quantitative data relating to the reception and circulation of women's writing between 1550 and 1700. The first of these posits the Catholic religious orders as transnational channels by which devotional and polemical texts were translated and transmitted; it investigates the martyrologies and bibliographies of the various religious orders, as large-scale compendia of texts that included female-authored works. The second 'work package' examines scientific correspondence networks (and therefore also complements the research currently brought under the umbrella of Women's/Early Modern Letters Online (EMLO, WEMLO) and Reassembling the Republic of Letters (led by Howard Hotson); the wealth of data to be found in the scriptorium operated through Samuel Hartlib has meant we have focused specifically on this circle. The third approach aims to rebalance the bias of digitization projects toward print culture by harvesting data from early modern manuscripts. It does so by focusing solely on the category of the manuscript miscellany (a compilation of miscellaneous materials) in order to assess the contexts for excerpting and transcribing women's writing. It differs from the Folger Shakespeare Library's Early Modern Manuscripts Online (EMMO) initiative, which is a full-text transcription project, in its harvesting and structuring of data relating specifically to reception and circulation. The fourth RECIRC approach is concerned with early modern library catalogues; it captures data on the proportion of female-authored items in order to facilitate statistical analysis relating to the gendering of such book collections.

RECIRC, then, is testing these methodological approaches for understanding the 'big picture' of textual transmission, reception and circulation of women's writing in the sixteenth and seventeenth centuries. The focus on women's writing enables investigation of the routes to impact that were exploited by early modern women, as well as of the ways gender inflected the construction of writerly reputation. It also delimits the corpus, facilitating our testing of methodologies for studying the circulation of non-elite, non-canonical writing in the period. Rather than producing a full-text digitization of primary materials, the project has been centrally concerned with developing taxonomies of reception and circulation – and these are the basis of collaboration with the WWP's current Intertextual Networks project and the Collective Biographies of Women project. This encompasses productive conversations around the kinds of intertextuality (quotation, excepting, citation of text and/or author) that occur in relation to women's writing, and their modes of digital representation. There are also important areas of divergence: RECIRC is working with metadata categories rather than xml tags; although each instance of reception evidence is supplied as full-text, these instances are themselves extracts from significantly larger texts. Moreover, RECIRC is concerned with all – women's and men's – reception of female authors, which allows for equally productive conversations about gender and reception.

RECIRC data are stored in an online database, which will be made publicly accessible at the project's close, and is intended to be interoperable with cognate projects, such as the NEWW Women Writers Virtual Research Environment. The database architecture (built using a RESTful API approach) enables multiple output formats and we will discuss possibilities for interoperable outputs. Moreover, the project is now (October 2016) at the stage of data cleaning, in preparation for experimenting with visualization tools and quantitative analysis. We aim to create network visualizations and analyses that embrace both the gendering of reception and the relationships of texts with each other. Questions include: Which genres of female-authored texts were most popularly circulated? What forms of circulation (translation, excerpts, citation) were most conducive to their transmission? How important (and prevalent) was attribution to their circulation? Which female authors were reading and using other women writers? What circulation contexts promoted women as authors? If accepted to DH2017, we intend to present our preliminary answers to the questions and patterns that emerge during this quantitative analysis phase.

Abstract

In an essay exploring the possibilities of "critical infrastructure studies," Alan Liu calls upon scholars to "'see through' the supposed rationality of organizations and their supporting infrastructures to the fact that they are indeed social institutions with all the irrationality that implies." This panel brings together three librarians from different institutional contexts to interrogate DH infrastructure as a primarily social -- and irrational -- formation. If DH infrastructure is "only" what we make of it, how do we consciously, actively shape DH infrastructure to support what DH could be? How do the social formations of DH infrastructure activate -- but also potentially inhibit -- access by scholars, students, and publics? How do certain social formations of institutional DH mask the emotional labor of DH professionals supporting the work of other researchers? And finally, what is the relationship between infrastructure and underlying institutional culture? Can a critically engaged infrastructure overcome or repair a culture that may undermine the values that we want to instill?

Laura Braunstein will explore the challenges of sustaining DH infrastructure without a DH center. Project management, collaboration, outreach, and digital pedagogy take an ad-hoc and at times, rogue presence, connected only by virtual infrastructure. A DH community of practice that exists primarily as a social network can enable serendipitous connections, but it is not sustainable, for scholars, teams, or projects. How can we institutionalize a virtual DH non-center in order to support activities and projects without inhibiting its energy and possibility?

Thomas Padilla will explore assumptions latent in prevailing notions of scalability in the Digital Humanities. The need to qualify DH infrastructure development, web-based projects, and data sources by the extent to which they are scalable or not tends have the effect of either totally disincentivizing participation by cultural heritage organizations or incentivizing in a manner that tends to occlude acts of individual agency and creation. How can we work to develop practices and methods for exposing and according value to a wide range of cultural heritage work? In what ways does exposing agency and according value to intellectual and physical labor a necessary predicate of research integrity in DH?

Amanda Visconti will explore how we might align DH resource investment with explicit personal and intellectual values such as inclusion and open access. Multiple DH centers already define the scope of the DH they support not through some over-generalization (e.g. "we support innovation in humanities via digital scholarship"), but instead through charters envisioning and encouraging a DH that performs what we care about. How do we use the wiggle room at our disposal, small or large, to push our institutions toward supporting a better DH? How can we act on our values through policies that center resources on work strengthening these values?

Panel organization

As the discussion is informed by each speaker's local context, each of the three speakers will give a 5-minute introduction of their background and interests (15 minutes total). Each speaker will then interview the other two speakers with a prepared question (2 questions from each speaker, 6 questions total at 5 minutes each, 30 minutes total). At the last part of the panel, we'll open up the discussion for both Q&A and audience sharing; the panelists will moderate the conversation so that everyone gets a chance to contribute.

The speakers are:

- Laura Braunstein, Digital Humanities Librarian, Dartmouth College

- Thomas Padilla, Humanities Data Curator, University of California Santa Barbara
- Amanda Visconti, Managing Director, Scholars' Lab, University of Virginia Library

Treating a Genre as a Database: the Chinese Local Gazetteers, the LG Tools, and Research Based on This New Digital Methodology

This panel discusses how digitization and digital tools help to bring new insights to a well studied genre, in this case the Chinese Local Gazetteers, by supporting research inquiries that treat the whole genre as a conceptual "database" to answer especially large scale questions that take into account gazetteers from multiple geographic regions and within long time spans.

The Chinese Local Gazetteers is a long established genre of writing in China since the twelve century for recording local knowledge about a region. Local gentry and officials compiled information about a region, ranging from landscape, flora and fauna, officials and celebrities to temples and schools, local culture and customs, and taxes and census, and kept them in this genre. Despite that Local Gazetteers have been major sources for scholars to find specific information about a place, it turns out to be very difficult if a scholar wishes to study the gazetteers on larger scales due to the vast amount of information contained within. Thanks to the increasing recognition of digitizing historical sources, as of 2016 nearly half of the extant 8,000 titles of local gazetteers (one title can mean one to dozens of physical volumes) has been digitized as searchable full texts and provided access through various databases from public and private sectors. However, despite of the large amount of local gazetteers available electronically, these databases mainly provide features that replicate how physical books are used: users are able to flip a gazetteer page by page; even when reading the returns from a full text search, a scholar still needs to click the returns one by one in order to read the texts. Such principle of treating the gazetteers individually highly restricts the possibility of researching large sets of digital gazetteers. Historians need better tools to work with the large amount of digitized gazetteers to employ new forms of digital research methodologies and to fully benefit from the digital formats. One important methodology that we address here is the possibility to treat the whole genre as the body of inquiry in order to research global and large scale phenomena that are across individual gazetteers, geographical regions, and time spans.

Under this context, Department III “Artefacts, Actions, and Knowledge” of the Max Planck Institute for the History of Science (MPIWG) embarks on a digital project to build digital tools specifically for this genre that allow scholars to adopt this methodology of treating the available set of digitized gazetteers as a conceptual “database” to post inquiries. The digital tools, which we call **the LG Tools**, include a full text search facility, an Extraction Interface to collect data in the form of lists, a research repository to store and publish collected data, and an interactive mapping and analysis platform that are linked to data collected via full text search or the Extraction Interface in order to visualize the data geographically. We have presented the LG Tools last year in this conference. The abstract, which contains detailed description for the tools, can be found online.

In this panel, we would like to shift the focus from the tools themselves to the types of research that can be derived from the LG Tools and from the methodology of treating the whole genre as a database. We invite four scholars in Chinese history to demonstrate their research projects and to discuss what advancement the LG Tools have brought to their research. The topics of their research range from history of science and technology, environmental history, to social and intellectual histories. The four historians and their research projects are described below.

Qun Che

Qun Che uses the LG Tools to trace the transformation of the geographic landform of the Dongting Lake, a flood basin of the Yangtze River, by looking at the construction of “Yuan” recorded in the local gazetteers during the Ming and Qing dynasties (1368-1911). Yuan is a type of water conservancy that literally refers to fields surrounded by embankments to prevent river flooding. Che first finds all the occurrences of Yuan constructions in the available digital set of local gazetteers by full text search. The resulting dataset is then sent to LGMap, the interactive mapping and analysis interface among LG Tools. By using LGMap, Che is able to clarify the Yuan constructions in the Dongting Lake region in different time periods and by doing so to trace the flooding and deposition process of the lake to understand how the lake has been shaped from the past to today. Figure 1 shows the LGMap interface for analyzing the periods and locations of the Yuan constructions near the lake.

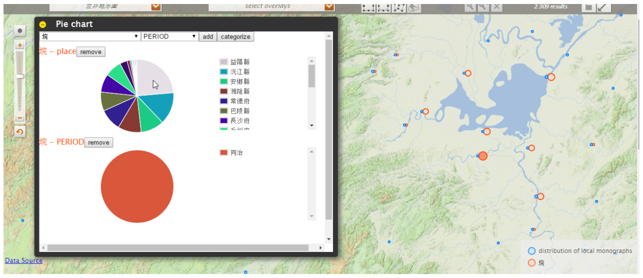

Figure 1. Yuan constructions recorded in the available digital set of Local Gazetteers, visualized in LGMap

Ling Cao

Ling Cao collects records in the local gazetteers describing the growing and spreading of maize in China during the Ming and Qing dynasties in order to understand through which geographical routes maize was introduced to and spread in China. She further relates the regions of maize growing and their scales to the occurrence rate of natural disasters of the typical maize regions to see the influence of maize over the ecological environment. From the records she collects, Cao is able to raise the hypothesis that the introduction and growing of maize in the mountain areas might cause the destruction of forests and result in serious soil erosion which in turn led to blockage in downstream rivers and floods.

Dagmar Schäfer

Dagmar Schäfer researches on the relationship between material availability and the development of local knowledge organization in the local gazetteers. While not all local gazetteers share the same classification schemes or even topic, local officials recorded local expertise and material specialties in the gazetteers. In which sections did local gazetteer compilers place such information? When and how did their descriptions vary (such as details, terminology, etc.)? The full text function of the LG Tools and the section titles that MPIWG invested to type up give hints on the above questions. The contribution also aims at discussing the possibility of tracing and analyzing networks of materials: how did officials relate materials to another; can scholars identify clusters among the materials. The contribution also posts questions on how social network analysis can be applied and what are the advantages of geographical mapping.

Hongsu Wang

Hongsu Wang will demonstrate how the LG Tools especially the Extraction Interface helps the China Biographical Database project (CBDB) to collect data about local officials from local gazetteers. CBDB is a freely accessible relational database with biographical information about more than 360,000 individuals in historical China. In addition to the large dataset, CBDB embeds functions to analyze the individuals via statistical, social network, and spatial analysis. CBDB turned to local gazetteers when it tried to increase its collection on individuals that were mainly based on central government records. The individuals listed in the sections of "local officials" in most gazetteers are ideal for this purpose since most of them don't appear in imperial government records. By using the Extraction Interface, which provides a regular expressions editor to help capture regularly written information such as lists, student assistants at CBDB were able to collect 250,000 officials from 291 local gazetteers using just 420 man-hours.

Organization of the panel

This panel will include five speakers. To give the audience a background for discussion, Shih-Pei Chen (MPIWG) will begin by giving an introduction to the genre of Chinese Local Gazetteers and its characteristics as well as the LG Tools (15 minutes). Then, the other four panelists will each present their research projects and show how they get new findings through using the LG Tools (each speaker 10-12 minutes). We will then have a discussion session (roughly 30 minutes) for the panelists to talk about how the existence of the LG Tools has changed the objects of study and/or the approach to these objects and to discuss the conceptual frameworks and assumptions challenged by the use of digitized sources. We will also address the point of how the LG Tools help the panelists to develop the idea of a regarding the genre as a "conceptual database". The audience is invited to join in the discussion session for conversations on the types of advancement these tools bring to the study of history and humanities, whether similar tools can be set up for digital resources in other humanities disciplines, and the copyright issues encountered for building such tools.

Challenges for New Infrastructures and Paradigms in DH Curricular Program Development

Introduction

Many leading universities in the United States have recognized the profoundly transformative effect that DH has had on research and teaching and have established lab-based research programs or institutional centers for interdisciplinary collaboration on digital projects in the humanities. The University of Virginia led with the Institute for Advanced Technology in the Humanities, which now supports more than forty DH research projects. The Stanford Humanities Laboratory, established in 2001, is a collaborative research environment for cross-disciplinary and multi-institutional, technologically transformative projects. Duke, a founding member of HASTAC (Humanities, Arts, Science, and Technology Advanced Collaboratory), adopted a similar model within its John Hope Franklin Humanities Institute. Other universities such as Harvard, Brown, Dartmouth, Berkeley, Princeton, and the University of Michigan have begun aggressively to hire in the field and to design multidisciplinary DH programs. Moreover, University of Pennsylvania and Yale have attracted large donations from alumnae for DH institutes, while state institutions like Maryland, Nebraska, and UCLA have garnered millions of dollars in external funds to support their field-leading digital scholarship centers.

Digital Humanities scholarship is, by necessity, collaborative and interdisciplinary. DH approaches to the creation and dissemination of scholarship investigate the information life cycle from digitization to preservation including multimediality, design elements, and computational reasoning and implementation through perspectives developed in the context of deep understandings of the key issues at stake in the humanities. DH approaches to teaching typically involve an emphasis on experiential learning and research by creatively expanding modes of access and networks of participation through the methods that students employ. This multidisciplinary work in research and teaching is not limited to conventional humanities departments, but, rather, emerges in every humanistic field, in arts and architecture, information studies, film and media studies, archaeology, geography, ethnic studies, and the social sciences. Because of this essentially multidisciplinary nature of DH work, some of the universities listed above have begun to move away from more traditional models of DH where DH is housed in the library or where DH is primarily an endeavor of the English or History Department. Northeastern University's center for Digital Humanities and Computational Social Science (NULab) and King's College DH Department, for example, bridge the humanities and computational, qualitative social sciences while Bard College's Experimental Humanities Concentration and Initiative is focused primarily on the arts.

Even with all this funding and enthusiasm, however, it remains surprisingly challenging to design curricula in DH on the undergraduate and graduate level. These challenges are a direct result of the fact that attempts to develop new paradigms and models for "training" students break (or stretch) molds for learning and teaching that have calcified over decades into departmental silos and administrative policies concerning credits and teaching loads. These challenges include the difficulty of organizing teaching arrangements that include faculty from multiple disciplines, supporting cluster hires versus supporting "reskilling" faculty to teach new methods from different perspectives, and designing single courses with heavy loads of material including perspectives on the world (such as cultural critique) alongside advanced topics in, for example, statistical models, computational approaches, and data visualization.

This panel will include representatives from five programs who bring perspectives from both private and public, large research universities and small liberal arts colleges in the United States. The panelists have worked within the context of long-standing digital humanities centers as well as within initiatives just now developing without these historical, infrastructural legacies. Each panelist will speak for twelve to fifteen minutes on the below topics, leaving time for questions from and conversations with the audience.

Tanya Clement

For many years, Digital Humanities at the University of Texas at Austin has happened on a project-level basis, without the support of a DH center, in American Studies, Anthropology, Classics, English, French and Italian, History, Information Studies, and in Portuguese and Spanish, among other departments (some projects can be viewed at the UT DH page)

At UT, we are experiencing a scenario that is familiar at universities and colleges that are supported by instantiated DH centers and initiatives. The existing, funded projects at UT do not offer enough project-based, training opportunities for a wide range of students. Project-based work with digital information technologies is often heralded as the site of work that defines DH (Burdick, et. al, 2012; Drucker, 2012; Hayles, 2012; Svensson, 2009, 2012). It is also the site of experiential learning and project-based research in DH on the undergraduate and graduate level, a trend that is noticeable in many of the lessons and curricula collected in the recent Modern Language Association publication, *Digital Pedagogy in the Humanities: Concepts, Models, and Experiments.* Even with this fabulous array of DH classroom-based assignments, the students who are best trained in DH -- those who on the graduate level are best prepared for the job market in private and public industry as well as the academy -- remain those students who participate in the kinds of long-term, interdisciplinary-team-led projects that have become the mainstay of DH. These kinds of projects, however, usually only have the funding to train a handful of lucky students. At UT, we are working to consider a different paradigm for teaching and training students that is not dependent, primarily, on the soft-money world that remains the status quo for most underfunded DH projects.

To better understand our proposed methods of training, it is important to describe the UT landscape. The University of Texas at Austin is a large research university with over 3,000 teaching faculty and over 50,000 students. It is rich in multicultural, multimedia, obscure and popular special collections of interest to humanities scholars. Some examples include the Gloria Anzaldúa archives, the Guatemalan National Police Historical Archive (AHPN), and the Radio Venceremos collection of digital audio recordings of guerrilla radio from the civil war in El Salvador housed in the Benson Latin American Collection. The papers of Carson McCullers, David Foster Wallace, and Gabriel Garcia Marquez as well as many collections of medieval and early modern manuscripts including one of five copies of the Gutenberg Bible in the United States are at the Harry Ransom Center, which also holds a robust collection of film (including the archive of Robert Dinero), photographs (such as the Magnum Photos' New York bureau collection, dating from 1929 to 2004), and authors' recordings including tapes of Anne Sexton's therapy sessions and Spalding Gray's performances alongside the center's other robust collections of twentieth century writers and performing artists. At the Briscoe Center for American History there is the Texas Poster Art Collection which documents the visuals behind the pivotal early music careers (1960s to 1970s) of iconic music legends such as Willie Nelson and Townes Van Zandt as well as over 2000 reels of tape that include the field recordings of folklorists John A. Lomax, William A. Owens, Américo Paredes, and John Henry Faulk.

The list of amazing collections at UT goes on, but in terms of DH, it doesn't matter. Most of these materials, like most of the materials (no matter if they are paper, reels, tape, or photographs) in special collections at many institutions are almost completely inaccessible to DH methods of presentation and inquiry – *even when they are digitized*. These materials are either under copyright; in non-text formats such as an image, audio, or video file; undescribed (and therefore, in many cases, undiscoverable); or unstructured; all of which make them unsuitable for most DH tools. Instead, UT scholars and teachers, like scholars and teachers everywhere, typically use the same collections that others use: what is freely available online – a trend that systematically limits the kinds of questions we can ask in DH scholarship and teaching.

At UT, we are trying to address these issues in our plans to create an undergraduate and graduate curriculum in DH by considering three primary questions that plague DH curriculum development everywhere:

1. How do we train a wide range of students on the undergraduate and graduate levels across a wide range of DH issues including, but not limited to, the creation of digital collections and archives; the analysis of digital materials; and the use of digital technologies to write, publish, and consume scholarship when our faculty are siloed from each other not only by administrative departments but by their, sometimes, many decades of differing experiences and training?
2. How do we teach students to consider multimedia and multiculturalism when using DH methods when the primary materials to which we have "data ready" access are text-based, in English, and unstructured?
3. How do we create an interdisciplinary framework that is productive and innovative as well as sustainable?

Building on the amazing work done by DH scholars in praxis-based training programs in libraries such as the Scholars Lab at the University of Virginia, Columbia's Developing Librarian Project, and Indiana University's Research Now: Cross Training for Digital Scholarship initiative, the DH@UT initiative is imagining a sustainable model for training students that is experiential, collaborative, and interdisciplinary. Collections are at the heart of humanities research. The work to make such collections "data ready" for DH scholarship coincides with deep expertise in the humanities as it relates to the organization, preservation, curation, analysis, visualization, and communication of digital works in the humanities. Pairing students with projects for making the collections at UT more accessible offers a unique opportunity to train students to generate a more diverse range of data-ready collections and to immerse them in questions surrounding critical information infrastructure studies (Clement, 2015; Liu 2016; Verhoeven 2016) that has engaged staff, undergraduates, graduates, and faculty at the heart of DH research.

Questions remain, however, about how such a program could be implemented. Faculty from a variety of disciplines will have to commit to using UT collections that perhaps do not fit exactly into their research objectives. The time commitments of library and archives staff, who are already often overwhelmed and under resourced, will need to be committed to the goals of the program; and, policies concerning how and when archival materials can cross the transom of the brick-and-mortar collection building (both physically and virtually due to copyright and privacy restrictions) will have to be reconsidered. There is reason to believe that faculty, used to "stretching" their area of expertise to teach classes, would be willing to commit their considerable effort in teaching classes in these new directions. There is equal reason to believe that staff members, committed to the goals of the institution to make their collections more accessible will also be in favor of such a program. Yet, in order to make this program sustainable, both faculty and staff will need support from upper administration. Commitment at the university level for innovative teaching and research remains imperative for changing the praxis of pedagogy. This talk will discuss our progress in these endeavors.

Alison Booth

Technological literacy is a stated educational goal for all students at the University of Virginia, and various existing groups in the Library and schools such as Arts and Sciences support teaching with technology and short assignments in courses (maps; e-portfolios, etc.; Learning Design Technology). But many would agree that digital humanities is something distinct from teaching with technology; there is more to be gained from student participation in open-ended projects (exceeding the timeframe of a single assignment) that reflect upon their tools and methods as well as on the specific data of a discipline. Considerable international discussion of DH pedagogy has advanced the field (Digital Pedagogy), and several textbooks serve courses that introduce students to DH (e.g. Gold and Klein). Certificates in DH (e.g. at Northeastern University and University of Maryland) provide models, as do departments of Digital Humanities (as at King's College, London). CenterNet presents a directory of DH centers on every continent, some like UCLA's Center for Digital Humanities offering a program with an undergraduate minor and graduate certificate.

What are the best models? How should we build an infrastructure for DH education at the University of Virginia, based on what we already have? The University of Virginia has longstanding centers practicing DH: the Institute for Advanced Technology in the Humanities, SHANTI, Scholars' Lab. Advanced research projects and courses or workshops in methods and tools are supported as well in Research Data Services, Data Sciences Institute, Makerspaces in arts, architecture, and engineering, among others. And yet the curricular offerings in DH have remained dispersed among a few academic departments and the Scholars' Lab's Praxis Program and fellowships, along with some digital fellowships for undergraduates working in art and archeology. I suggest a model: the Pedagogical Pyramid, which can be multiplied within one or many institutions in communities of interaction.

Is a Pedagogical Pyramid a menacing structure, an image of hierarchy and exploitative labor? Instead, it is intended as a metaphor and visualization (equilateral triangle in multiple dimensions) of a *graduated* structure of collaborations, potentially across institutions as well as UVA schools, on advanced research in the humanities, arts, and social sciences: more undergraduates, fewer graduate students, and fewer faculty. The numbers, limited only by practicable scales of collaboration, are flexible, but based on likely proportion of an institution's personnel in these ranks. The paid internships, fellowships, and mentorships proposed in this structure would be available in smaller numbers for team members who are at later career stages, but there will be no idle supervisory roles for those figuratively at the top. Participants would develop a charter in keeping with the Collaborators' Bill of Rights. With sufficient resources for faculty as well as students (stipends, wages, facilitators and spaces), we would run concurrent Pyramids.

We have developed parts of such a vision. IATH supports two residential fellows per year for two years each, with some course release and research funds. The Scholars' Lab under Bethany Nowviskie created a custom-built, annual cohort of six doctoral fellows who collaborate on a project. Praxis flourished under Purdom Lindblad and current members of Scholars' Lab, and has generated a Praxis Network connecting various institutions. Each year in addition there are 2-3 dissertation fellows in the Scholars' Lab, and we have had graduate fellows jointly in Data Sciences and Scholars' Lab. Undergraduates and graduates are employed in the Scholars' Lab Makerspace, and any students or faculty may work on any projects in that innovative research laboratory. We collaborate with a liberal arts college in Virginia, Washington & Lee, that adopted the Praxis model in its library-centered DH Studio; UVA and W&L hold exchanges among both institutions' Library staff, UVA's Praxis and DH fellows, and W&L's undergraduate students. Scholars' Lab has also led two summer programs for 4-6 Leadership Alliance Mellon Initiative (LAMI) undergraduate students from HCBUs and Puerto Rico, introducing DH and other research methods in preparation for graduate school applications. Collective Biographies of Women, an IATH and Scholars' Lab project, each year trains small groups of graduate research assistants (primarily MA) and a few paid undergraduates; LAMI students each summer have added research on African American and Latino cohorts.

Which brings us to planning the future of a DH community at UVA. Recent developments have focused on coordinating the community in a DH@UVA website and the DH@UVA 2016 conference, at which the open discussion came to a consensus on a certificate or program in DH. We do not want to build a DH department, as that may be less adaptable for future technological and curricular change.

Desirables: early introduction to digital research methods in interdisciplinary courses, workshops, and bootcamps suitable for undergraduates, graduate students, or both; engagement of undergraduates (for credit or pay) in faculty or graduate-student research projects in humanities, arts, and social sciences, beyond the classroom assignment; opportunities for graduate students to mentor and teach these undergraduates; paid graduate interns and project managers mentored by Library-affiliated faculty and staff who can work with faculty projects from many departments; different models of support for faculty digital scholarship beyond the IATH fellowships; expansion beyond the six Praxis students and 2-3 DH dissertation fellows per year that we currently support in Scholars' Lab.

Challenges for building such alliterative pyramids: persuading more faculty to participate and encourage their students in these opportunities; luring the CS faculty and students, the Data Sciences Institute, and the Library's Research Data Services group to collaborate with humanistic computational research, increasing broad interdisciplinarity; coordinating with the Graduate School and other schools to fund graduate fellowships, encourage dissertation advisors' participation, and monitor time-to-degree; securing additional resources for wages and faculty stipends as well as graduate fellowships and teaching release; negotiation with Directors of Undergraduate Studies and Graduate Studies as well as the Graduate School regarding requirements, credit courses and a certificate or program, which would have to be maneuvered through the channels of educational policy at university and state levels. Curriculum would have to be designed that allows discipline-specific units to be added to shared units on generally applicable tools, methods, and issues. The structures would have to ensure that all contributors are compensated and acknowledged, including in presentations and publications. UVA already has ample evidence of the enhancement of research and the advantages in students' learning and placement that come from the existing activities in DH groups. We look forward to giving these aims more substance and structure.

Ryan Cordell

During MLA 2013, Natalia Cecire wryly observed on Twitter, "1. DHers usually don't see dh as panacea. 2. Admins often do. 3. DHers often need for admins to have this erroneous belief." Our experiences building a graduate DH curriculum at Northeastern in many ways illustrate this rhetorical tension. We benefit from substantial administrative support for curricular ingenuity while struggling to reconcile that support with increasing disquiet in the departments that must underwrite any substantive changes we seek to make.

We are enormously fortunate at Northeastern and the NULab. Our administration has funded several years of cluster hires, which have allowed us to bring DH faculty into the English; History; and Cultures, Societies and Global Studies departments, as well as DH faculty and staff in the library. Over the course of four years we have founded a new center, integrated introductory and advanced DH courses into our curriculum, launched a DH graduate certificate program, and trained many students through work on locally- and grant-funded projects. This in turn has led to an increased number of students applying to our graduate programs seeking DH training.

This rapid, whole-cloth invention of a DH program, however, has been attended by pressures, fissures, and tensions with existing programs. For example, NULab faculty are proud of the robust coursework required for the DH certificate program: the equivalent of 3 courses out of the 10 required in our English MA program or 14 required in our English Ph.D., plus the development of a small scale DH project. Our students take not only an introductory DH course, but also advanced methods courses (data modeling, text analysis, etc.) that prepare them to integrate DH methods into their theses and compete for DH positions after graduation. Within English, however, completing this requirement requires students to decide their path almost immediately upon admission, and the decision to pursue the certificate dictates very particular paths through the larger Ph.D. program. While our DH faculty are a larger group than at most institutions, even so we cannot practically mount more than two courses per year: an introductory course each fall and an advanced course each spring. These advanced courses rotate among NULab faculty and thus have very distinct foci. Thus students' options for completing coursework remain relatively constrained over two years of full time coursework in ways that sometimes mitigate against the particular training individual's need. A student primarily interested in digital archive creation, for instance, might by necessity take their advanced course in Humanities Data Analysis rather than Data Modeling; while the latter would be more appropriate to their interests it can only be offered every three years or so, when a particular faculty member is on rotation for the advanced seminar.

These pressures are compounded for MA students in English or Public History; in the latter case we find there is really only one viable set of courses that can result in both a DH certificate and Public History credential within the timeline of the program. Due to these challenges, NULab faculty are currently reevaluating how to align our high expectations for DH training with the practical realities of a certificate program, which must exists alongside and in harmony with the primary curricular structures of humanities departments.

In addition to pressures on students, the popularity of the DH certificate among its first two cohorts of students has led to growing worry among departmental faculty that DH is driving down enrollments outside certificate program courses. We might be tempted toward market explanations ("we cannot dictate which courses students are interested in" or, less generously, "if our colleagues made their courses more enticing") but these are neither sufficient nor reflective. The NULab has created a certification that students perceive as necessary in a competitive job market, despite ambiguity about the role of DH in securing jobs (Risam 2013). Thus we have institutionalized a hierarchy of graduate course offerings that does privilege DH courses over others in the curriculum, in ways that partially reflect students' interests but partly reflect their anxieties. Moreover, the administration's vision for graduate education in the future clearly emphasizes digital humanities in ways that worry even NULab faculty. We cannot, in other words, entirely dismiss our colleagues' worries about how digital humanities, which belongs to no department in particular, has shifted the character and priorities of graduate programs in the particular departments of English and History.

In my presentation, then, I will think through what constitutes a successful DH graduate curriculum in an institutional culture of abundant top-down support and atrophying bottom-up enthusiasm. Can we structure robust DH training in ways that integrates with rather than competing with departmental training? Can a DH program be partner rather than usurper?

Miriam Posner

UCLA's Digital Humanities graduate certificate, founded in 2011, now enrolls 24 Ph.D. and master's degree students from across the university. Initially, the certificate was conceived as a means of providing an imprimatur for work that was already taking place at the graduate level. UCLA's humanities graduate students were already apprenticing on a wide range of faculty-led digital humanities projects, such as HyperCities and RomeLab, and developed a great deal of discipline-specific expertise through these experiences. The university, moreover, has a strong community of faculty DH practitioners and an established tradition of integrating graduate students into projects as collaborators. But as formal DH curricula grew at other institutions, UCLA graduate students and faculty began to feel that a formal credential might be useful to graduates as they entered the job market.

Even as students clamored for it, the introduction of an official graduate certificate has also had the effect of surfacing some challenges and dilemmas for graduate education in the digital humanities: how much of the graduate curriculum should be formal, and how much should come in the form of project work; how to provide the time- and resource-intensive instruction graduate students require; how to help students balance traditional dissertation work with digital work; how to accommodate the very distinct needs of Ph.D. students and professional master's degree students; and how to prepare graduate students for an unpredictable job market. Alexander Reid identified many of these dilemmas in a 2012 essay for *Debates in the Digital Humanities*, observing an uptick in digital humanities activity and arguing that we would soon witness a widespread shift in the education of scholars, toward an understanding of digital literacy as fundamental to graduate training (Reid 2012).

From the vantage of 2016, the picture seems less clear. Digital humanities continues to thrive as a field, but we have yet to see the searching, widespread reevaluation of graduate education that some observers expected. While a number of standout programs, such as the City University of New York's Graduate Center, the University of Virginia's Scholars' Lab, and the University of Victoria's Electronic Textual Cultures Laboratory, have seemed to forecast change on a larger scale, most humanities graduate programs still deal only gingerly, if at all, with digital technology.

The example of UCLA might help to illuminate some reasons for this very piecemeal rate of change. UCLA's graduate students, like most graduate students, are under enormous pressure and feel pulled in multiple directions by an erratic and whimsical job market. Assailed by advice to publish in top journals on the one hand, and to develop digital skills on the other, they often come to the DH program ready to perform a cost-benefit calculation about how this training will position them on the job market -- not exactly the spirit of embracing failure and creative experimentation that many DH experts advise (Ramsay 2010, Drucker 2009, Sample 2012). Devising a curriculum that makes sense for them in this climate, then, is constantly demanding and resource-intensive. Among the questions UCLA faculty has faced:

- Should a digital humanities program for graduate students emphasize collaborative scholarship, as many practitioners advise, or should students' DH work advance the individual dissertation?
- What is the program's responsibility toward preserving and archiving student digital work, and particularly digital dissertations?
- If a graduate DH program remains interdisciplinary, how can it assemble and retain the necessary core faculty to staff the program?
- How can an interdisciplinary program retain a "center of gravity" sufficient to enable graduate students to feel as though they are part of a community?
- How can a graduate DH program communicate its value to students' advisers, many of whom do not engage in digital work themselves?
- Given the highly individualized nature of dissertation-level work, how can graduate DH programs provide sufficient resources (staff time and technical assets) to help students advance their research meaningfully?
- How should a graduate program in DH balance the distinct needs of professional master's degree students (in UCLA's case, MLIS students) with Ph.D. students?

In this presentation, I will discuss the ways in which we at UCLA have attempted to develop a graduate curriculum that makes sense for a program that faces challenges familiar to most universities: lack of resources, little centralized support, and overtaxed faculty. I will also raise some questions about the sustainability of a digital humanities graduate curriculum without answering some searching and difficult questions about what a graduate program should be and do. Finally, I will propose some infrastructural and institutional solutions to help address some of the most pressing needs of graduate DH programs.

Maria Sachiko Cecire

At Bard College, we don't have a formal Digital Humanities center. Instead, we have an interdisciplinary curricular initiative and hub for faculty collaboration that we call Experimental Humanities (EH). DH scholarship at its most visible typically creates and employs digital tools to pursue project-based humanities research. While EH does some of this, our program was designed to align with the mission of our undergraduate-focused institution, and to be flexible enough to bring together faculty from diverse intellectual and personal backgrounds. We say that Experimental Humanities is Bard's liberal arts-driven answer to the Digital Humanities: it uses a network of courses and faculty-identified research clusters to variously interrogate how technology mediates what it means to be human. EH engages with media and technology forms from across historical periods, including our own, and combines experimental research methods with critical thinking about way media and technology function as a part of cultural, social, and political inquiry. We encourage the reconsideration of older media in light of today's technologies, and look ahead to the developments on the horizon.

The decision to name our program Experimental Humanities instead of Digital Humanities was grounded in the unique character and history of Bard College, which has developed an international reputation for its commitment to the arts, humanities, and the notion that access to a liberal arts education should be a fundamental human right. Although our primary campus in the Hudson Valley of New York serves just over 2000 students, Bard has a much wider reach that includes degree-granting programs in state prisons, early college programs at high schools that serve low-income youth in cities around the U.S., and in international university partnerships that bring liberal arts curricula to countries such as Kyrgyzstan, Palestine, and Russia. In this context of passionate liberal arts advocacy, we wanted a title that would leave room for DH but not exclude non-digital forms of artistic and scholarly production. As Wendy Chun has suggested, terminology that draws hard lines between "old" and "new" technologies runs the risk of excluding (or at least seeming to exclude) the lessons, theories, and knowledge of the past from the practice and study of "new" media. The notion of the "experimental" embraces both digitality and previous moments of technological change, invokes the practices of both the sciences and the arts, and has the kind of hands-on and countercultural associations that align with the Bard ethos.

We saw the rise of DH as an exciting opportunity to establish a program dedicated to reconsidering the methods and subjects of humanistic study in the light of changing material conditions. This is an ongoing project, and one that also allows us to continuously re-evaluate our pedagogical approaches: rethinking which tools and methods we use in the classroom and encouraging in-class reflection with our students about the relationships between who we are, what we study, and how we study it. For instance, when faced with N. Katherine Hayles's work on hyper and deep attention, students may put forward arguments for practicing deep attention in their coursework or advocate for a pedagogy that introduces more multimediated and hands-on content, thereby creating the opportunity for jointly designed assignments. Finally, in keeping with the concerns raised by #transformdh (see, for instance, Moya Z. Bailey's essay "All the Digital Humanists Are White, All the Nerds Are Men, but Some of Us Are Brave") we wanted to keep cultural critique and questions of inclusion central to what we do as humanities scholars.

With these ideals in mind, we set out to design a program that would be critical, inclusive, undergraduate-focused, and also able to participate in wider DH networks. In their essay about whether or how small liberal arts colleges might "do" DH, Bryan Alexander and Rebecca Frost Davis outline several challenges to establishing DH programs and centers at institutions like Bard. They note a lack of infrastructure to support major research projects, the difficulty of pulling together the human resources to do work that requires a wide range of skills, our limited access to graduate students that can sustain long-term research, and the pedagogical focus at SLACs. However, they argue that models that include curricular elements and partner with existing campus resources like library and IT can still be successful, developing proficiency in select project areas and sending students on to DH graduate programs.

Experimental Humanities does work closely with Library/IT and encourage faculty projects through training opportunities, the guidance of a Digital Projects Coordinator with a PhD in the humanities, and the support of a student Media Corps. But while several successful DH programs at other small liberal arts colleges have grown out of the library, like Occidental's Center for Digital Liberal Arts, or out of faculty research, as with Hamilton's Digital Humanities Initiative, EH was from its first imaginings a primarily curricular initiative, built on the three pillars of history, theory, and practice. All EH students take the core courses "A History of Experimentation" and "Introduction to Media," which EH faculty rotate teaching, and at least one practice-based course beyond the college arts requirement (this may include Computer Science or one of the visual, written, or performing arts). Students also take at least two more courses from the wide offering of EH-listed courses designed by faculty according to their research interests, and which are available each semester in fields from Music and Anthropology to Medieval Studies and Theater. These classes present the hands-on projects and research that they do at collective Share Events each semester.

At an administrative level, EH is a concentration (like a minor; Bard loves to have its own terminology for everything), which means that our students pair their coursework with a foundation in a major program of study, and that EH faculty also belong to a home program. All Bard students do yearlong senior projects, which allow our students to bring what they have learned in the concentration into conversation with their major discipline in a capstone project. We have seen senior projects that use topic modeling to analyze slave narratives, develop gaming apps with the potential to treat psychopathy, push the boundaries of traditional interview-based ethnography to consider the social implications of conversing via text message, delve into the history of the book and other media forms, and lead to immersive art installations in both digital and analog formats. Our students do not necessarily go into DH programs (though some do), but rather become curators, teachers, librarians, programmers, artists, and work for non-profits.

This kind of breadth makes Experimental Humanities sustainable even on a small campus, providing a hub for a range of interests and methods. Meanwhile, our regular course and event offerings give the program continuity and create opportunities for faculty and students to meet during the semester as a self-identifying community. We have also worked to bolster faculty research in recent years, beginning with the launch of our faculty-led, topic-based clusters in 2014. The clusters have been very successful in bringing faculty together to share and further their own research across disciplinary boundaries, and have yielded a number of new courses and given rise to a form of experimental symposia that bring together scholars, artists, practitioners, students, and community members around cluster topics such as "Sound" and "Surveillance." The clusters have become a model in the college for how to foster interdisciplinary collaboration that encourages both new research and student engagement. Other research models in EH include faculty-led humanities labs around individual projects, intensive student sessions with historical societies to create digital repositories and interfaces for the public to access its local history, and courses with embedded digital projects that allow faculty to work with undergraduates to build up layers of data each time that they teach the course.

EH is now in its fifth year, and coming to the end of a three-year grant from the Mellon Foundation. In my presentation I will discuss several of the challenges that we face at this crucial stage of transition. These include the ongoing struggle to define what we do and why it's useful to students, parents, and future employers, given our capacious title and mission; how to practically negotiate the need for disciplinary foundations in our students' and faculty's home programs and the invitation to experiment in EH courses and projects; how to move off of a major grant to become sustainable within the existing college structure (and thereby resist the kind of dependence on external grants that is contributing to the neoliberalization of the humanities, as outlined in the widely circulated "Dark Side of the Digital Humanities" papers); and how to better integrate the wider Bard network of underserved high school and undergraduate students both in the US and around the world into the work that we do.

Introduction

Scholarly discourse evaluating the digital turn in biblical and religious studies is at an early stage in its development, as attested to by the creation of two new book series in 2016: *Introduction to Digital Humanities: Religion* (IDH, de Gruyter), and *Digital Biblical Studies* (DBS, Brill). Previously, Heidi Campbell published an overview of the topic (Campbell 2013), developed in further publications (Campbell-Althenhofen 2015, Campbell-Garner 2016). In a recent overview, Carrie Schroeder develops two central questions on the topic: “what does it mean for Biblical Studies to be marginal to the Digital Humanities when DH is a field positioning itself as transformative for the humanities? How can our expertise in Biblical Studies influence and shape Digital Humanities for the better?” (Schroeder 2016). Using her field, Coptic studies, as an example she shows that the particular skills and needs of a marginal field within a marginal field can be a strong driver in DH.

Consequently, and for the first time at a DH meeting, this ninety-minute panel session asks what is the impact of the digital turn on religious studies and theology, and to what extent these somewhat marginal fields can bring something specific to the big DH tent. They particularly focus on textuality and on the symbolic impact of the “book” as attested to in the expression, “religions of the book,” coined in a programmatic lecture given in 1870 by F. Max Müller (2010). The symbolic, Western impact of books and writing was amplified by this notion, born at the time when the legal status of printed texts and authorship was completely secured in Western culture (Clivaz 2012).

For centuries, “books were perceived as a ‘wide angle’ from which it was possible for everything to be observed, related to, and perhaps even decided” (Carrière-Eco 2009). The panel will consequently consider the hypothesis that the DH have been deeply influenced by this fascination with textuality and books during the first decades of their development; while keeping “the discourse of written texts” as a central pillar to the discussion according to the words of Roberto Busa, a foundational DH figure (Busa 2004). Busa’s relationship to Biblical and religious materials has played a role in his approach to the computing field, as Jones point out (Jones 2016). The double impact of the book and the notion of “religions of the book”, successful in Western culture since the 19th century, provides an opening to understanding why DH in religious fields is still so focused on textuality. Indeed, when we collect examples of DH studies in diverse religious fields, we are unsurprisingly faced with very textual DH (Clivaz et al. 2016e). This observation strengthens the necessity for religions in DH to consider the multimodal and multicultural turn provoked by digital culture.

With these different questions in mind, five panelists will participate in the presentations (sixty minutes in total) and a thirty-minute panel discussion that will be moderated by Claire Clivaz representing the Swiss Institute of Bioinformatics, Vital-IT (Lausanne, CH). The following five speakers have agreed to participate and to discuss the general topic from the perspectives of their own research projects. In alphabetical order:

A Neophyte Proselytizes for Digital Humanities Pedagogy

Emily S. Clark

This presentation explores the ways in which Digital Humanities can enhance a Religious Studies classroom by focusing on two assignments that ask new questions of traditional course materials. The first is a project that was the culmination of a month's work collaboratively amongst a class of 25 students with a database platform (Omeka). This project entailed the digitization of archival photographs of a Native American community from 1916, along with the reading of Jesuit mission material (Clark et al. 2016). The second is an assignment that took two class periods and introduced students to data visualization (Voyant). This assignment introduced students to the differences between close reading and distant reading, along with practicing both on excerpts from Jesuit mission documents (Mentrak – Bucko, 2016).

Topic Modeling the Bible

Paul Dilley

The talk will present the first full-scale topic model of the Bible and related literature in four different languages: Greek, Latin, Syriac and English. It will discuss both technical aspects of the process (e.g., the use or not of lemmatization; retention or removal of function words; optimal number of topics), as well as what we gain from comparing topic models of the same corpus translated into different languages. The presentation will focus on the interpretive gains and losses involved in topic modeling, one of the richest strategies of distant reading to the Bible which has been the subject of centuries of minute examination of the close reading tradition which Moretti has pointedly labeled a “theological exercise” (Moretti 2013).

Digital Lives: Reading Moravian Memoirs in the Age of the Internet

Katherine M. Faull

An international collaborative research project (USA, Sweden, Germany) is developing a digital platform for the investigation of the metadata and text of Moravian memoirs, composed since the mid-18th century by members of the Moravian Church to be read at their funeral (over 65,000 memoirs, housed in Germany and the US, Faull 1997). Less than 10% of the earliest manuscripts have been published. The developing digital interface allows for geospatial and chronological visualization of author’s birth and death place (Haskins 2007). This paper will investigate the intersection of the digital, the autobiographical, and the sacred in the age of the internet. How can the act of reading the lives of thousands of Moravians also be understood as an act of reconstituting the “invisible church” ? (van Dijk, 2007; Eakin 2014).

Material Religions in a Digital World

Rachel McBride-Lindsey

For much of the modern era, religion and theology have been intertwined in a decidedly material world. Over the last several decades, students of religion have begun to carve out intellectual headroom for an approach to material culture that recognizes objects and images as generative sources of theological inquiry and religious practice. Cultural institutions can be an effective tool for inviting researchers and the public into physical spaces and into contact with deeper dimensions of the material world. At the same time, these very contributions work against methodological gains in the study of material culture. Rachel McBride-Lindsay's presentation starts with this tension and draws from pedagogical attempts to incorporate digital platforms into projects anchored in the study of objects.

Exploring developmental patterns within Digital Theology Research within the Digital Humanities

Peter Phillips

Campbell and Altenhofen (2015) explore four waves in digital research development in theology and religion back into the late twentieth century. Their wave pattern picks up both historical and technological trends and patterns in research. However, a three wave theory dominates discussion within introductions to the Digital Humanities, discussed by David Berry (2011) and in the *Digital Humanities Manifesto 2.0*. It tends to reflect modes of research, or groups of methodologies used in research rather than time periods. Reflecting on CODEC's own experience of Digital Theology in association with a range of other scholars, this paper will assess whether too many waves are a problem in our methodological theorizing.

This panel centers queer epistemological formations as they structure the study of digital phenomena. Each of the papers mobilizes the methodological foundations of what Kara Keeling has called a “Queer OS” (2014) -- or an operating system in which “the historical, sociocultural, conceptual phenomena that currently shape our realities in deep and profound ways, such as race, gender, class, citizenship, and ability (to name those among the most active in the United States today), [are understood as] mutually constitutive with sexuality and with media and information technologies, thereby making it impossible to think any of them in isolation” (152). The panelists address core questions including how digital infrastructures mirror and/or model queer and feminist approaches to scholarship, social and artistic practice; what are some possible aesthetic/political retoolings for digital technologies originally designed to surveille and/or maximize female bodies as reproductive vessels; how do social media platforms shift the organizing of live performance cultures?; what are some of the genealogies for contemporary queer digital culture and design?; how can we mobilize theories of interiors and architecture to help us think about the design of online spaces?; what can we learn from long histories of queer social, erotic, political and artistic life that can help us to build online platforms that resist calls to full public access?

These four papers contribute to the larger conversation at the nexus of Digital Humanities, Digital Media Studies, and Theories and Practices of Transgender, Feminist and Queer Cultural Production. Here we bring together the practice of performance art that merges digital technological invention to the long history of feminist body art, and the often invasive politics of digital surveillance and control of women’s bodies, along with the introduction of “Transmedial Drag” as a set of methods for analyzing the digital transfer and potentiality of live performance art, analog queer networks and spaces. We bring this together with a discussion of the development of digital and analog infrastructures for minoritarian spaces and scenes in Mexico City and a material analysis of many of the tropological framings of digital culture--screens, codes and filters--which have been centrally important to the field of feminist design and architectural studies.

Transmedial Drag: Transgender, Feminist and Queer Performance Art in the Age of Digital Reproduction

T.L. Cowan

One of the central foci of Digital Humanities scholarship has been the production of online repositories of previously inaccessible archival materials. Often the project of producing an online repository is generated by the assumption that open access to materials that were once held behind the walls of institutional protocols or hidden in personal collections, is a good thing both for the research community that may want access and for the materials themselves and the lives and events that they assemble. However, as scholars invested in the project of decolonization--including Mukurtu and Local Context co-founders Jane Anderson and Kim Christen--have show us, making openly accessible all of the archival materials collected about a particular community, will very likely violate the cultural protocols of that community. Indeed, the entitlement required to imagine that all materials about a particular community should be made accessible to people who are not part of that community is a perspective with long colonial and imperialist genealogies.

In this paper, I present a range of speculative-pragmatic methods that my collaborators and I have used towards the development of The Cabaret Commons: An Online Archive and Anecdotal Encyclopedia for Trans- Feminist and Queer Artists, Activists and Audiences. Over the course of the past 5 years of community-engaged research, we have worked both to assemble materials from live performance scenes in Mexico City, New York City, Montreal and Toronto to make publicly accessible for researchers and artists alike, and to design the Cabaret Commons as an online platform structured by community protocols, filters, ethics, and aesthetics of the stages and performance spaces that structure the social-cultural scenes that produce these materials.

After years of working with the idea of the Cabaret Commons, I named our method “Transmedial Drag,” and have elaborated how we work in the mode of transmedial drag along with co-investigator Jasmine Rault, and collaborators Dayna McLeod, Carina Guzmán and Robyn Overstreet as well as many performance artists with whose work we are in conversation.

“Transmedial drag” is the method of study, knowledge production and citational practice involved in moving across media/mediums (for example, from live performance, to video documentation, to digital archive to online platform), which creates a sort of pastiche of the ‘original,’ denaturalizing its status as ‘originary’ and teaching us something new about the excesses and limitations of each media form. Riffing on Judith Butler’s game-changing theorization of drag as a performance that, “[i]n imitating gender ...reveals the imitative structure of gender itself--as well as its contingency” (Gender Trouble 138). Or, thinking through Benjamin’s anxieties about transmedial transfer in the early 20th Century, it’s what we might call *the work of queer performance art in the age of digital reproduction…!* Thus we practice a process-heavy collaborative protocol that seeks to “simulate,” not just the “aura” of live performance, but is also structured by locally-specific, community-based social and political ethics as manifested in minoritized cabaret scenes. Transmedial drag compels us to reckon with the cultural and ethical limitations of digital accessibility in the face of technical possibility (cf. Robertson 2016).

The decolonizing, community-collaboration and accountability methods for the digital transmission of traditional Indigenous knowledges, practiced for example by the projects Mukurtu and Local Contexts, provide a generative model for negotiating this paradox of intimate privacies and networked cultural histories and memories. Indeed, Indigenous studies has pointed out the colonial and Westernexpansionist logics and impulses underlying the push to open-access and digitization, and have developed networked information management and archiving systems that follow indigenous cultural protocols, prioritizing privacy and multi-tiered user-generated-access levels.

What we're calling transmedial drag refers to the troubling excess that remains in even the most 'successful' transition from one medium or digital form to another – those elements that are incompatible to the form/medium as it currently exists and compel us to ask whether the form/medium exists *because of* these constitutive exclusions, or on the condition that certain elements remain excessive/external. Indeed, what remains excessive, incompatible and bit of a drag on the seductive techno-cultural possibilities of openness, are things like labour, consent, privacy, the agency and will of research-collaborators. For those of us trained in gender, sexuality, critical race, post and decolonial research, it becomes clear that our scholarly fields and practices of digital media and digital humanities can be sustained by reproducing a familiar set of constitutive exclusions -- those skills, values, techniques and priorities cultivated by and for the survivance of women, people of colour, indigenous people, trans people, queers, etc.

Transmedial drag is indebted to Elizabeth Freeman's work on 'temporal drag' and Heather Love's on "feeling backward" -- or the ways that queerness is often experienced, expressed or interpreted as an attachment to the past, as a stall in personal or social development, a drag on cultural-temporal progress narratives. We are also indebted to Kadji Amin's work on transgender temporalities, which allow us to understand the ways that "transgender experiences are constituted by yet exceed normative temporalities" and the necessity of incorporating asynchronic temporalities "in order to do justice to the complex ways in which people inhabit gender variance" (220).

With Love, Freeman and Amin, our digital research-creation project is oriented to those people, scenes, cultures, affects and knowledges cast as a drag on the forward-momentum- digital-entitlement fantasies of unfettered access to everything, everyone, everywhere -- fantasies that resonate so strongly with the gender, sexual and racial histories of colonial-modernity that we know too well. Thus in true queer epistemological form, "transmedial drag" is both a method of study modeled on queer performance and theories of performativity (i.e. Butler) and a conceptual framework through which to make sense of elements of cultural life and work that are generally unintelligible (nonsense).

Like the deep cultural understandings, consultation, collaboration and re-engineering that led to the development of Mukurtu and Local Contexts, we imagine culturally-sensitive and specific software that prioritizes highly nuanced **cultural** logics, protocols and specialized knowledges in the development of **computational** logics, protocols and specialized tools, towards what Kara Keeling calls a "Queer OS/operating system". Keeling's QUEER OS is an operating system in which the "historical, sociocultural, conceptual phenomena that currently shape our realities in deep and profound ways, such as race, gender, class, citizenship, and ability (to name those among the most active in the United States today), [are understood as] mutually constitutive with sexuality and with media and information technologies, thereby making it impossible to think any of them in isolation" (152).

Indeed, transmedial drag denaturalizes the constitutive exclusions of most of our media and information technologies; lets us both recognize their limits and imagine their necessary transformations; **and** puts into relief some of the dynamics of cabaret that continue to sustain trans- feminist and queer scenes and lives **even within** media environments that are designed around their impossibility and imperceptibility.

In this moment when new digital archives of minority and subcultural scenes seem compelled to reproduce perilous Web 2.0 logics of unbridled open-access -- based in modern-colonial entitlement fantasies of absolute accessibility -- the Cabaret Commons is using trans feminist and queer relational epistemologies towards the decolonizing project of ethical collective platform protocols for sensitive cultural memory, heritage projects and accountable digital design. This is part of a larger epistemological-transformational project to decolonize both trans- feminist and queer practices, and the dominant digital cultural practices that assumes that all networks are networked publics leading us to theorize what we're calling networked privates.

The hope that we have for the Cabaret Commons is that it will bring the activated characteristics of cabaret performance, as well as other grassroots and politically-engaged live performance (like street performance, marches and protest arts -- what Mexican artist/activist Jesusa Rodríguez calls "mass cabaret") along with their translocal trans feminist and queer scenes, ethics, politics, social and sexual lives to bear on digital archiving infrastructures.

Screens, Codes, Filters: sapphic modernist design genealogies for queer digital culture

Jasmine Rault

What can early twentieth century modernist architecture and design teach us about contemporary decolonizing, feminist, queer and anti-racist practices and protocols for networked digital architecture? Euro-Atlantic modernist architecture was driven by ideals of internationally standardized open communication – beyond the mass rail, steamboat and automobile distribution of low-cost print media and photographic reproductions towards material changes like the open floor plan, strip windows and glass walls, unimpeded visual access to interior and exterior space, eliminating walls and structural as well as decorative or symbolic obstructions to complete open access. There are some striking ideological continuities between these modernist architectural ideals (and aesthetics) and contemporary Euro-Atlantic values of unbridled digitization, designing global information networks for unobstructed open access – and these continuities need to be understood within a context of modern-colonial regimes of gender, sexuality and race. My presentation focuses on early twentieth century women's queer interventions into modernist architectural and design ideals as a genealogy to contextualize, better understand and support recent innovations in decolonizing, queer, feminist and anti-racist designs for networked digital practices, archives and spaces. I draw from my research on Eileen Gray – which explores some of the intersections between histories of communication, European architectural modernity and sapphic modernity, or the cultural history of female sexual dissidence – and my collaborative research on "the Cabaret Commons," designing a networked digital archive for trans feminist and queer performance artists, activists and audiences.

My research on Gray, and her contemporaries in queer interior designs, shows that modernist architecture was invested in creating not only new buildings and living spaces, but new bodies and subjects. As such, modernist architecture was contributing to the modern production and regulation of sexuality, race and gender. Moreover, from around 1900 to 1935, modernist architecture was increasingly committed to communicative clarity – or immersive living spaces of total communication – and several sexually dissident female artists, writers, interior designers and architects, like Eileen Gray, worked to interrupt this clarity. Indeed, women in the US, Canada, Western Europe and the UK worked on domestic interior design to work out new possibilities for gender and non-heterosexualities.

I focus on the creative extent to which these possibilities depended on codes, screens, filters – as interpretive and communicative strategies, but also as design materials. That is, the aesthetic, social and cultural phenomena of female gender and sexual queerness was enabled at the start of the 20c through complex claims to privacy. My presentation draws connections to my current book project, co-written with T.L. Cowan, provisionally entitled, *Checking In: Feminist Labour in Networked Publics,* which takes up the ways that similar claims to mediated privacy are emerging as central concerns in the design of very different spaces – online digital designs for networked trans-feminist and queer archives and social memory.

We are currently working with the data set of the digital (digitized) archive of the Meow Mix Cabaret, a show and dance party for "bent girls and their buddies" which ran in Montreal from 1997-2012. Technically, we have been granted permission by the copyright holders to make this archive public through an online platform. However, through interviews with individual performers who have appeared on the Meow Mix stage over the years, we've learned that a majority of the artists are not interested in reproducing or getting involved in the distribution of a full-run, open-access digital archive of their materials – for many reasons: including low or degraded quality of the video and images; the unpolished/amateur aesthetic of their work at an earlier stage of their careers; the fact that they did the performance *for their friends* or for a particular event and do not want broad circulation that will leave a digital trace; gender, sex, sexuality, body shape and size transitions; nudity; and the potential hazards of being associated with trans- feminist and queer scenes. However, many artists are interested in *some* of their work being available online for *some* people. And thus by working through what we are calling a speculative/pragmatic method of transmedial drag, we are designing an online space in which this kind of mediation will be possible.

In this presentation, I suggest that understanding the architectural innovations of Gray and her contemporaries, who built on the premise of mediated privacy, on filtered access, offers us a unique genealogy to studying and designing digital architecture that respond to similar needs and desires for online spaces through which minoritized subjects push back against the dominant pressure for full publicity, for the full availability and open access to our online selves, socialities and intimacies. The metaphor of architecture is often used in reference to online built environments but rarely is the metaphor pushed to a point of usefulness. Danah Boyd has argued that "what it means to be public or private is quickly changing before our eyes and we lack the language, social norms, and structures to handle it" (2007). Indeed, queers, people of color, indigenous people, trans folks, and disabled people are hacking popular social media corporate sites like Facebook, Twitter, Instagram, Snapchat, etc. to build differentiating filters in order to choose which *selves* to "out" in which contexts, and organizations like the Feminist Technology Network (FemTechNet), the Center for Solutions to Online Violence (CSOV), FemBot, Crash Override (Zoe Quinn & Anita Sarkesian) are working not only to build these infrastructures but also to communicate the differential consequences of total publicity, open access, or the digital 'open plan.' That is, we can see the development of networked 'privates' rather than the fetishization of 'networked publics' and we are working on collective action towards, what we might have learned from Gray and her contemporaries: techniques of mediated privacy.

Queering the Vaginal Canal: Make Art Here

Dayna McLeod

My presentation will examine how feminist performance artists have employed explicit performance-based practices in their work, specifically by using their vaginal cavity as a site of art production. I will compare these works, practices, and methodologies with my own, specifically citing **Uterine Concert Hall**, a vaginal media work that features my body as a concert venue. Equipped with a 54 kHz internal speaker (Babypod), my vaginal canal acts as the stage with my cervix as the proscenium, for the audience of my uterus. A live DJ pumps sound directly into me via 6-foot cable that reaches from their booth. My vaginal canal is the scene of the performance and the instrument of its production. I can feel the DJ's varying frequencies, pitch shifts, and throbbing tones while external concertgoers are invited to eavesdrop via stethoscope, on the faint echoes of the recital through the very flesh of my body. Like showing up to a concert and listening from outside, this piece purposefully excludes external listeners while engaging with explicit performance-based production practices, and feminist art practices of intimacy.

In *The Explicit Body in Performance*, Rebecca Schneider identifies Annie Sprinkle's cervix, viewed similarly through a medical device (a speculum) in *Public Cervix Announcement* (1990-1992), as a "theoretical third eye," a countergaze that looks back at the viewer who is gazing at Sprinkle's cervix (55). In **Uterine Concert Hall**, the viewer's gaze and concentrated attention is focused on me and on the message my body embodies for their speculation: the spectator sees, hears, and touches my body while I absorb both the concert through my vagina and their expectations. My "theoretical third eye" listens. Schneider also notes that "any body bearing female markings is automatically shadowed by the history of that body's signification" (20), and the invasive imagined construction of that body. For an external audience to **Uterine Concert Hall**, my uterus-as-intended-audience - cervix-as-proscenium - vagina-as-stage, all become a singular blank screen of possibilities for viewers to project their fantasies onto: to imagine its appearance and construction, and imagine what sounds might emit from my flesh. How might my body distort or otherwise enhance the anticipated DJ set? (How) does sound transform the body (my body)? By the time the viewer arrives at my side where they are handed a stethoscope to eavesdrop into/onto/through my flesh, their anticipation and fantasy is confronted by the very real presence of the mise en scene. Here they are featured in the role of pseudo-physician, which is complicated by issues of consent, interior/exterior bodily access, and their demands of the body (my body) as sound medium.

This outsider, exclusionary status that the viewer is assigned also comes with a controlling, medicalized, obstetrical gaze. In Canada and the United States, we employ much monitoring of women's bodies through our expectations of how women look, behave, act, and feel. These expectations are pathologized, reinforced, and legitimized through medicalized surveillance and control. Invasive and non-invasive examinations and procedures like ultrasounds, transvaginal probes, and visualizing and monitoring technologies are normalized for bodies marked female who are evaluated by a normalized and medicalized gaze in relationship to potentially housing or not housing a fetus (Balsamo). "Protection of the fetus is often offered as a commonsensical, and, hence, ideological rationale for intervention into a woman's pregnancy, either through the actual application of invasive technologies or through the exercise of technologies of social monitoring and surveillance" (Clarke and Olesen). **Uterine Concert Hall** is not a place for babies, fetuses, or heteronormative determinism. However, it is a site that questions these cultural assumptions of women's bodies, of what we expect from bodies marked female, and why we think we have the right to make any kinds of demands on these bodies in the first place. This project does this by using digital technologies and affordances to interrupt their intended functions (i.e. playing music for a uterus-bond fetus from an adjacent vaginal canal) that contribute to the medicalized surveillance and control culture of women's bodies.

In this panel presentation, I am also interested in discussing **Uterine Concert Hall** in its queering of the uterus as a viable physical space, the performing body, and the artist-audience exchange. Further, I am interested in putting **Uterine Concert Hall** in conversation with the works and practices of artists who have similarly used vaginal and uterine space *as* physical space as the site of their works' production, like Annie Sprinkle's *Public Cervix Announcement* (1990-1992), Carolee Schneemann's *Interior Scroll* (1975), and Casey Jenkins' *Vaginal Knitting* (2013).

"How many lesbians does it take to flyer for a party?". The impact of shifting digital landscapes on queer women's nightlife organizing in Mexico City since 2005.

Carina Guzmán

In this paper, I open an inquiry on how the evolution of the digital landscape has brought shifts in the strategies of queer women's nightlife organizing in Mexico City since 2005, and what the possible implications of these shifts are.

Following Cowan and Rault's concept of transmedial drag, I ask if and how social media platforms and media such as memes, used as organizing/political tools, can possibly take the shape of/mimic/reflect the queer world-making of the social scenes they are being used to create, especially when contrasted with the resources they have replaced such as e-mails or flyers, which necessarily imply physical contact between organizers and the queer crowd. I pay special attention to independently organized events held outside the circuit of commercial gay nightlife venues; dance parties and cabaret revues in adapted spaces such as *azoteas* and *casas de cultura*. This leads me to consider the intersection of labour, material culture, digital culture, and the sexual politics of place-making. At the same time, I consider the shift within digital culture that has happened with the emergence of social media as an organizing tool, and memes as political statements.

In my doctoral research in the Communication Studies program at Concordia University I have established, partially through an autoethnographic narrative, that independent and capitalist-alternative lesbian and queer women's nightlife organizing in Mexico City is a political project that responds to issues of economic gender disparity and spatial justice.

The small lesbian collective *Meras efímeras* was formed in 2005 by a group of friends I was a part of to organize nightlife alternatives for queer women in Mexico City. At the time, the main nighttime recreational events for queer women were "ladies' nights" at gay men's bars and clubs. Though inexpensive and conveniently located in the city's gay ghetto, these were not especially well organized; patrons could often find poor service, strip shows that made some feel uncomfortable and unclean facilities. It was evident that they were held to create a niche clientele on slow weeknights.

Meras efímeras contended that within the capitalist logic of commercial nightlife, a queer women's crowd could not "compete" with an audience of gay men, making it virtually impossible to find women-oriented or women-welcoming queer events on the weekend. We, thus, understood that independently organizing nightlife implied taking a political stand on the economic disparity between men and women, and the issue of spatial justice for queer women in the urban nightscape. This also implied we could not expect to be paid for our work. And, as we were also unable to pay rent at a club, we had to physically adapt spaces or negotiate agreements at other types of venues outside of the gay ghetto.

Today's use of memes to make political statements, as well as the use of platforms such as Facebook event pages, Twitter and Instagram as an event organizing tools contrasts sharply with what it was like to call on a queer crowd for a political/social event around 2005. Our main digital resource was a Yahoo! Groups mailing list to which we would manually add e-mails requested at the door of our events. We also advertised in the local LGBT free weeklies. But, the first point of contact were flyers we'd drop off at businesses or hand-out outside "ladies' nights" events.

In this paper I establish that the simultaneous use of paper-based and e-mail group based strategies *Meras efímeras* employed around 2005 constitute a pre-social media-as-we-know-and-use-it-today organizing landscape that straddled material and digital culture. While this strategy was partially material and partially digital, it necessarily implied exchanges made physically; handing out of the flyer on the street, requesting and giving an e-mail at the door of an event. So, this paper also asks what are the stakes in queer women's nightlife organizing, as a political project, in the transfer from organizing strategies that implied a physical presence to current social media resources. Moreover, I ask if resources such as memes, Facebook event pages, Tweets or Instagram are capable of an effective transmedial drag; can they properly represent queer women's nightlife political world-views?

Anna Kijas
kijas@bc.edu
Boston College, United States of America

We use the phrase "high-resolution musicology" to We use the phrase "high-resolution musicology" to refer to the increasing level of detail being captured, processed, and displayed in digital tools for cataloguing and searching early music sources. These tools are made possible by the widespread availability of several technologies. High-quality digital imaging provides extremely detailed views of source materials. Co-operative cataloguing efforts have captured page-level information, allowing work-level data to be linked from one source to another in relational databases. The Music Encoding Initiative is driving renewed efforts to encode the underlying semantics and process of the music notation rather than treating notation simply as a visual medium. The papers presented in this session will demonstrate the convergence of digital imaging, data modelling, detailed cataloguing, and semantic notation encoding in medieval musicology, and will relate experiences and lessons learned in building these tools.

In *The Burns Antiphoner – From manuscriptto interactive resource,* Ben Florin and Anna Kijas report on a new project based around a 14th-century source, the Burns Antiphoner. In this project they focus on integrating and delivering images, metadata, and recorded audio and video to provide an in-depth look at the contents and experience of this particular source. Using high-resolution web-based image display technologies, they provide users with the ability to view small details on the page images, while integration with data collected in the CANTUS database provides a detailed view of the musical contents of each image, including liturgical function. A novel in-browser search system based on Lunr.js provides users with full-text and field-based search capabilities. Finally, Florin and Kijas explore the possibility of using Music Encoding Initiative (MEI) standards to encode and render the musical incipits, providing a valuable and open data source for publication and re-use. Karen Desmond further explores the use of MEI for medieval musicology in *Measuring Polyphony: A project to encode the semantics of the context-based (and under-prescriptive) notation of late medieval music.*

Previous projects have involved an implicit or explicit translation to either a purely visual medium (for the purposes of print or display), or to a system of notation encoding that treats medieval music as though it were written using modern notation. This paper explores how medieval music might be semantically structured using the Music Encoding Initiative, such that figures representing time and proportion in the music remain contextually related. This work represents a new direction in historical music notation encoding, and will provide an account of the technical and representational challenges encountered in the process.

The Digital Image Archive of Medieval Music (DIAMM) is one of the longest continually-operating digital musicology resources. Recent changes to the ways in which cataloguing data is captured, presented, and made available to others, however, present new opportunities for researchers to interact with this digital collection. Andrew Hankinson and Julia Craig-McFeely describe their efforts at promoting granular data accessibility in both human and machine-readable representations, following established and emerging standards to promote data integration and re-use within other projects.

The Burns Antiphoner – From Manuscript to Interactive Resource

Ben Florin, Anna Kijas

The Burns Antiphoner (is a collaborative project between the Digital Scholarship Group and library staff at the Boston College University Libraries, musicologist Dr. Michael Noone, and several external partners, including CANTUS database staff. In the summer of 2015 we began encoding afourteenth-century Franciscan Antiphoner using the Music Encoding Initiative (MEI) standards, as well as developing an open-access site to present the manuscript as an interactive object for research and scholarly use.[1] The original Antiphoner is in manuscript form bound between leather-covered boards containing 119 parchment folios with text and notation for antiphons and responsories for the entire annual calendar of saints' days (sanctorale).

This paper will examine the workflow and development of this project and the main goals, which included:

1. Making the Antiphoner interactive by building an open access and responsive website with Diva.js, a dynamic presentation layer that can search and display content (data, notation, XML/MEI) and multimedia;
2. Using and developing open source technology to encourage and support further development in the open source community, as well as, sharing of documentation and data;
3. Contributing our data to the scholarly community through a collaboration with CANTUS, a database for Latin Ecclesiastical Chant; and
4. Developing software, workflows, and documentation that can inform future projects using similar technology.

Key infrastructure and application choices used in this project will be discussed, including the implementation of Diva.js as the presentation layer to pull in our data via a JSON file, Lunr.js to index our data directly in the browser, and the use of IIIF, which will enable interoperability of our images across different platforms and potentially allow us to test our data with optical music recognition (OMR).

The workflows for transcribing and encoding approximately 1500 incipits for our project and the CANTUS database will be explored, including some challenges that came along with this project, which was our first endeavor in using MEI. The neume notation is currently rendered as Volpiano font, but Verovio would be preferable so that the encoded incipits in MEI XML could be rendered directly. Verovio is a software that renders MEI directly in a modern browser as SVG (scalable vector graphics: XML-based vector image format). At this time, however, while Verovio can render MEI files that use mensural elements, it cannot yet render those associated with the MEI neume module. In addition, we will discuss our ongoing explorations, which include presenting the antiphoner in a multitouch environment and investigating the application of OMR on our IIIF image manifests, containing encoded text and musical incipits from the manuscript.

Measuring Polyphony: a project to encode the semantics of the context-based (and under-prescriptive) notation of late medieval music

Karen Desmond

'Measuring Polyphony' is a project that digitizes polyphonic music of the late medieval period. The goals of the project are threefold: 1) to make transcriptions and sound files of this repertory freely available online to performers, scholars, and the general public, alongside images of the original music manuscripts; 2) to encode the medieval notation in a standardised machine-readable format so that the music can be searched or analysed using current tools, and through this interoperability the data made available to other websites and applications; and 3) to streamline the processes and tools for encoding this repertory so that other stakeholders can easily and rapidly enlarge the dataset.

The availability of high-resolution images of most manuscript sources of medieval polyphony since the late 1990s, in particular through the groundbreaking open-access DIAMM initiative, and also library-based repositories such as Gallica, has heightened scholarly awareness of the importance of considering medieval music within its original material context. The major print editing projects of the mid-twentieth century divorced the musical texts from their parchment and ink origins, segregating them into composer- and genre-ordered collections, converting their notation to modern equivalents, and secreting away detailed philological considerations and any commentary pertinent to a specific manuscript or scribal practice into cryptic appendices. Now, however, the easy access to so many different music manuscripts in the (virtual) flesh has encouraged scholars to think again about the meaning of music compositions as it relates to the manuscripts in which they are found.

This project, started at McGill University, with the support of SIMSSA project and the Schulich School of Music, and now continuing at Brandeis University, leverages the potential of these rich image repositories and the availability of community-based standards for encoding music notation. While encoding music notation is considerably more complex than encoding text alone, fortunately the standards developed by the Music Encoding Initiative (MEI) community have emerged in recent years as the standard way to encode music notation documents as XML. Most of the current projects that encode music notation, however, are focused on repertories written in the neumatic notations of western plainchant, or from the common practice period of c. 1600 and later. ‘Measuring Polyphony’ is the first project that encodes medieval music as it was originally notated in mensural notation--a notation system developed in the late thirteenth century in order to more precisely denote rhythm in polyphonic music, and which continued to be used until the sixteenth century. Mensural notation presents additional difficulties for encoding since it is a context-based notation. In other words, whereas the shape of a note and its duration are in a one-to-one relation in notation from the common practice period, this is not the case with mensural notation, where the same note shape can be used in different contexts to denote different durations.

The repertory chosen for the first phase of this project is a representative sample of sixty-four motets transmitted in the major sources of French polyphony that were copied c.1300-1375. This paper will describe the process by which the mensural notation was encoded, and the encoded transcriptions (and audio realisations) displayed on the fly using Verovio, an open-source library for engraving MEI music scores into SVG.

The encodings, at present, capture the diplomatic transcription of each composition from one manuscript source: the transcriptions, however, allow for the possibility of later adding alternative readings from concordant sources (through the Critical Apparatus module of the MEI schema), and thus for the possibility of extending these encodings to produce online critical editions of these compositions. Medieval notations are often under-prescriptive, and these encodings also allow for flexibility in imposing particular pitch or rhythmic interpretations, so that future interfaces could allow users to easily switch back and forth between differing editorial interpretations. In addition, the availability of this first dataset of a medieval repertory encoded in mensural notation, along with the tools and documentation enabling others to rapidly add to this dataset, opens up new possibilities for the analysis and interpretation of fourteenth-century music, and enriching our understandings of the the visual notation systems developed to represent and record it.

Building the new DIAMM: Linking and sharing data for medieval musicology

Andrew Hankinson and Julia Craig-McFeely

The Digital Image Archive for Medieval Music (DIAMM) is perhaps the longest-running digital resource for medieval musicologists. First launched on the World Wide Web in 1998, it has provided countless researchers, performers, and enthusiasts with a glimpse into libraries’ and archives’ collections through the use of high-resolution digital imaging and authoritative cataloguing and description efforts. In November 2015, work started on the third iteration of the DIAMM web resource, with renewed efforts on providing enhanced search and discovery interfaces, data sharing, and image resource sharing, in an effort to provide a platform for new applications in digital musicology. This presentation will provide a progress report on this work, as well as introduce users to some of the new features and capabilities afforded by these developments.

Background

The DIAMM database currently catalogues 3,375 medieval and early modern manuscripts of monophonic and polyphonic music (excluding chant). The project has high-resolution digital images of 710 sources, from which we have permission to publish 45,626 images online. Most of these images are natural-light photographs, but for a few sources we also make available 1,733 alternate images, including those shot in alternate light sources (Ultraviolet, Infrared), with transmissive light, digitally enhanced, or digitally restored images.

In addition to descriptions and images of manuscript sources, we capture extensive data about the contents of these sources. Musical compositions and textual sources are related to the individual pages in the sources, giving us the ability to identify the presence of a particular musical work across several different sources and navigate directly to the page image where it can be seen. The roles of people and organizations may also be traced across sources. For example, a record for a given individual may link to the sources and works where he acted as copyist, owner, or composer.

With previous versions of the DIAMM website, corrections and additions to the contents were extremely slow. This was due to a number of technical challenges in the publication workflow, translating the local FileMaker database to a MySQL database for publication. In the new version, we have moved to an online updating model, where content updates may be proposed by our community of users, after which they are reviewed for inclusion and made available immediately, with appropriate credit for the change acknowledged on the object record.

Addressability and Linked Data

The central organizing principle behind the new DIAMM website is the creation of unique, understandable, and resolvable resource URLs following the principles of Representational State Transfer (REST, see Fielding, 2001). A resource is defined as the objects, or "things" in the database: A manuscript source, a person, a geographic area, and so on. The URLs are designed to function as permanent and globally unique identifiers for both human- and machine-readable representations of these resources. To give an example, the URL https://www.diamm.ac.uk/sources/202/ refers to the record for the Eton Choirbook (GB-WRec MS 178). By default, loading this URL in a web browser will return the HTML version of the record for human readability. However, a machine-readable representation of this data is also available at the same URL using "content negotiation," a process through which different representations of the same record may be requested when the URL is retrieved. Asking for the content type of "application/json" will return the machine-readable JavaScript Object Notation (JSON) representation of the same data.

We designed this URL scheme to promote integration of DIAMM data within third-party applications. In many cases, DIAMM records are the only digital representations of a manuscript, person, or organization. A canonical and globally-unique URL record allows these entities to be represented in other applications, and the data we have captured about these objects can be integrated within other applications, enhancing and extending the qualities and relationships of these objects.

The International Image Interoperability Framework

The International Image Interoperability Framework (IIIF, Snydman et al, 2015) is an emerging standard, promoting a common format for delivering and structuring digital image collections. The IIIF specification is composed of two primary recommendations: The Image API, and the Presentation API. The Image API defines a common URL structure for addressing images, or regions of images, and delivering these images to a user's browser. The Presentation API defines a data structure for combining sequences of images into a coherent collection. For example, the images representing the pages of a book would be contained in a Presentation API document. The Presentation API also contains further functionality for delivering document metadata, such as bibliographic information or document structure (e.g., the pages representing the start of chapters in a book or sections in a newspaper).

For the DIAMM website we provide IIIF Presentation API documents for all sources for which we have images, and deliver our images through a IIIF Image API-compatible image server, the IIP Image Server (Pillay, 2016). Due to licensing restrictions with our partner libraries, however, the availability of images and IIIF manifests are restricted to our users who have signed in. In the next phase of our project, we hope to review these agreements to facilitate open delivery of source images to the wider public.

In addition, we have integrated IIIF manifest viewing into the source records we publish. With this change, we are able to incorporate images from other libraries' collections into our own without needing to host and re-deliver these images from our own website. If, for example, a library publishes a IIIF manifest for a particular source, we can display these images immediately on our website, with the image content delivered from the library directly. We hope this will greatly reduce the latency with which we can make images available to our community of users, and we encourage all libraries and archives to ensure their image collections are made available as IIIF-compatible sources.

A new platform for medieval musicology

The new version of the DIAMM website will continue to serve as an important destination site, available for consultation and discovery for our community of users. With the enhancements described in this presentation, however, it will also begin to serve a new and more active role within the field of digital musicology. Using DIAMM data, and providing machine-readable and addressable resources, the data from the DIAMM site can have a life outside of our own website. We anticipate that new capabilities in data availability, and a standards-based approach to content addressability and machine readability will promote re-use and integration ("mash-ups") within other tools.

Over the last five years, research computing has undergone a shift from focusing on running infrastructure for highly technical researchers, primarily in the sciences, to supporting medium- to large-scale computational needs across a wide range of disciplines, where practitioners fall across the spectrum of technical proficiency.

This shift in approach has opened up new opportunities, both for scholars whose research questions are facilitated by computationally intensive algorithms (e.g. photogrammetry, natural language processing, OCR at scale), and for humanists in support positions that require translation between technical and non-technical audiences. This panel will discuss opportunities for research and career development through the perspectives of research IT staff whose backgrounds in both humanistic inquiry and computational and digital methodologies enable them to engage in outreach to, training of, and support for humanities researchers. It will also provide practical suggestions for humanists who could benefit from research computing resources but find it difficult to navigate the expectations of research IT organizations.

The communication, writing, and teaching skills cultivated through an advanced degree in the humanities align with employment trends in research IT groups. While some familiarity and comfort with computation is generally a requirement for working in research IT, advanced programming or system administration skills are crucial for a minority of positions in these groups. As the mandate of research computing groups has expanded, it has become increasingly clear that successful research computing programs require documentation that is comprehensible to a non-technical audience, hands-on workshops for non-specialists, and staff capable of understanding the fundamentals of researchers' work and identifying effective approaches to meeting their computation needs. To that end, in 2014 the US National Science Foundation funded the Advanced CyberInfrastructure - Research and Education Facilitators (ACI-REF) program, which developed a cohort of computation "facilitators" across a number of universities who could "maximize the impact of investment in research computing" by "assist[ing] researchers in leveraging ACI resources for themselves" and sharing solutions among participating institutions (NSF 2014). This approach to providing support has been highly influential among campus research IT organizations, and related workshops such as the ACI-REF virtual residency (featuring plenaries such as "Effective Communication: How to talk to researchers about their research" and "Writing Grant Proposals") have drawn large crowds (Neeman et al. 2016).

Similarly, the Extreme Science and Engineering Discovery Environment (XSEDE), funded by the National Science Foundation, has begun specifically reaching out to disciplines that have been typically under-represented in the high performance computing arena, including those in the humanities. XSEDE has a program called Extended Collaborative Support Services (ECSS) that partners humanities scholars and others from under-represented areas with computing professionals who can help them achieve their desired research objectives (Wilkins-Diehr et al. 2016). This has been both necessary and fruitful particularly in areas that are focused on data analytics (such as video analysis, image analysis, network analysis, etc.), as opposed to the more traditional simulation and modeling done by scientists and engineers. XSEDE's Novel and Innovative Projects group includes a specialist in digital humanities, as well as specialists in pertinent related areas such as big data analytics.

Along the same lines, in January 2014, Compute Canada hired a full-time Digital Humanities coordinator to lead a national team supporting researchers wanting to engage with national advanced research computing (ARC) resources. Compute Canada, a national non-profit organization incorporated in 2012, plans and oversees pan-Canadian ARC resources used for big data analysis, visualization, data storage, software, portals and platforms for research computing serving Canadian academic and research institutes. The national support team for Compute Canada now consists of the full-time DH coordinator, and a large geographically dispersed team that meets bi-weekly to coordinate national initiatives like training at the Digital Humanities Summer Institute and national competitions such as the recent partnership between Compute Canada and the Canadian Social Sciences and Humanities Research Council. The DH team also meets locally with humanities researchers at their own institutions to help them leverage national infrastructure, and shares experiences and advice back to the national team to help in developing tools, services, and training opportunities that will benefit the national DH community (Simpson 2015).

One of the interesting ramifications of these changes in IT staffing trends is the addition of humanists to IT-based groups in high performance computing, cyberinfrastructure, visualization, and data architectures--humanists who are called upon to maintain both a deep understanding of computational systems, as well as track the needs of scholars in the humanities, which tend to be quite different from researchers in the “hard” or social sciences. Often, they are the lone humanist in a group dominated by engineers and computer scientists. There is a clear need and desire to expand the use of computational resources into "non-traditional" (i.e., non-hard-sciences) disciplines, both to justify an institution-wide investment in research computing, and as a way of building institutional capacity for supporting digital humanities scholarship (as described in the forthcoming 2017 ECAR/CNI white paper on institutional digital humanities support). Nonetheless, institutions are struggling with translating their services into comprehensible and relevant offerings for humanities researchers. Finding effective means of supporting these researchers within the traditional model of the research IT group has also been a challenge, given the ways that it differs from library-based support models with which scholars are more familiar. Panelists will reflect on projects they have worked on that successfully bridged the humanities-research computing divide, to the benefit of both groups.

As one example, at Indiana University, a workflow for teaching text analysis with R has been developed that uses web-based Shiny scripts to introduce an algorithm, highly annotated RNotebooks explaining each line of code, lightly annotated RScripts allowing for remixing and adaptation, and, finally, RScripts to leverage multicore environments. The scripts use data both from literature and Twitter, and these tutorials consistently draw the highest attendance in the series DH for Humanists, held throughout the semester. Individual research projects using more sophisticated algorithms such as NER and LDA have also grown out of this project.

As another example, at the University of Chicago, the recently-developed Visual Text Explorer provides a new type of framework for reading texts along with a range of user-customizable analytics, allowing for simultaneous close and distant reading. Other humanities research computing projects include web-based data-driven animated interactive mapping systems, tools for comparative sequence analysis across literary corpora, and automated aggregators of ranges of specific secondary data sources to inform the reading of specific texts/types of texts, all of which require no knowledge of computer programming by the user but nonetheless leverage research computing resources.

At UC Berkeley, 3D modeling work by Near Eastern Studies scholars that uses photogrammetry software running on the high-performance compute cluster has been helpful for testing new Graphics Processing Unit (GPU) nodes in the cluster.

Finally, panelists will provide recommendations for how humanities scholars can translate their research projects in ways that will make them more comprehensible and compelling for institutional research IT groups that may not have a humanist on their support staff.

Panel participants

Quinn Dombrowski is the Digital Humanities Coordinator in Research IT at UC Berkeley. Research IT supports research data management, museum informatics, and computationally intensive research across all domains. She is the author of *Drupal for Humanists* and has an MA in Slavic linguistics and an MLIS from the University of Illinois.

Tassie Gniady is the manager of the Cyberinfrastructure for Digital Humanities Group at Indiana University. The CyberDH group focuses on workflows for text analysis and photogrammetry. She also teaches an Introduction to Digital Humanities course in the Information and Library Science School. Tassie has a Ph.D in early modern literature from UC-Santa Barbara and an MIS from Indiana University.

Megan Meredith–Lobay is the Digital Humanities and Social Sciences Scientific Analyst for the University of British Columbia’s Advanced Research Computing Department. She is also part of WestGrid and Compute Canada, the Canadian HPC national infrastructure platform. Megan has a PhD from the University of Cambridge Department of Archaeology in which she explored the early Christian archaeology of Argyll, Scotland using GIS and early online archaeological databases.

Lisa M. Snyder is the director of Campus Research Initiatives for UCLA’s Office of Information Technology, and manager of the GIS, Visualization, and 3D Modeling group for the Institute for Digital Research and Education. She has a Ph.D. in Architecture and teaches Virtual Reality and 3D Modeling in UCLA’s digital humanities program.

Jeffrey Tharsen is Computational Scientist for the Digital Humanities at the University of Chicago where he is the lead technical domain expert for digital and computational approaches to humanistic inquiry. Jeffrey has a Ph.D. from the University of Chicago's East Asian Languages & Civilizations department, specializing in the fields of premodern Chinese philology, phonology, poetics and paleography.

Recent work in the digital humanities has moved away describing the digital humanities as a “big tent,” to quote William Pannapacker’s famous 2011 post. Taking inspiration instead from the multiple histories and temporalities of media archaeology, such research emphasizes the local contexts where technological and institutional history take place. Matthew Kirschenbaum’s identification of the digital humanities in 2014 as a “discursive construction” that ignores the “actually existing projects” of the field set the stage for scholars to rethink how the digital humanities conceptualizes its work and its history (“What Is” 48). More recently, in the introduction to *Debates in the Digital Humanities 2016*, Matthew Gold and Lauren Klein use the scholarship of Rosalind Krauss who, in 1979, described art history as emerging as “only one term on the periphery of a field in which there are other, differently structured possibilities.” Whereas Krauss saw this as a failure of art history, Gold and Klein celebrate the multiplicity of what Patrik Svensson calls a digital humanities that is less a tent and more a disaggregated “trading zone” of various interests and disciplines. Instead of a transcendent, disciplinary category, the digital humanities emerges as an imminent set of assemblages and rhizomatic localities — converging in some places, diverging in others.

This panel of short papers intervenes in the discussion of an imminent digital humanities by describing several actual alternate histories of the field. All of the thinkers for this proposed panel have sketched variations on digital humanities history in the past. Steven Jones begins his book on Roberto Busa, for example, with an extended discussion of the “multiple potential continuities” existing beside the mythological figure as providing a possibility for “better historical understanding” (16). While Amy Earhart’s work historicizes digital literary studies in America through the work of the new historicism, Tara McPherson sees it in the screen cultures of media studies, Roger Whitson points to the publics outside academia invested in steampunk and other nineteenth-century sources, and Padmini Ray Murray explores the repurposing practice of jugaad in India. Such alternate histories point not to a denigration of the meaning of the digital humanities as a disciplinary field, but rather describe — as Lori Emerson says about media archaeology — each strand as “one possibility generated out of a heterogeneous past.” Each of the presenters will spend 10 minutes discussing how DH can be historicized using various disciplinary, national, and outer-institutional contexts.

Activism in Digital Humanities: Complicating Community, Technology, and Open Access

Amy Earhart

Much of our history in digital humanities has focused on proving that our work has legitimacy within the academy. As I have argued in other publications, the digital humanities has been critiqued as a regresive field, particularly in terms of its approach to cultural studies, and, at the same time, as a challenge to traditional humanities (“Futures”). Key to this simplistic critique of digital humanities is a representation of the digital humanities as a monolithic structure. As part of a panel which reveals the multiple histories of digital humanities, this paper will chart the alternative history of activism and community/academic partnerships in the digital humanities.

Arguing that critiques of digital humanities are ahistorical, the paper will focus on the connection between activism and community in the early digital humanities. For example, the public/academic focus of early digital humanities work has direct ties to what we now call public digital history. Douglas Seefeldt and William G. Thomas have argued that the future of digital history "invites students and the public into the digital process," yet this is actually not a future goal. It is our past and connects to a long historical interest in digital humanities as activism and a means of creating community partnerships.

Of particular focus, in the paper, are projects that bring scholars inside the academy into partnerships with community groups, such as the early *NativeWeb* or *eBlackStudies*. While such early projects are often viewed as retrograde technologically and often dismissed from our dh genealogy, they offer an alternative history of the way that technologies are used in service of particular fields within the academy. At the same time, such projects are interested in bridging the divide between the academy and the community and serve particular activist agendas. While there are some forms of digital humanities that reject a focus on cultural studies, this branch of digital humanities centers political activism and critiques of race, class, sexuality, and gender within its approach.

The paper will also focus on the way that technology is imagined in the various lineages of digital humanities. In the line of activist projects that the paper examines, technologies are decentralized, often out of the box, and less interested in innovation than in, say, current large corpora data mining projects. Too often "simple" technological projects are dismissed as not digital humanities, even when the theoretical usages of technology in relationship to humanities questions are innovative and forward thinking. Instead of accepting techno progressivism, scholars in digital humanities need to apply the full spectrum of humanities critique to the treatment and use of technology. For example, scholars have a responsibility to address the ways that technological specifications might force western representations of knowledge onto materials of cultural expression that do not use such systems. Projects such as the *Tibetan and Himalayan Library's (THL)* use of TEI/XML provides one example of how we might proceed. The *THL* has considered how the understanding of time might be culturally constructed and, as such, has revised the TEI/XML coding to reflect time from the perspective of the Tibetan culture rather than imposing western understandings of time through technological standards.

The history of activist digital humanities projects reminds us to think about how the exploitation of data is related to historical exploitations of people(s), to reconnect the digital with embodied experience. Mark Turin notes, "archives become more complex when the 'documents' in question are representations of human 'subjects,' as was the case for the ethnographic archives in which we were interested, including photographs, films, sound recordings and field notes on people's lives, their cultures and their practices" (453). Documents are never devoid of embodiment, as we might never use the term exploitation of data without understanding that, eventually, exploitation of data has real impact on individuals and communities. A division of human subjects and documents leads to problematic interactions with those who we are working to digitize. We need to think about how our data embodies experience.

The paper will close by focusing on the way by which ideas of open access are culturally constructed. Activist projects complicate the adage "information wants to be free," reminding digital humanities practitioners that the model of broad 'access' that often motivates western digitization efforts does not apply universally." The complexities of technology as represented by such practitioners are central to digital humanities.

Roberto Busa, S.J., and Humanities Computing: Complicating the Origin Story

Steven Jones

The Jesuit scholar, Roberto Busa, is often called the founder of humanities computing. In fact, starting as early as 1949, he collaborated with IBM to perform experiments using suites of punched-card machines. These punched-card data systems—with their plug-board setups, clacking machinery, and flurries of perforated rectangular cards—were developed for business accounting and tabulating, and adapted for government censuses, defense calculations, archival management, and information processing of all kinds. These systems coexisted for many years with electromechanical calculators and electronic computers, helping to define, delimit, and shape the possibilities for research applications, including humanities research applications like Father Busa's. Because the card systems were eventually connected to electronic computers, they've become part of the story of humanities computing. But in many ways, the first decade of humanities *computing* can more accurately be described as an era of humanities *data processing*—in the historically specific and contextually rich sense of the term.

My historical work on Roberto Busa's data processing has drawn on a key premise of media archaeology: that technology doesn't "evolve," or "descend," in a linear way. As Michel Foucault asserted, genealogy (in the sense he used the term) cannot be figured by strictly logical trees of descent, as in the "evolution of a species." It's a way of viewing events in their "proper dispersion," including the "minute deviations . . . complete reversals—the errors, the false appraisals, and the faulty calculations . . . the exteriority of accidents" that constitute history. When it comes to Busa, so often treated as the "founding father" of humanities computing and digital humanities, one way to complicate the origin myth is to pay attention to the "exteriority of accidents" that shaped the received story, to tell the story slant, as it were, by looking at what Steven Johnson has called the "adjacent possibilities," even the dead ends or paths not taken that nevertheless help us to understand what was done.

One example is the fascinating Microfilm Rapid Selector machine, which Busa briefly considered but from which he swerved away. Based on an experimental design by Vannevar Bush for the famous memex, the prototype was viewed by Busa in operation at the library of the Department of Agriculture in 1949. It offered a competing paradigm (both technically and institutionally) for information processing and retrieval. Or, the large-scale photo-mainframe IBM SSEC, which Busa saw working at IBM in 1949-1952 but was unable to use himself (since it was dedicated to scientific and industrial applications). It nonetheless inspired his thinking about the nature and scale of his linguistic data. Its existence as a kind of adjacent possibility is a useful reminder both of the institutionalization of the "two cultures" of science and the humanities at mid century, and, at the same time, of the artificiality of the categories. Or, take the Dead Sea Scrolls project, which Busa's "lab" undertook but could not complete (and the remnants of which remain in the Busa Archive in Milan), but which revealed some of the limits of the idealized "computerized philology" that Busa was pursuing at the time.

My work on Father Busa, IBM, punched-card machines, and large-scale calculators has been inspired by Geoffrey Rockwell and Stéfan Sinclair, who have called for a media-archaeology approach to the technologies of the mainframe era. I've also drawn on a related approach, platform studies, which looks at individual platforms in their multilayered material particulars. Because media archaeology looks at forgotten or discounted technologies (presumed to be superseded by what has come to dominate the present), and replaces a triumphal narrative of technological progress with messier stories, it can usefully check and complement the laser focus of platform studies. Together, they allow for richer, more detailed views of the changing cultural and historical conditions within which technologies emerge and jostle for prominence.

Theory/Practice: Lessons Learned from Feminist Film Studies

Tara McPherson

This talk investigates possible relationships of theory to practice within digital humanities and media studies and also calls for a politically engaged approach to both fields. It seeks to move beyond the binary framing of the DH slogan, "less yack, more hack," by arguing for a more integrative and dialectical melding of making and critique. In particular, I turn to feminist film studies of the late 1970s to examine an earlier moment in media studies that sought to integrate media production, distribution, theory, and pedagogy toward expressly political ends. In conversation with contemporary feminist scholarship in new materialisms and digital media studies, I argue that practices of making can and should enrich our theoretical and discursive endeavors within feminism.

In a recent article taking up the phrase "less yack, more hack," Claire Warwick helpfully suggests that increased focus might be paid to the qualifiers "less" and "more" rather than to a binary opposition between "yacking" and "hacking" (538). I agree. We can then see yacking and hacking as held within a productive and dialectical relation. To take this line of thinking further, we might not even focus on "less" or "more," as if the relationship between theory and practice can be reduced to balancing a formula. Instead, we might understand the two terms to be tied together in a productive and iterative friction. The tensions between "yack" and "hack" are not, perhaps, all that unique to the digital humanities. They exist across the university in structures that make it hard to combine theory and practice in our curricula, evaluation and promotion structures, disciplinary methodologies, and privileged forms of scholarly output.

As digital humanities scholars have struggled with the right balance of yack and hack, broader debates have emerged about the relationship of theory to practice across the academy. If these tensions have simmered just below the surface of disciplines for much of the twentieth century, then the digital turn has reanimated such debates in new ways in the new millennium. Returning to earlier moments of practice within and beyond the academy can provide valuable lessons for DH today.

The wedding of theory and practice was crucial to the formation of feminist film studies as a field over forty years ago. We see this joining quite literally in the title of key essays such as Claire Johnston's "The Subject of Feminist Film Theory/Practice." The "/" signals a hybrid practice beyond the "and." Published in the journal *Screen* in 1980, the piece reports on the Feminism and Cinema Event held at the 1979 Edinburgh Film Festival. Johnston writes that, "throughout the week, emphasis was placed on the need to locate feminist politics within a conception of film as a social practice, on the dialectic of making and viewing and on film as a process rather than an object" (27). The early history of feminist film theory models a vibrant relationship of making to critique. Many feminist film scholars engaged in a form of inquiry that understood theory and practice to be constitutive of one another. These insights were often born of a deep exploration of the material forms of cinema—explorations enriched by practice. Such work is vitally important terrain for digital humanities, leading us to ask how our machines encode culture in very particular and often damaging ways while also perhaps signaling an enhanced role for artists and designers within DH endeavors.

Decolonising Design: Critical Making and Jugaad in India

Padmini Ray Murray

This talk will cover the establishment of the first Masters-level digital humanities programme in India, as well as a digital humanities research agenda that contextualizes and embeds such work in an Indian environment. Ray Murray will discuss the shift that this unique context generates, in terms of necessarily moving away from modeling such work on paradigms established in Anglo-American institutions, and her work towards the creation of a locally reflexive practice which responds more appropriately to its conditions. Drawing on the work of architectural historian Arindam Dutta, Ray Murray will historicise these arguments, demonstrating how design as a discipline is implicated in the work of colonialism, and how the praxis of critical making (as formulated by thinkers such as Matt Ratto and Garnet Hertz) can contribute both to decolonising design and more broadly, humanities scholarship in India, as well challenging traditional institutional frameworks that are the legacy of colonial education. Ray Murray will demonstrate how critical making is a particularly useful mode of inquiry in a context where digital humanities work is relatively nascent, in order to supplement and inform an emergent narrative of the history of what might be considered digital humanities in India.

Radically different technological and infrastructural conditions as well as historical mean that this narrative diverges from those which underpin established histories of Anglo-American digital humanities, and Ray Murray will explicate on how this difference necessitates alternative methodological approaches in order to reconstruct alternative histories. The work of Jentery Sayers and others at the Maker Lab at the University of Victoria on their cultural kits for history, while emphatically not exercises in replication and more in remediation, and in foregrounding "how the past is interpreted through present conditions, exhibiting history as a collection of refreshed traces, with both loss and gain" often relies on historical material culture such as patent documents, illustrations, artefacts in order to inform their creation, much of which is conserved and made available by Victorian values of empire-building and taxonomic collection. In contrast, the history of indigenous technologies in India is patchy and often obscured by more visible archival material which asserted colonial structures of oppression, complicating the use of a mode of inquiry such as Sayers et al's cultural kits for digital humanities work in India.

In addition, in a country like India, where literacy is still at a premium, design and making privileges the value of other forms of knowledge found in communities, such as crafts or indigenous traditions. Ray Murray will thus demonstrate to how conceiving of critical making in the tradition of practices such as *jugaad*, an indigenous combination of making-do, hacking, and frugal engineering makes for a contextually appropriate intervention in understandings of the digital humanities, and allows for a more politically nuanced view of tools, materials and the conditions of production that have laid the foundations for digital humanities scholarship going forward. In closing, Ray Murray will discuss how contemporary design education privileges "solution-ing", which anticipates a model of consumption rather than co-creation, tracing a trajectory from colonial ambition to neoliberal inevitability—and how digital humanities thinking discourages this mode by with its legacy of interpretation that discourages a one-size-fits-all response. Ray Murray will conclude by asserting the uses of creating a useful methodology to turn the lens of scrutiny upon digital artefacts and activities as well as being observant of different materialities and modalities of knowledge production in order to both historicise and limit the over determined nature of the digital.

Alternate Histories: Steampunk Fandoms and Digital Humanities Publics

Roger Whitson

The digital humanities is often characterized as dedicated to making scholarship publicly accessible. Yet accessibility is only one way to pursue a public digital humanities agenda. Another method leverages the complicated history described by media archaeology to highlight how various publics outside of University settings are already constructing digital humanities projects of their own. Jussi Parikka begins *What is Media Archaeology?* with an extended consideration of steampunk as an exemplary media archaeological practice, arguing that it falls outside of mainstream digital methodologies and is what Deleuze and Guattari call a "nomadic, minor science": a set of quirky hacker techniques whose innovations are appropriated by the more economic powers of the state (qtd. in Parikka 168). As with any manifestation of what Deleuze and Guattari call "royal science," or a hegemonic system relying upon the appropriation of nomadic practices, steampunk creates a tension between such minor sciences and their corporate and academic use. For every fascinating gadget produced by steampunk fans, there are also corporate phenomena like Justin Bieber videos featuring joyless representations of steampunk automatons whose cogs are appropriated only to sell more albums.

This talk explores a set of steampunk projects from fans in order to show how their methodologies constitute an alternate history of the digital humanities rooted in the practice of public hobbyism. One example of this steampunk hobbyist practice is Tim Robinson's 2007 build of a Babbage's *Difference Engine No. 1* from parts manufactured by the toy company Meccano. Robinson says that he was intrigued by the brand's claim to "do something real," and the tactile quality of Meccano parts mediates this sense of reality: the cold metal, the round rivets, the clicking of metal rods as they are moved by other parts. The machine's design is based upon Babbage's first engine and calculates numbers up to four digits and three orders of difference. It is composed of several ratchet wheels, each with 20 teeth and which are covered by printed tape showing numbers from 0 to 9. While visiting Robinson's website, you can find descriptions of his nostalgia for the toy company, which he describes as helping him build "the machines of my youth" — including "astronomical clocks, orreries, looms and other textile machinery [...] and perhaps most enduring, the differential analyzer (and analog computer)."

Robinson's project exists within a wide variety of other steampunk gadgets that express both nostalgia for various parts and fascination with methods of building: from other models of the difference engine, like Andrew Caroll's version created with Lego parts and rubber bands; to the varied projects of *The Steampunk Workshop*'s Jake von Slatt — who rescues available parts from junk yards and repurposes them into workable Steampunk RVs (Recreational Vechicles), Wimshurst Influence Engines, and even a Stroh violin with an amplifying horn and aluminum diaphragm. For me, such projects underscore Matthew Kirschenbaum's argument that hobbyist activities enable the digital humanities to value "the unapologetically small, the uncompromisingly local and particular" ("Ancient" 196). Yet, steampunk hobbyism also enables a different understanding of the role various publics who engage in such activity play in the digital humanities as a field.

Many digital humanities projects envision the public as a homogeneous entity who acts primarily as an audience or — in some cases — a collaborator for what ends up being essentially a scholarly act. The sheer diversity of steampunk fandom, on the other hand, resists such an easy or homogeneous definition. While some aspects of steampunk fandom act, as China Mieville has observed, as forms of nostalgic imperialism; or as Charles Stross claims, as romances with totalitarianism, other fans use steampunk to imagine histories where the Industrial Revolution happened in Africa or China rather than in Europe. Miriam Rocek dresses up as a time-traveling "Steampunk Emma Goldman" and participates in protests like Occupy Wall Street. Lisa Hager, meanwhile, uses her steampunk persona to advocate for gender neutral bathrooms. Such diversity underlines the need to understand how steampunk and the digital humanities communities exist as discrete assemblages, rooted in the politics of the communities practicing them. While this talk will cover mainly hobbyist projects within steampunk fandom, it will contextualize that work with a multiplicity of various local practices. All of these practices, I argue, extend to the digital humanities as a field — which is less a big tent and more a massive assemblage of becoming, branching, and multiplicity.

La culture du réseau sans fil et du partage instantané a profondément remodelé notre conception du monde, ainsi que nos pratiques d'écriture, de lecture et de spectature. L'objectif de cette table ronde est d'examiner quelques projets récents qui cherchent à exploiter et à comprendre ces nouveaux dispositifs.

La question que nous nous posons est avant tout celle des usages des technologies mobiles numériques dans le cadre des pratiques artistiques et littéraires actuelles. Comment les créatrices et les créateurs se servent-ils des médias et dispositifs numériques? De la même façon, comment nous servons-nous des dispositifs numériques comme outils de façonnement d'un discours critique sur les arts et les littératures, de recontextualisation, de mise en scène ? Comment la cohabitation entre les œuvres et les discours critiques peut-elle donner lieu au déploiement d'un imaginaire de la mobilité et de la création numérique? Il ne suffit pas qu'il y ait des technologies pour que des pratiques naissent, encore faut-il des environnements de recherche, de connaissance et de collaboration qui favorisent leur reconnaissance et leur diffusion.

Il s'agira de considérer la mobilité comme condition et facteur de création des œuvres ou comme modalité de réception. Les intervenant-e-s aborderont en ce sens les expressions de cette mobilité sous trois angles complémentaires, à savoir les dispositifs mobiles, les plateformes (Twitter, Periscope, Facebook, Facebook Live, Instagram, Snapchat, Youtube, etc.) et leurs usages et détournements.

Nous interrogerons par exemple la façon dont les plateformes mobiles se posent comme lieux d'exposition. Les internautes deviennent commissaires en ligne, agençant photographies et textes selon des critères de cohérence qui leur sont propres. Instagram ou Tumblr, en tant que plateformes centrées sur l'image, s'imposent comme des espaces parallèles à l'espace muséal où le travail d'association et de rapprochement de l'internaute se fait valoir. Les plateformes mobiles sont également le lieu d'exposition de soi par excellence. Les internautes sont invités à performer une identité projetée et régentée, encore une fois, par une ligne directrice qui révèle des appartenances et des positionnements. Les artistes de groupes marginalisés saisissent notamment cette opportunité pour bâtir des communautés en ligne liées par un discours commun. Ces considérations seront l'occasion d'explorer deux pans de la pratique qui se recoupent par un même principe, soit la mise en scène ou l'exposition en contexte numérique.

Ces questions sont étroitement liées aux enjeux politiques et identitaires en ligne, soulevés par plusieurs créateurs et créatrices. Critiques, les œuvres tendent alors à employer différentes stratégies esthétiques pour rendre compte des rapports de pouvoir, souvent invisibles, qui régissent pourtant le réseau. Nous commenterons à cet effet les œuvres qui détournent les flux du Big Data pour créer des espaces-autres, que ce soit par l'entremise du court-circuit, du piratage, de l'infiltration ou de l'appropriation.

Enfin, plusieurs thèmes et problématiques recoupent l'ensemble des présentations brièvement déclinées ci-dessus, soit l'introduction d'un nouveau rapport au temps et à l'espace, l'adaptation de nos modes de lecture et de spectature et la constitution de communautés de créateurs-rices et de chercheurs-ses.

Thèmes abordés:

1) Plateformes mobiles comme lieux d'exposition
2) Pratiques littéraires d'écriture et de lecture en contexte numérique
3) Parcours littéraires et imaginaires urbains
4) Détournements du big data
5) Représentation des communautés marginalisées en ligne

Description of Session Topic

How can DH regional communities best be cultivated and sustained? This panel explores US-based digital humanities collectives that foster active communities of practice. Regional consortia are a growing phenomenon in US digital humanities, offering opportunities for loosely organized groups of DHers to share workshops, events, datasets, conferences, and news with one another. Such arrangements have the benefits of addressing institutional barriers to DH work and enabling sharing that can help address, at least in a small way, funding and infrastructural inequities that can make it hard for newcomers to begin DH work. According to John Theibault, regional consortia "can be distinguished from, on the one hand, state and national digital humanities groups that organize conferences and edit journals and require paid membership, as well as digital humanities centers located in a single institution or formally constituted groups with explicit criteria for admission, and, on the other hand, not visibly organized interactions in active digital humanities regions, even if those interactions are frequent in practice" (2016). Theibault identified 11 self-organized regional consortia not affiliated with a larger organization such as EADH, mostly in the US. Such consortia can serve an important need in connecting researchers from a range of institutions and building community more expansive than a campus and more localized than a national or international scholarly organization. As Rebecca Frost Davis and Bryan Alexander have pointed out, "large-scale multi-institutional projects aimed at building resources and pooling expertise . . . [can be] constructed to match the needs of both small liberal arts colleges and large research institutions." The building out of regional consortia, then, can help broaden the impact and audience for digital humanities work while simultaneously addressing infrastructural needs and allowing institutions to share complementary strengths.

This panel will consider how a range of regional DH groups have organized their communities, many of them through the free WordPress-based platform Commons In A Box, to build active and lasting communities of DH practice. Presentations will cover the contours and plans of specific regional communities as well as the guidance such examples may offer to academic communities just beginning to organize themselves. Attention will be paid to shared commonalities across regional organizations as well as distinctive areas of focus. Included in the panel will be a discussion of software tools that communities can use to build regional DH organizations, with a particular focus on the Commons In A Box software used by many of the groups represented on the panel. The panel will also delve into the challenges of organizing and sustaining a regional consortium, including rewarding the volunteer labor that such organizations depend upon, raising awareness of the consortium, and developing an appropriate governance model.

Though this panel focuses on US-based regional organizations, it is hoped that the panel will stir conversations on an international level about shared models of community sustenance and infrastructure. Out of this exchange, the panel hopes to build an informal network of regional DH consortia that can serve as the basis for the ongoing development of DH communities.

CBOX Development and NYCDH

Matthew K. Gold

This presentation will discuss the design, implementation, and future plans for Commons In A Box (CBOX), with a particular focus on how it is being used in the NYCDH community to foster community among New York City DH researchers and practitioners. In NYCDH, a CBOX site has been used to create groups around discrete topics such as "Digital Art History," "Librarians In DH," and the "Digital Antiquity Working Group." Each of these groups were started by members of the site and are used, along with larger public groups such as "Announcements," to foster connections across a range of NYC institutions. In recent years, the site has facilitated the planning and implementation of an annual conference that includes a week of workshops on DH subjects offered across the NYC area by a range of institutions, and an annual prize for the best graduate student DH project. The site includes a shared calendar that is populated by members and member institutions, so that it provides a quick sense of DH events in the region.

Commons In A Box is a free software project supported by a grant from the Alfred P. Sloan Foundation and maintained by the Graduate Center of the City University of New York. Commons In A Box has two elements: a plugin manager and a default theme. The plugin manager enforces version dependencies between a collection of WordPress plugins, ensuring that all such plugins work seamlessly and without conflict—a technical innovation for the WordPress plugin ecosystem. For the end-user, the experience of installing Commons In A Box is extremely smooth; upon activating CBOX, the plugin manager automatically performs what would otherwise be dozens of manual steps, including plugin installation, activation, and configuration. The CBOX theme, which is based on the design of the CUNY Academic Commons, can also be installed; when activated, it creates a Commons space that features image sliders, community elements such as lists of members and recently updated blogs in the sidebar, and group-related functionality such as "reply-by-email" group forum functionality that has been crucial to community building on the CUNY Academic Commons. The result, and the key technical innovation of the CBOX project, is the transformation of a complicated set-up and customization procedure into an easy, streamlined installation process. CBOX is currently used by a number of organizations, including the Modern Language Association, NYCDH, Texas DH, Virginia DH, and Florida DH, to build Commons spaces for DH communities.

Under the aegis of an NEH Implementation Grant, Commons In A Box - OpenLab is a new version of CBOX dedicated specifically to teaching and learning, called CBOX-OL. In this presentation, we will describe how integrating a suite of teaching-centered digital tools for content sharing and annotation into the core code of CBOX and bundling it with a core set of DH pedagogical tools ensuring that CBOX-OL communities meet accessibility standards. We will also partner with OER initiatives at partner institutions to create ways of sharing open-access humanities content within and across Commons environments that promote and reinforce sound citation practices. Finally, we have secured a commitment from Reclaim Hosting, a popular hosting service for educational institutions and digital humanities projects, to integrate CBOX-OL into its suite of easily installable software packages. Included in the new version of CBOX will be a set of teaching-related plugins as well as a suite of DH-related WordPress tools in the areas of scholarly communication, such as Braille, which translates English text into Braille; Anthologize, which enables bloggers to create eBooks from their posts; DiRT Tools, which helps community members identify the tools from the DiRT Directory they use; and PressForward, which can be used by teachers to collect content, and then to assign the selection, evaluation, and re-publication of that content with an introduction as an activity to encourage students to connect their classroom discussion with ongoing contemporary debates. All of these plugins will benefit the digital humanities humanities via their potential to enable open learning and exchange, emphasizing scholarship as an open, process-based activity, rather than a closed, solitary one.

Commons spaces don't build themselves; rather, they are cultivated and energized by participation and leadership from members. Technical development lays the foundation on which such work can happen, but the growth, evolution, and sustainability of such platforms require vision, commitment, and resourcefulness from members of the communities where they launch. This presentation will close with a consideration of the ongoing personal, institutional, individual, consortial, and infrastructural support needed to foster and maintain flourishing communities of active practitioners.

The CUNY Academic Commons

Micki Kaufman and Lisa Rhody

The CUNY Academic Commons is an academic network built at the City University of New York (CUNY) by and for faculty, graduate students, administrators, staff, postdocs, and alumni across the 24-campus system. The site serves to foster community and promote scholarship across our twenty-four campuses. With over 7,293 members and well into its seventh year, the Commons continues to evolve as a vibrant space where members connect, create, collaborate, and explore.

As the site has grown and matured, user outreach has become an increasing focus. In addition to webinars and one-to-one engagement with users and administrators of Commons groups, the team has most recently established Commons Faculty Fellowships to assist faculty in setting up Commons sites and customizing the platform to provide the right teaching tool for class needs. In conjunction with CUNY campus Teaching and Learning Centers, these outreach efforts are helping to promote the benefits of the Commons as a teaching tool across the 24 campuses.

A significant focus of the Commons development has been on personalization of the user experience. With the addition of attractive, customizable public profiles, members can now create beautiful online portfolios for their work. The high-impact header section provides an elegant profile synopsis and collapses as one scrolls down the page. Social media icons and website links help connect user profiles to a range of services on the web. Our sophisticated profile builder makes it easy to create an online CV using free-form and specialized widgets designed to highlight positions, education, publications, and interests, and the new RSS feed widget helps members include excerpts of recent posts. Likewise, the addition of Quick Links gives user profiles, blogs and groups customizable shortened links, easy to remember and ideal for business cards and CVs. Using the cuny.is/ URL shortener helps Commons users to personalize their site and to more effectively communicate their relationship to CUNY.

The Commons allows users to create and join as many groups and websites as they want. This allows users to administrate departments, teach classes, discuss and share resources on a selected topic, and connect with people sharing common interests on the Commons. Features of the Commons include the ability to have groups be public, private, or hidden and can include a host of functions including discussion forums, file storage and document collaboration, and rich email integration that allows a more email-driven, 'listserv-like' interaction with the Commons. Sites created by Commons users take many forms including personal blogs, research projects, department, class, event or conference sites, journals, reviews and news commentaries, and photo blogs, and are configurable using hundreds of themes and plugins for a wide range of visual presentations. Users also have free access to the Commons community's WordPress Help group to get help building their sites and managing accessibility.

The Commons also now includes Social Paper, a networked writing environment that enables students to compose and share all forms of their written work across classes, disciplines, semesters, and publics. Likewise, students can browse and comment on the papers of their peers. Unlike many learning management systems or course blogs, Social Paper gives students full control over the sharing settings of each individual piece of writing. Students may choose to share a paper with a professor, a class, a writing group, the public at large, or alternately, keep it private as part of their personal, in-progress, reflective writing portfolio. Additionally, while composing, students can post comments on their writing with questions mentioning other users in order to solicit peer feedback or interest. By giving students a centralized space to manage the totality of their writing, students can easily change privacy settings as they mature as writers and thinkers, develop audiences for their growing body of work, and reflectively build off prior writing.

As the Commons continues to grow, and as its development team continues to release updated versions of Commons In A Box, the site will endeavor to continue serving the needs of faculty, students, administrators and alumni across the 24 CUNY campuses -- and in the process exemplifying how an academic social network can be sustained across a university system with multiple campuses.

Texas Digital Humanities Consortium

Lisa Spiro

Even as digital humanists at Texas colleges and universities are creating significant digital humanities projects, we face common challenges, such as finding collaborators, learning new skills and developing educational programs. In the fall of 2013, Lisa Spiro (Rice), Cameron Buckner (University of Houston), and Laura Mandell (Texas A&M) discussed establishing a statewide digital humanities consortium to connect digital humanists across the state and foster collaborations. The University of Houston hosted the first Texas Digital Humanities Consortium (TxDHC) conference, co-sponsored by Rice and Texas A&M, in April of 2014. At the conference, we held an open business meeting to plan the TxDHC, which attracted 19 participants from colleges and universities across the state. We discussed common needs, including to support faculty, graduate, and undergraduate training in DH; to build community so that members are aware of projects, opportunities and potential collaborators across the state; and to gain access to infrastructure (such as Omeka) for projects (Spiro 2014). To meet these needs, we planned to develop a website, hold an annual peer-reviewed conference, and provide informal opportunities to interact, such as by publicizing visiting speakers at our home institutions. We also explored creating internship opportunities for graduate students and advocating for DH. Rather than establishing formal structures, we decided to operate as a "coalition of the willing," with decision-making by consensus. To gather additional input, TxDHC used an online survey, which had 14 respondents between April and September of 2014. Respondents ranked the following as the leading "high" priorities: foster networking (92.9%); identify researchers in Texas with common interests (71.4%); and facilitate collaborative research (64.3%).

Informed by the input received from the meeting and survey, Spiro set up a founding steering committee (SC) for TxDHC, inviting representatives from Texas universities and colleges to serve. Current SC members include Spiro (chair), Jennifer Hecker (University of Texas), Laura Mandell, Rafia Mirza (UT-Arlington), Laurel Stvan (UT-Arlington), Toniesha Taylor (Prairie View A&M), Andrew Torget (University of North Texas), and Dillon Wackerman (SMU); representatives from Southwestern University and University of Houston have also served on the committee.The Steering Committee meets via video conferencing several times each year to discuss the ongoing development of consortium and events such as conferences and webinars; we also communicate fairly regularly through email. Our mission is to " promote digital research in the humanities disciplines and facilitate interaction amongst researchers working in the digital humanities both within the state, nationally, and internationally" by connecting people, facilitating training and knowledge sharing, and raising the visibility of DH work. Membership in TxDHC is open to anyone who sets up a profile on the organization's website. Currently there are 58 "active" members and 116 members signed up for announcements.

This presentation will explore TxDHC's history, initiatives, challenges and future plans. TxDHC's core activities focus on building community across the state, including through:

- **Our website.** Texas A&M's Initiative for Digital Humanities, Media, and Culture (thanks particularly to the work of former staff member Matthew Christy) installed and hosts the TxDHC's website, using Commons in a Box to encourage collaboration. The website includes member profiles, groups focused on topics such as Training and Metadata Standards, and a calendar. We have also implemented the DiRT Tools plugin to identify tools used by TxDHC members .
- **State-wide conferences.** TxDHC has sponsored two multi-day conferences: its inaugural conference at the University of Houston in 2014 and its second conference at UT Arlington in 2015. While these conferences boasted strong programs, recruiting Texas institutions to host the event has proven challenging, especially since TxDHC lacks resources beyond endorsing the conference, publicizing it, and enlisting steering committee members to assist with it. In 2016, TxDHC shifted to a strategy of partnering with other Texas digital humanities/ digital library conferences to hold post-conference events, avoiding duplication of efforts, making it more convenient for people to attend both events, and taking advantage of cross-publicity. Recently we organized a one-day hybrid unconference/mini-conference following the Texas Conference on Digital Libraries in Austin and a THATCamp following Digital Frontiers in Houston. The mini-conference combined the best of THATCamps and more formal conferences by giving speakers fifteen to twenty minutes to set the context, then devoting the rest of the hour to discussion. While attendance at THATCamp Digital Frontiers was fairly small, the event connected participants from Rice, the University of Houston, UT Arlington, UT Austin, and local museums and explored topics such as creating an introduction to DH course and reviving DH projects.
- **Webinars:** TxDHC runs occasional web-based workshops on topics such as OpenRefine, DPLA, and using tools like Omeka or Hypothes.is in the classroom. To encourage interaction and build community, we employ a video conferencing platform so that participants can see each other's faces, and we try to set aside time at the end of each event for information sharing.

TxDHC faces several challenges:

- **Raising awareness of its existence.** At the recent Digital Frontiers conference, it became clear that many attendees didn't know about TxDHC. The organization is primarily publicized through its events, website, word of mouth, and Twitter, but more outreach to DH groups across the state is needed.
- **Accomplishing its vision with few resources.** Lacking a budget or staff, TxDHC depends on the time and commitment of its hard-working volunteers, particularly its steering committee members. Of course, these volunteers face competing demands on their time, so consortium work is fit in as it can be.
- **Keeping the website updated and encouraging people to make full use of it.** Ideally, members of TxDHC would add events to the calendar and participate more actively in online groups, but those hopes haven't yet materialized. Focused outreach may increase participation.
- **Developing a governance model**. Initially we operated without clearly defined roles, which allowed for flexibility but also meant that members didn't necessarily get recognized for their contributions and weren't tied to particular responsibilities. Moreover, we would like to develop a more coherent and transparent method for bringing new members onto the steering committee and rolling senior members off. In December of 2015, members of the steering committee came together for a day-long retreat at Rice University, where we discussed the need to spread out the work and ensure that all are recognized for their contributions and sketched out more defined roles. We are working on bylaws to formalize the organization's operations and are in the process of implementing plans made at the retreat. At the same time, many SC members are sympathetic to the lightweight organizational approach taken by NYCDH, which several Steering Committee members learned about during a recent presentation by Alex Gil and Kimon Keramidas at Digital Frontiers 2016. Focusing on partnerships and fostering communication across Texas DH organizations seems like a sound strategy for a small, all-volunteer organization like TxDHC.
- **Dealing with geographical distance:** Since Texas is the second largest state in the US, it can be difficult to connect people across such a significant distance. To cope with this distance, we have organized state-wide events and online gatherings, but we also hope to encourage members to use the website to promote events and activities within a particular city or region within Texas.

By working together, regional consortia can learn from each other, explore developing common infrastructure (as we have already benefited from CUNY's work on

Commons in a Box), and facilitate broader collaborations around research and teaching.

Florida Digital Humanities Consortium

Scot French

My presentation will explore the opportunities and challenges involved in creating a geographically extended, self-governing regional consortium (FLDH/Florida Digital Humanities Consortium) that depends, for its intellectual labor and technology support infrastructure, on academic institutional sponsorship while promoting free, open access to academic networks and DH resources.

Founded at THATCamp Florida 2014, FLDH's mission "is to provide a platform for studying and discussing digital tools, methods, and pedagogies as well as for educating teachers, faculty, and the public about the multiple, interdisciplinary ways humanities research and computing impact our world. It meets annually to identify issues of interest and to set goals for future collaboration and digital humanities research." At present the group has 12 institutional members, ranging from large research institutions to small liberal arts colleges: University of Florida (Gainesville), University of Central Florida (Orlando), Florida State University (Tallahassee), University of South Florida (Tampa), University of Miami, Florida International University (Miami), Rollins College (Winter Park), New College of Florida (Sarasota), Florida Southern College (Lakeland), Eckerd College (St. Petersburg), and the Florida Humanities Council. Inspired by NYCDH and the CUNY Academic Commons, group organizers adopted the Commons In a Box (CBOX) academic commons social networking platform as a virtual space in which to foster community and share resources.

An internal grant from the University of Central Florida funded an organizational meeting in Orlando at which representatives of participating schools and the Florida Humanities Council established an Executive Council with two representatives from each institution. A five-member elected Steering Committee drafted a mission statement and set of by-laws, established short- and long-term goals, and began planning for two major initiatives: Hosting HASTAC17 in Orlando (scheduled for November 2017) and submitting a proposal to host a southeast regional pre-conference workshop on visualization tools through the National Endowment for the Humanities' Institutes for Advanced Topics in the Humanities. Working on these initiatives has placed new demands on FLDH's leadership structure, and prompted a shift from volunteer initiative to a more active chair and working group/subcommittee organizational framework.

To date, all of our discussions about how best to build and organize our statewide/regional consortium have been internal to the group. We seek to expand the conversation to representatives of similar groups, particularly those using the CBOX platform developed by Matthew K. Gold and his project team at CUNY. Out of this exchange we hope to build an informal network of regional DH consortia for purposes of information sharing that can be expanded and formalized as needed.

This paper/presentation will raise issues of general interest to the DH community and of particular concern to members of the FLDH Executive Council (which I chair) and Steering Committee (on which I serve as a founding member).

- **Leadership/Self-Governance Structures**. What sorts of leadership/self-governance structures do regional DH consortia employ to ensure broad-based institutional representation, inclusion of diverse views, and transparency in setting group agendas and policies?
- **Academic Commons Activity**. What strategies or best practices might regional consortia adopt to build community and generate sustained activity on CBOX or other academic commons platforms? How can participating institutions most effectively contribute to the development of CBOX or similar platforms, with an eye toward enhanced functionality and customization?
- **Staffing/Program Support.** Is it feasible for participating institutions to "share" staff in support of mutually beneficial program and projects? What roles might digital humanities center staff, graduate research assistants, or postdoctoral research/ teaching fellows play in fostering a regionwide DH community and providing training for interested faculty and students? Is state, national, international, or foundation funding available in support of such regional collaborations?
- **Service/"Invisible Work."** To what extent, if at all, is the volunteer work of consortia officers (such as FLDH Executive Council/Steering Committee members) recognized as valued service within their respective institutions? Could regional consortia have a role in documenting and validating the contributions of active members seeking promotion and tenure or other paths to career advancement?
- **Geographic Distance/Virtual vs. Face-to-Face Meetings.** Are webinars and Google Hangouts an adequate substitute for face-to-face meetings and workshops? How might regional consortia spanning large geographic areas (such as Florida and Texas) create more funded opportunities for travel to consortia-sponsored conferences/meetings? What options are available both within and across member institutions for fundraising in support of travel?

As chair of the FLDH Executive Council and a member of the Steering Committee I will conduct an informal member survey to solicit other potential topics for discussion during this session. Ideas generated by this panel will be shared with the Executive Council and serve as the basis for discussion and action at an FLDH organizational meeting during the Orlando HASTAC conference in November 2017.

SD|DH: Building and Strengthening DH Teaching and Learning through a Regional Network

Erin Glass and Jessica Pressman

How can DH regional networks work to spread resources to underserved student populations, foster digital literacy and confidence in educators without DH institutional support, and strengthen local, humanistic forms of social advocacy? This presentation will focus on the development and future plans of the San Diego Digital Humanities (SD|DH) regional network, a collective comprised of faculty (and some staff and graduate students) from seven different local higher education institutions ranging from a R1 university to community colleges. While San Diego is not prominently known for humanities research—let alone DH—we recognize that its location on the border of Mexico, and the diverse student body of its institutions, make it an exceptionally rich site for socially-engaged, participatory forms of DH activity. By pooling resources, expertise, experience, perspectives, and moral support, SD|DH embraces the power of diversity as our chief value.

SD|DH has been working together for the last three years to share experiences and resources, plan events, apply for funding, and seek collegial support for our endeavors. We work from different institutional situations and relationships to digital humanities: a campus pursuing a grass-roots and ground-up approach to digital humanities research and teaching but lacking funding for institutional infrastructure, a campus administration wanting to implement digital humanities from a top-down structure, and a campus successfully implementing digital humanities projects within a specific department but lacking the leadership to build out from there. We have been successful in different ways at different campuses, but we now have a full-blown DH initiative at SDSU and an emerging program at USD, and we continue to use our individual campus efforts to bolster the region

Our first goal in forming SD|DH was to assess the barriers to implementing DH across a wide spectrum of institutions and diverse student populations, and develop work-around strategies for implementing DH by drawing upon the resources of multiple institutions within a single region. From the start, these efforts have been voluntary, but we were able to expand our efforts and visibility with the generous support of a National Endowment for the Humanities Level I Digital Start Up Grant for our project “Building and Strengthening Digital Humanities through a Regional Network.” This grant supported a series of workshops that focused on distributing DH to institutions and student populations usually left out of DH. It also helped encourage educators to explore new DH techniques for teaching within the safety net of a supportive community. Educators engaged in a wide range of DH methods such as text analysis and game design as well as DH-inspired techniques to creative re-imagine uses of everyday software and tools for pedagogical purposes. We met several times throughout the year to discuss challenges and successes, share expertise, and brainstorm new possible projects.

In this presentation, we will discuss our methods for developing and facilitating these workshops and pedagogical engagements as well as some of the relevant issues concerning coordination, labor, administrative support, technical resources, and transportation. We will also share lessons learned throughout our experience thus far and suggest protocols that could potentially be re-used and re-purposed by other institutions. Finally, we will argue for the need to collectively and creatively communicate the value of multi-institutional collaboration to administrators in order to increase administrators’ receptivity to these efforts going forward.

In addition to discussing projects already carried out, we would like to share our plans for moving forward. As part of deepening and expanding our community’s ties, SD|DH is working towards launching a multi-institutional digital commons powered by Commons in a Box (CBOX) hosted at UCSD. While some SD|DH campuses could ostensibly run and host their own CBOX we have decided to experiment with creating a single commons for our community so that all participating SD|DH institutions can take advantage of the many affordances of CBOX. We are planning to use this Commons in multiple ways. First, we will use it to facilitate communications for the SD|DH group as a list serv, events calendar, member directory, and showcase of SD|DH projects. However, we will also invite all students, faculty, and staff of SD|DH institutions to use the Commons for networking across institutions, building websites related to research and teaching (for any discipline), and creating interest groups that cut across disciplines and institutions. Finally, we also hope to implement Social Paper, a collaborative writing tool developed at The CUNY Graduate Center for CBOX through the generous support of a NEH Digital Start Up Grant. We are currently discussing the possibility of designing multi-institutional synchronous courses that will engage students in thinking through the role of collaboration in their respective disciplines by collaborating with students outside of their institutions through Social Paper.

Beyond Access: Critical Catalog Constructions

Molly Hardy
mhardy@mwa.org
American Antiquarian Society, United States of America

Dawn Childress
dchildress@library.ucla.edu
UC Los Angeles, United States of America

Paige Morgan
paige.c.morgan@gmail.com
University of Miami, United States of America

This panel explores the use of digital, rare book catalogs as platforms for collaboration and as sources of data to uncover patterns of book production and to offer new insights into the sociology of texts. Extractions from and additions to bibliographic data extend the catalog beyond its original use as a point of access and discovery. The use of catalogs as sources of bibliographic big data as well as the use of platforms that enable bibliographic record annotation allow us to reimagine the catalog's trajectories of creation and utility. Considering the genealogy of the catalog, the panel will examine how research practices have both informed and been informed by catalogs since their inception and how the work of bibliography is reimagined in the catalog. Focusing on how limitations and aporia in the catalog can lead to critical making in the digital age, the panel will show how digital uses of the catalog currently enable mindful interrogation of catalog data and catalog making as well as consider possibilities for expanded use of rare book catalog data in the future. This consideration of the rare book catalog as a digital humanities project invites reassessment of legacy information architecture as well as the many hands that built the bibliographic structures on which so much of the work of the digital humanities rests.

In "Towards Speculative Catalogs," Dawn Childress will open with a discussion of the transformative promise of the digital as we reconstruct catalogs in new forms and formats. To provide context for critical catalog constructions more broadly, Childress will highlight how bibliographies and catalogs have served as source material for research beyond that of points of access in both pre- and post-DH contexts, as well as consider how digital humanities use cases might differ from more analog approaches, whether qualitative or quantitative. In addressing these questions, Childress will explore the promise of applying current and emerging tools and standards (such as linked data, IIIF, PCDM, etc.) to the practice of interrogating bibliographic and catalog data. Childress will suggest how we might leverage these systems to record and analyze lacunae, erasures, and bias in capturing the bibliographic record and, drawing on Bethany Nowviskie's notion of speculative collections, how these systems might support active reframing and interrogation by users.

In "'The Technology of Shared Cataloging': A Retrospective," Molly O'Hagan Hardy will build on Childress's remarks through a close look at the creation and re-creation of two rare book union catalogs: the English Short Title Catalog (ESTC) and the North American Imprints Program (NAIP). In 1981, in a Bibliographic Society of America Symposium from which the title of Hardy's paper takes its name, William Todd wrote, "Perhaps we do not yet fully appreciate the situation, now rapidly materializing, whereby computers converse with each other in any mode, while the rest of us, mere mortals, stand mute before them." Remarks like this, which abound in the excitement and trepidation expressed during the emergence of these rare book union catalogs, echo a similar exuberance and hesitancy around the transformation from MARC to linked data models. Examining what "machine readable" meant then and means now, Hardy will draw parallels between the current conversation around BIBFRAME and other such initiatives and those early efforts led by Robin Alston and Marcus McCorison to amass large amounts of special collections' catalog data. She will then examine what it was these catalogs set out to capture and in what ways this work is being reimagined in the linked open data environment. She will do this through a close look at the American Antiquarian Society's Printers' File linked data project and its reliance on LCNAF and VIAF to merge MARC data with BIBFRAME. Ultimately, she will consider how such initiatives necessitate the reimagining of library and scholarly work, so those working on both sides of the reference desk are not left to "stand mute" before their creations. Hardy will point to examples of innovative uses of rare book catalog data for digital humanities projects. Such uses, Hardy will show, not only prove efficient and effective means of generating data, but they also productively unearth biases inherent in any information system.

Paige Morgan will conclude our presentations with "Searching For Common Ground: Modeling Bibliographic Data in Library and DH Contexts," in which she will present the results of a survey of data use in DH projects examining the projects' use and presentation of library data (including bibliographic data and data presented in digital collections platforms). This survey will focus on

- whether each project includes bibliographic references;
- how much granular detail any bibliographic references include,
- whether or not such data is presented in the format of a specific model, and
- the presence or absence of links to specific copies, whether in library or digital archive catalogs (such as HathiTrust, the ESTC, paywalled collections (ECCO, EEBO, etc.), or websites like Google Books and Project Gutenberg).

Gathering this data will allow Morgan to look for common priorities in the project creators' use of library data; and to identify some of the assumptions that digital humanities has made about libraries and the bibliographic information that they produce. She will use the DH project survey data as the basis for a comparison with bibliographic ontologies (such as FRBRoo, BIBFRAME, Schema.org, and BIBO), and literature on challenges and best practices in bibliographic data modeling. Morgan will look for intersections, missed connections, and opportunities between digital humanities and cataloging work; and will consider how assumptions made in digital humanities elide the complexity and ongoing negotiations in the production of bibliographic data. In these projects, what drives the decisions to model (or not model) bibliographic data? How do the priorities of DH practitioners differ from those of library-based data creators? The increasing development of off-the-shelf tools, and the gradual growth of infrastructure for learning digital humanities skills and accessing data means that in many ways, it is possible for DHers, both new and experienced, to do more than before. However, increased access to materials and resources does not mean that the efforts of DH and library data communities will automatically complement each other. In FRBR, Before & After, Karen Coyle observes that library personnel working with data "have made little change in our approach to subject analysis in the last half-century, possibly because there isn't a clear direction for improving this aspect of our work." This paper will argue that similar ambiguities exist around the use of bibliographic data in DH projects, and that the apparent common ground of bibliographic data use is more complex than it appears.

Decolonizing Methodologies: Recovery and Access Amidst the Ruins

Christy Hyman

Brian Rosenblum
brianlee@ku.edu
University of Kansas, United States of America

"It was as if these matters of objective and hard science provided an oasis for folks who did not want to clutter sharp, disciplined, methodical philosophy with considerations of gender, race and class-determined facts of life" (Earhart 2012, pg. 5).

"There is something truly soul-destroying in the repeated discursive erasure of vulnerable identities whether in the media, on the street, in the classroom, or in the legislative chamber" (Wright 2015, 264).

Recent instances involving the desecration of hallowed structures erected in remembrance of turbulent periods in the U.S. solidify the need for a call to action to enact historical recovery amidst the "ruins." The ruins include the marginalization of subaltern agents within grand historical narratives, the propensity of the academy to view historical purveyors of intellectual thought as overwhelmingly European, and the invisibility of subaltern agents in traditional and digital archives. Sites of subaltern experience drift in and out of the historical record often leaving no tangible signifiers to how these events inform the racialized, gendered, and class based systems of power which influenced many of the negotiations that subaltern agents contended with in initiating action and decision-making in an oppressive world. Historical recovery in the digital humanities play a vital role in enabling users with access to new knowledge as well as helping to shape meaning and interpretation of the cataclysmic phenomena embedded within its mediums. Anelise Shrout's call for **history from below** is essential to creating digital content which enables accessibility and users potentiality of increased awareness of the historical underpinnings related to structural inequality- Shrout rightly declares that digital methodologies are ideally suited for these interventions (Shrout 2016).

This panel offers several approaches to historical recovery through showcasing digital projects which utilize technologies designed to foreground subaltern histories while preserving contextual integrity. We bring together three approaches- geospatial, alternate reality gaming, and online digital collections for a conversation that will highlight the methods and values involved in the digitization, visualization, user interaction and theoretical analysis of content. Our panel consists of scholars who've developed interdisciplinary approaches in their area of inquiry emphasizing historical recovery as a focal point of their research: Anelise Shrout's presentation explores the Digital Almshouse Project and argues for the importance of digital humanists bringing together new archival methods with the old while critically reading archival silences as opportunities for further recovery and analysis. Christy Hyman's presentation highlights the ways that GIS recovers subaltern experience through the struggles of enslaved runaways in antebellum eastern North Carolina using the digital narrative The Oak of Jerusalem: Flight, Refuge, and Reconnaissance in the Great Dismal Swamp Region. Hilary Green's paper examines digital collections alongside pedagogical approaches that introduce students to centering historically subaltern actors using intersectional strategies and inclusive pedagogies. Kathryn Kaczmarek-Frew illuminates opportunities available with alternate reality games in building adolescent's historical knowledge by showcasing The Tessera, a game inspiring teens to take on the roles of real life scientists, programmers, and artists as they solve conceptual challenges while immersing themselves in a storyworld. Finally, Nishani Frazier discusses the conflictual relationship between the academy and the digital, the changing role of the scholar/expert, the importance of community in historical production, and the balance needed between recovery and shared authority.

In doing so, this panel promises to stimulate a lively and engaging discussion that will be informative to digital humanists of many fields. By presenting content and methods that connect subaltern humanity to recovery methods within the digital this panel helps forge the way for future work in gaining access to a more public facing scholarship that foregrounds the marginalized stories, agents, and actors into the digital humanities.

All panelists have agreed to participate.

Rehumanizing Data: Digital Methods Against Archival Violence

Anelise Shrout

Some of the most interesting historical subjects left only the faintest traces in the archive (Shrout 2016). When people of color, enslaved people, immigrants or women appear at all, it is often as commodified figures, ancillaries to those in power, or as undifferentiated masses of undesirable bodies. Scholars have recently begun to note that the archival silencing of these marginalized voices is not merely oversight, but rather, as Marisa Fuentes argues, a kind of epistemic violence. (Fuentes 2016). The absence of these subjects, these scholars note, is a feature, rather than a bug.

This presentation proposes a set of digital humanities practices that explicitly work against the structures that kept those voices silent in the first place. It uses Digital Almshouse Project, a dataset of Irish immigrant who emigrated to North America to the port of New York in the 1840s. These men and women subsequently fell ill, became destitute, or were simply seen to be incompatible with New York's public spaces. They were identified by public officials and sent (often forcibly) to New York's Bellevue Almshouse – the only public health site that offered social services to people fleeing famine. In the process they were transformed; their diseases (a category which included the social maladies "recent emigrant" and "destitute"), their children (who they would often be separated from inside the almshouse) and the spaces of confinement to which they were sent transmuted from individual experience into bureaucratic data.

This presentation uses the Digital Almshouse Project to rehumanize nineteenth-century immigrants. In doing so, it illustrates the ways in which scholars can bring "big data" analysis to bear on silenced voices; can use data visualization to resurrect archival ghosts; and can deploy quantitative analysis to give weight to historical actors long since written out of history. It asks that data-driven digital humanists pay particular attention to historical actors whose bodies were quantified and commodified, and who were in the process stripped of markers of humanity. Finally, it highlights historical bureaucratic spaces in which immigrants were able to enact agency, while also laying bare the ways in which the carceral state has used data to dehumanize marginalized subjects.

The methods discussed in this presentation have roots in "history from below," the "new social history" and cliometrics of the 1970s and 1980 (Gallman 1977, Shammas 1977, Darnton, 1984). Together, these methods sought to resurrect the stories of "people with no history," by reconstructing their quotidian experiences. However, the subjects of these studies tended to only be relatively marginalized – they included (white, male) artisans, (white, male) voters, and (white) women property holders. There have been various resurgences and developments in these methods in the intervening four decades. These include practices of reading archives "against the grain" to get at the unstated assumptions that historical actors made about those they held power over. They also include theoretical approaches that advocate the reading of silences to understand those whose voices were intentionally obscured by official recorders and gatekeepers (Trouillot 1995, Bastian 2003, Drake 2016). This presentation argues that we must bring together new archival methods and the old cliometrics; that we must critically read archival silences while simultaneously using regression models to coerce meaning from our data; that we should think about the motives of historical data creators, while we also use dataviz to trace historical actors' pathways through hostile spaces. This presentation aims to not only theorize digital approaches to marginalized people, but to present a concrete toolkit for beginning to center the voices and experiences of those marginalized historical subjects.

GIS as a Phenomenological Bridge to Experience: Deep Mapping the Enslaved Runaways of Eastern North Carolina

Christy Hyman

My paper examines African American efforts toward cultural and political assertion in geographies of domination, specifically the Great Dismal Swamp area and adjacent communities in North Carolina during the long nineteenth century. Building on the work of archaeologists, historians, and novelists, my presentation reimagines space as it relates to the experiences of enslaved runaways and laborers who were exposed to the Great Dismal Swamp. I argue that the proximity of the Great Dismal Swamp increased the incidence of flight despite the danger and overall inhospitable nature of that landscape. In examining African Americans who navigated the landscapes of trauma inherent in the institution of slavery within the eastern North Carolina region, this study sheds light on the common values, aspirations, culture, and economic systems of a people relegated to the margins of society. This investigation into the spatial dimensions of flight within the Great Dismal Swamp, with the use of historical primary sources, generates new knowledge about the enslaved experience. This approach highlights and analyzes space itself with a view to uncovering the social relationships embedded in it.

Focusing on enslaved runaways' proximity to waterways and the natural environment within the Great Dismal Swamp, this project uses Esri Story Maps to tell the digital narrative of The Oak of Jerusalem: Flight Refuge and Reconnaissance in the Great Dismal Swamp Region, a project containing maps with narrative text, images, and multimedia content. The data contained within this digital narrative was gathered from nineteenth-century North Carolina newspapers such as the Cape Fear Mercury, Carolina Observer, Edenton Gazette, and many others which provided information on the destinations and distributions of enslaved runaways, including frequency distribution of enslaved runaways by month of disappearance and gender specificity. In terms of the Great Dismal Swamp landscape, content will include remote sensing data, forest dynamics of the swamp, soil characteristics, and animal species such as amphibians, reptiles and mammals. Taking these physical properties of space together with the historical descriptions of enslaved runaway ads and cross-referencing this information with textual descriptions in the enslaved narratives written by Moses Grandy and Harriet Jacobs, a complete reality of what was at stake for an enslaved person to run away emerges. Because these seemingly disparate elements of space (and the social relationships embedded within) are scattered across the archival landscape, my project brings all these things together in one setting.

Geospatial technologies are central to this study because of the ways that GIS can be a phenomenological bridge between subaltern experience and measurable qualities of the Great Dismal Swamp landscape. Using geoprocessing methods employed with ArcGis tools a cost surface was developed to investigate the ways enslaved people appropriated the landscape into areas of refuge and reconnaissance and eventual escape. A cost surface is a geospatial technique based on measuring the effort it takes to cross a landscape area. Data contained within a DEM (Digital Elevation Model) representing the Great Dismal Swamp landscape allows for this form of spatial analysis. The cost surface can thus be used to find the path between identified points along the surface with the least amount of effort. In measuring "cost" for enslaved people during the antebellum era four sets of variables were attained:

1. Cumulative distance- total distance to travel from one place to another
2. Duration or travel time- total time to travel from one place to another
3. Energetic expenditures or calories- total calories expended to travel from one place to another
4. Experiential/Cultural- abstract measures such as visibility between sites, social distance, and spheres of influence.

Through Moses Grandy and Harriet Jacob's dynamic reminiscences, the extant data on enslaved runaways near the Great Dismal Swamp, and the physical properties of space within the Great Dismal Swamp landscape the shadowy foundations of how the Great Dismal Swamp functioned as a quasi-dystopian landscape for enslaved people is recovered. Ultimately the swamp embodied the promise of freedom as a site of possible refuge, but also the horrors of the slavery regime itself.

Disrupting the Archive: Intersectionality and the Integration of the Digital Humanities in the Classroom

Hilary Green

In today's classroom, gender and race scholars strive to provide students with a breadth of scholarship that represent the social, cultural, and political experiences that define both the American and global experiences. For scholar-activists working at large southern PWIs, the politicized tensions present in society today stemming from difficult racial pasts, and potential efforts at truth and reconciliation, all compel us to reconsider what sources will most impact students' understanding of these difficult subjects. To effectively educate students, instructors do well to expose them to diverse historical documents, assignments, and approaches. Digital humanities offer new opportunities and challenges as eloquently expressed by Tara McPhersons' "Why Are the Digital Humanities So White? or Thinking the Histories of Race and Computation." This conference presentation will explore how to use engaging assignments (spatial analysis projects using Carto and documentary history projects) and digital archive collections to introduce students to a variety of sources using intersectional approaches and inclusive pedagogies that are used to critically engage students from diverse backgrounds.

Digital archive collections offer scholars a valuable service by providing an online platform to publish digital archives. Managing content is no easy task and scholars as well as institutions have to find resources and time to develop their sites in a way that encourages curiosity, usability, and scholarly utility.

Colored Conventions is an excellent archival addition to the digital humanities. Colored Convention's purpose deserves quoting in full:

> "This project seeks to not only learn about the lives of these mostly male delegates, the places where they met and the social networks that they created but to also account for the crucial work done by Black women in the broader social networks that made these conventions possible."

ColoredConventions.org endeavors to transform teaching and learning about this historic collective organizing effort—and about the many leaders and places involved in it—bringing them to digital life for a new generation of undergraduate and graduate students and researchers across disciplines, for high school teachers, and for community members interested in the history of church, educational and entrepreneurial engagement" (Colored Convention, 2015).

As evidenced by Colored Convention's purpose their aims are to reach a broad audience which refers to the public humanities focus of the project. The site has teaching aids, curriculum guides, as well as the primary source documents that have been recovered from relative obscurity. What Colored Conventions does is recover an entire archive of action performed by antebellum era African Americans taking initiative to move closer to freedom.

In the context of pedagogy, intersectionality asks students to think beyond narrow binaries that overdetermine contemporary discourse on identity and power (Risam, 2016). For particularly vulnerable populations who have historically experienced economic disadvantages the disciplines under the humanities does not at first glance offer a high upward mobility. How then can the humanities compete and attract a diverse array of students as well as engage scholars toward its humanistic offerings? In engaging digital archive collections centering marginalized people's histories it becomes necessary to interrogate the archive, recover subaltern experience, and reimagine new approaches to historical interpretation. In doing these things fresh perspectives unfold as the humanities discipline as a whole is invigorated with scholarly interest. Students and scholars alike find new purpose in the humanities. These new questions coupled with the innovation in toolmaking within the digital invite a wealth of promise through intersectional approaches and inclusive pedagogies.

Casting our Lights Before: Immersion as Access in The Tessera ARG

Kathryn Kaczmarek-Frew

"They say that coming events cast their shadows before. May they not sometimes cast their lights before?" -- Ada Lovelace

Computer science and the technology industry are often regarded as the bastion of white men. However, there is a movement in popular culture to recover and make visible the contributions of women and minorities, from the major motion picture Hidden Figures to the AMC series Halt and Catch Fire. Still more active methods can be used to connect today's youth to the realities of the past and the promise of the future. Alternate reality games provide a unique opportunity to combine historical knowledge and skill-building in a way that pervades into daily life. In my presentation, I will show how our alternate reality game The Tessera invites teen players to develop a more nuanced understanding of computer history while demonstrating that they already possess the computational thinking skills to make a future in the industry accessible to them.

Developed as a collaboration between the University of Maryland, Brigham Young University, and the Computer History Museum under a grant from the National Science Foundation, The Tessera ARG uses the genre of Victorian gothic realism and the trope of haunting to think about the influence of the past on the present. The narrative focuses on the ghost of Ada Lovelace recruiting teenage players, particularly those from demographics underrepresented in STEM disciplines, to join her secret society known as The Tessera in their fight against an even more mysterious destructive force known as S. Racing against time, players complete a series of collaborative puzzles emphasizing computational thinking skills such as pattern recognition, decomposition (breaking down a problem into smaller steps), algorithmic design, and data representation. By emphasizing the STEAM values of innovation and creativity as the key to progress, The Tessera helps players recognize that they already do computational thinking and that they can have a future in the technology industry.

Like many ARGs, The Tessera distributes its narrative across several media, presenting different opportunities for immersion. The Tessera: Ghostly Tracks is a real-life experience in the Computer History Museum, where classes will divide into groups to use digital clues and physical artifacts in the Revolution exhibit to solve computational thinking puzzles and discover which famous figures from computer history are haunting the museum. Players will experience a highly embodied sense of immersion as they move around the exhibit and manipulate props to solve the puzzles, such as decoding the message etched on the top of a chessboard or using a code to open the six padlocks on an "enchanted" crate, releasing the ghosts from the museum. In contrast, The Tessera: Light in the Shadows is an online game in which Ada guides players through the ruins of a decaying Victorian pub into the Tessera stronghold of Horsley Towers to create new innovations inspired by key inventions from history (such as the telegraph, the metric system, and Wi-Fi) to thwart S's destruction. The online game requires imaginative recentering to immerse the player within the storyworld, aided by the use of first person perspective, tension-inducing time limits, and the invitation to write themselves into the narrative through the public-facing wiki (Ryan 1992). While the goal is for players' personal investment in the Tessera's struggle to translate into learning, I'm interested in studying how the different avenues of immersion in the two experiences influence players, not only in their interest in the game content but also their self-perception of their computational thinking skills. This research will allow future game designers to think about how different kinds of simulations (physical, digital, augmented, and virtual) can be used for historical reconstruction to help players best access the realities of buried pasts.

Power to the People: Recovery and Shared Authority in Civil Right Movement Digital Work

Nishani Frazier

African American Studies, public history, and oral history methodologies play central roles in the recovery of fairly unknown aspects of civil rights movement history. However, this merger also required a philosophical embrace of community engagement, power sharing, and open access during historical production. Though these ideals may fit within digital humanities, historical practice among academics is at odds with this approach. This talk discusses the conflictual relationship between the academic and digital, the changing role of the scholar/expert, the importance of community in historical production, and the balance needed between recovery and shared authority.

Theorizing African American Public History Through the Digital Humanities

Expanding public understanding about the history of the Congress on Racial Equality community organization and economic development through access to primary sources, teacher resources, and mapping is the resource cornerstone within this project. It acts to recover a little known aspect about CORE and its relationship to racial uplift and economic development while providing access for future scholars and other interested persons. This process is a model for intersecting African American scholarship and digital humanities.

The digital representation Harambee City illustrates this philosophy through:

1. Broad accessibility
2. Providing a second layer of learning through open access to primary sources and teacher lesson plans
3. Knowledge sharing - commentary/exchange on the website
4. Community organization training

The aim of this project is to promulgate further inquiry within historical study of the Civil Rights Movement as well as contemporary interventions concerning social justice issues (Frazier 2016). Following on Jessica Marie Johnson's call to action regarding the urgent need for the digital humanities to engage with society's "marginalized or discriminated against" this project endeavors to fulfill historical as well as justice imperatives needed within the digital humanities by examining civil rights movement history not commonly centered (Dinsman 2016).

Notes

1. The Old Ashburn School, an historic African American schoolhouse in Loudoun County, Virginia was vandalized with swastikas on October 1, 2016, another incident occurred in Tallahatchie County, Mississippi where the memorial sign of murdered African American teenager Emmett Till was found riddled with bullets on October 15, 2016. As far as the Pacific Northwest in Portland, Oregon in September of 2016 the statue of Vera Katz, a progressive politician and former mayor of the city was sprayed hateful epithets. Katz is of Jewish Menshevik origin and her family fled Nazi controlled Germany in 1933.

Introduction

Papers including the topic "Networks, Relationships, Graphs" have comprised roughly 10% of submissions to ADHO's annual conference for the past 4 years - a sizable portion, to be sure, but one that has remained roughly consistent in that time (Weingart, 2015). "Networks" are, in the abstract, familiar to humanities scholars devoted to studying complex relationships. This potential is alluring, but advanced network analytical techniques are challenging to implement and interpret. And overly complex visualizations have attracted derogation from some scholars, deriding visually-impressive but uninterpretable graphs as "hairballs."

This roundtable will take up crucial questions: What kinds of data, questions and interpretive techniques are appropriate for network analysis? How does the disciplinary skillset of the humanist researcher determine, enable or limit effective network analysis? To what extent does the use of data visualization serve to surface, or submerge, essential knowledge about the data? How should scholars in the digital humanities navigate the intense methodological demands of network science? How should such scholarship be evaluated, peer-reviewed, taught, and studied? In the face of these many challenges, what are the futures of networks in DH?

Network Sources / Network Evidence

Why transform our research sources into networks? For some projects, the simple reframing of evidence as a network visualization provides a sufficiently novel perspective to pose more precise research questions and to isolate specific avenues for more research. For research fundamentally about network structures and dynamics, more advanced techniques, including simulation and quantitative hypothesis testing, are required to produce valuable results.

Which path to take may depend on one's sources. Some sources are naturally transformed to networks: correspondence from one individual to another (Winterer, 2012; Ahnert and Ahnert, 2015), for example, or kinship relations. (Jenkins et al., 2013) But less obvious sources may also be seen as networks, such as characters co-occurring in a plot, or documents connected by shared topics. The abstracting and filtering effect of network analysis can also be powerfully applied to illuminate how sources themselves interact to construct knowledge of subjects (Kim, 2013).

How can we encourage more creative thinking about transforming sources (from collections, archives, texts, objects, and more) into networks? When is “basic” visualization productive by itself? Where are complex methods like agent-based simulation or predictive modeling best used? How can network analysis be used to illuminate power imbalances within the scholarly infrastructure? What are strategies for dealing with known unknowns (and unknown unknowns!) in network research, and how can we visualize these missing data?

Disciplinary relationships: Complexity science, humanities, and DH

Examples of the “network” or “graph” idiom, whether actually visualized or merely referenced within a text, can be found in citations well predating modern-day tools for network analysis. They are numerous in sociology (Freeman, 2004), but also in the history of art (Barr Jr, 1936), anthropology (Gell, 1998; Hage & Harary, 1983; Foster, 1969), geography (Bertin, 1967), and economics (Koenig et al., 1979), among others. The idea of the network is a seductive one for humanists who wish to study the multilayered web of interactions between any number of agents (authors, texts, readers, artists, artworks, viewers, patrons), in order to discern how those interactions produce structure and meaning all their own. To do so, however, scholars must grapple with guidelines for expressing assumptions, formulating hypotheses, and gathering and testing evidence using a language of network theory and sociology that can seem alien, if not inimical (Galloway and Thacker, 2007). How have humanities scholars navigated this challenge when using network analysis?

Compounding this effort is the rapid expansion of network and complexity science in its own right. This rapid evolution challenges humanists who would adopt some of these methods for their research. Can a single scholar can find their way without formal partnership with a collaborating network scientist? This raises issues particularly for peer review: How are these papers evaluated between their methodological and their content disciplines?

Network visualization

As with its determination and preparation, visualizing humanities network data in a comprehensible manner is an inherently interdisciplinary task that requires a knowledge of the academic domain, rigorous archival and data management work, and an effective engagement with visual design practices. The proliferating use of visualization tools to represent network data in the digital humanities demonstrate both the potential and the difficulty of this undertaking. The immense complexities of the human connections that network visualizations represent and the probabilistic mathematics that distribute its nodes combine to confound and defy consistent interpretation. Basic technical constraints of dimension, visual design traditions, and a relentless drive for legibility all further reduce, constrain, or even determine the possible interpretations of a dataset from a diagram.

What can humanities researchers engaged in the active process of network visualization do to make informed and effective computational, interpretive, aesthetic and practical decisions? In what cases is the beleaguered “hairball” still a productive or generative approach, in spite of the difficulty it can pose to interpretation? What other alternatives exist? How can the tools, design traditions and/or algorithms currently in use, as well as the introduction of new approaches, dimensions and technologies enhance the power of a network visualization to express and communicate essential understandings about humanities datasets?

Networks and Interactivity

How could new dynamic interactions with network visualization help us better understand and explore our data? With the rise of data journalism and in-browser apps, network visualizations are increasingly interactive, using animations and dynamic features to visualize additional dimensions. Such interactivity can help further an argument, and encourage the user to engage with the data. But, how sustainable and accessible are these visualizations? The long-term viability of these network visualizations depends on continued support, from updating code libraries to adapting to new browser requirements. Moreover, interactivity can be too demanding for slow internet connections, while also complicating workflows for both print and online publication. Added interactivity may also foreground style over substantive engagement with research questions.

What is the relationship of these interactive graphs to their textual explications? How can we design interactive visualizations for multiple modalities and bandwidths? How can digital humanists determine when interactivity is furthering their network analysis? How might interactive network analysis leverage the insights of social annotation tools to analyze metadata on users’ interactions with network visualizations, or utilize more immersive digital experiences, such as virtual or augmented reality?

Access to network methods and tools

All of these challenges intersect with how we teach network analysis and how the scientists teach themselves. The algorithmic transformations of network analysis are not easily accessible, and present a major barrier, particularly to those without any background in data analysis or programming. Those network analysis tools that are accessible to newcomers - and are thus frequently taught in short-term DH workshops - privilege the visualization of networks while largely concealing the behind-the-scenes work of network metrics calculation.

As with computational text analysis, it is simply beyond the scope of graduate programs in the humanities to take on complete responsibility for training its students in network analysis methods (Underwood, 2014). What strategies in mainstreaming computational textual analysis within DH (e.g. the emergence of dedicated "text labs" at several institutions) could be used to produce more substantive work in DH? What failures should be avoided? Where does network analysis in DH diverge so much from computational text analysis that entirely new strategies need to be considered? Moreover, how can practitioners of network analysis in DH make their research understandable and accessible to a larger audience?

Introduction

This panel reports on the open, shareable, and reproducible workflow methodology for digital humanities research developed by the 4Humanities.org "WhatEvery1Says" (WE1S) project. WE1S is topic modeling a large corpus of articles related to the humanities in newspapers, magazines, and other media sources in the U.S., U.K., and Canada from 1981 on. While the panel presents WE1S's conceptual goals and prototype experiments in using outcomes in humanities advocacy, its focus is on the technical and interpretive workflow developed by the project for humanities-oriented data work. WE1S's *manifest system* for data provenance and workflow management, its *virtual workspace manager* for integrated, containerized data manipulation and processing, and its *interpretation protocol* for how humans read topic models suggest a generalizable open approach based not on particular technologies and methods but on annotated methods. Moreover, there is a philosophical fit between such an approach and the public-facing goals of the WE1S project. WE1S is about opening public culture to view through analytics, while its DH methodology is about opening up scholarly expertise itself through shareable, transparent processes not locked into technically complex, pre-established, or large-scale research frameworks.

Project Research and Advocacy Goals

WE1S uses topic modeling to explore the idea of "the humanities" in public discourse. A complex concept of the kind that Peter de Bolla treated in his 2013 *The Architecture of Concepts* (his main example: "human rights"), "the humanities" as they are perceived are both tightly bunched in academic disciplines and broadly dispersed in extra-academic domains. Discussion focused on "the humanities crisis," "the decline in humanities majors," etc. creates flash points in the discourse. Yet the overall heat map of articles about the humanities, WE1S discovers, also extends into vast stretches of warm or cool discussion about humanities subjects intricately interwoven into the background of other domains of social life. Even articles so seemingly unremarkable (yet fully remarkable when we think about it) as an obituary or wedding announcement can mention the humanities as part of their *donnée*. WE1S seeks to open to view this whole conceptual architecture of "the humanities" as it exists in robust, living relation with culture at large.

Project Methodological Goals

Due to the lack of widely shared technical conventions and appropriate scholarly and publishing practices, today it is very difficult for a DH scholar to answer with documentation such questions as: *Where did you get those thousands of works in your corpus? Where did the metadata come from? What steps did you take to prepare and process the material? How many variations did you try? Where in the process was it critical for there to be "humans in the loop"?* The WE1S project addresses a growing need for ways to share and reproduce data-workflow in digital humanities research in order to make DH comparable to "open science" (see Bare, 2014). Indeed, data-intensive work in the sciences offers an especially good paradigm because of the degree to which it makes workflow and provenance management itself a thoughtful research field (i.e., research *about*, and not just tools for, managing workflow and provenance) (e.g., see Gil et al., 2007; and Garijo et al., 2012). The WE1S project is developing a technical framework that explores how the digital humanities can evolve similar, but also necessarily different, *humanities*-adapted standards of openness, shareability, and reproducibility. What amount of data and metadata, in what detail, at which processing stages, with what accompanying scripts, and so on, should be shared to support rich and persuasive scholarly discourse based on digital humanities research in the future? How will the criteria of "reproducibility, replication, and generalizability" (on the different shades of meaning of these terms in the sciences, see Bollen et al., 2015) join more traditional ideas of excellence in the humanities (e.g., "critical rigor") in the various contexts of collecting, curation, exhibition, editing, analysis, interpretation, and other work?

Overview

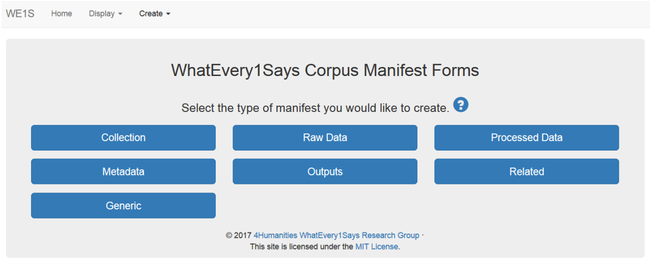
Alan Liu

WE1S explores public thought about the humanities, especially as mediated in journalistic articles that stage a dialogic relation between leaders in government, business, universities, the arts, and others with citizens. The project's end goal is to use such research to guide humanities advocacy. But rather than create a one-off project, the WE1S group has developed a robust technical and interpretive methodology comparable (though customized for DH) to scientific data workflow management systems (e.g., Apache Taverna, Kepler, Wings), provenance tracking systems (e.g., ProvONE), and similar schemes (see Gil et al., 2007; and Bose and Frew, 2005).

Manifest System for Data Provenance and Workflow Management

Scott Kleinman

The WE1S manifest schema uses a JSON Schema-based model to produce "manifests" that document the provenance of articles studied by WE1S as well as later transformations of the data, tying together scripts, stop word lists, outputs, visualizations, etc. used in project work. Manifests make the workflow transparent and facilitate on-the-fly reiterations or adjustments--e.g., staging a subset of the WE1S corpus for topic modeling or defining variant numbers of topics. Manifests are human-readable JSON files that are highly interoperable with other systems; they can be used programmatically to drive scripts or to crosswalk information to other workflow tools or metadata frameworks. The WE1S workflow management system uses the manifest schema to generate web forms, enabling non-technical users to create and query manifests, which are stored using the same JSON-like format in its MongoDB database. The system is easy to deploy and can be adapted for other humanities research projects simply by modifying the manifest schema.



WhatEvery1Says Corpus Manifest Forms

Virtual Workspace Manager for Integrated, Containerized Data Manipulation and Processing

Jeremy Douglass

To address a range of computing demands from geographically distributed participants, the WE1S Workspace Manager facilitates open, reproducible DH research through a defined computing platform, a shareable online environment, integrated customizable workflows, and on-demand publishing of results. Tools for topic modeling workflows are configured on a virtual machine (a Docker container). Open data science notebooks (iPython / Jupyter) are the interface. Project templates are collections of notebooks (Python, R) chained into flows. Each new data exploration flow customizes a template, imports manifest data (from the WE1S manifest system), builds a topic model (Mallet), generates a visual browser (Andrew Goldstone's dfr-browser), publishes the browser to an interactive website, and packages a project for download and offline viewing. WE1S hosts a shared workspace online; it also runs on a laptop. Design and implementation of this virtualized, integrated workflow environment may be relevant to other DH projects, and is consonant with the philosophy of such other online or containerized integrated systems as Lexos or DH Box designed to make advanced DH research environments accessible.

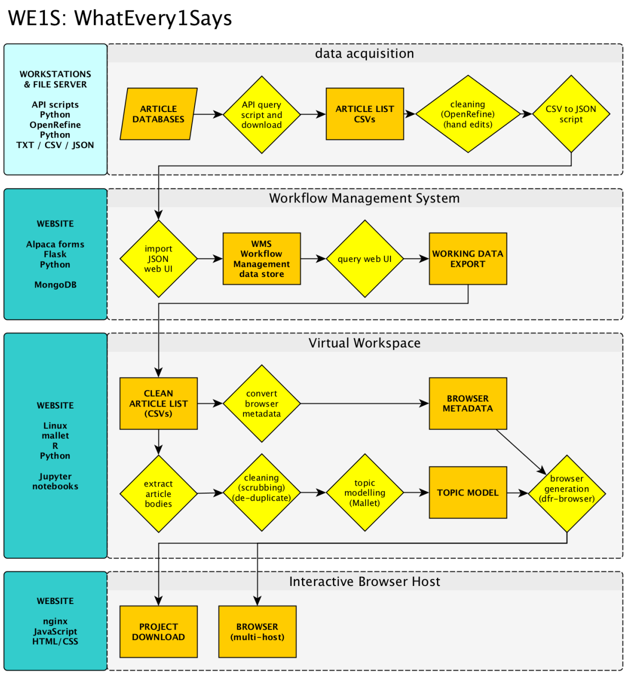

Fig. 2 Architecture of WE1S virtual workspace manager for integrated topic-modeling and visualization as implemented in a Docker virtual machine.

Constructing a "Random" Comparison Corpus

Lindsay Thomas

In public discourse, there are no natural boundaries between what does and does not count as "humanities-related" discussion. The humanities, for example, can appear in both precise and general ways: as a focal topic, as part of arts and culture, in particular forms (such as literature), as part of social and ethical concerns, as part of the biographies or obituaries of individuals, etc. Indeed, it may be that one feature of the humanities is their capacity to forge multiple links between tightly focused and general themes. There is thus no pre-definable "control corpus" of public discussion on the humanities that can serve as ground truth for WE1S's topic modeling experiments. WE1S is thus using a sampled, "random" corpus as a snapshot of the larger, unclosed set of media articles to assist in exploring by contrast what articles can sensibly be defined as "humanities-specific." Doing so not only constitutes a novel approach to topic modeling in the digital humanities; it also reveals intriguing issues about the philosophy behind statistical randomization (see Holland, 1986). This part of the panel discusses the "random" corpus WE1S created, its use within the WE1S project workflow, and includes theoretical reflections on incorporating methodology borrowed from the sciences and social sciences in DH work.

"Interpretation Protocol" for Topic Models.

Ashley Champagne

One of the needs in DH research is a for way to declare not just technical but *interpretive* workflows so that they can be shared, reproduced, and evolved by the research community. In the case of DH topic model studies, for instance, rarely are there transparent descriptions of the interpretive assumptions, steps, and iterations needed to decide how many topics to seek, what topics are interesting, how the topic model guides the human interpreter back to specific articles for examination (and vice versa), and how groups of researchers collaborate in using a topic model to generate hypotheses or come to conclusions. WE1S has created an initial declaration of its topic-model interpretation process that defines step-by-step interactions between machine learning and human interpretation/collaboration (e.g., when in the process humans convene to interpret a topic model; what outputs, visualizations, and secondary algorithmic products such as clusterings are used; how humans discuss a topic model; how topic models and interpretive acts are iterated; etc.). The goal is to make it possible for the larger DH community to improve or vary the topic-model interpretation process in open, shareable ways.

Prototyping How the WE1S Project Can Guide Humanities Advocacy

Jamal Russell

When WE1S has completed its topic models and interpretive studies, it will produce a public-facing site allowing others to explore the models and follow links to the original articles. But how can the project fulfill its ultimate ambition of guiding humanities advocacy? This final part of the panel reports on a unique early experiment in applying WE1S research. In 2016-17, a funded group of undergraduates studied sample articles from the WE1S corpus under the guidance of the project's topic models. They wrote a white paper on their findings with recommendations for humanities advocacy. And they created practical advocacy projects based on those recommendations. Using this concrete example as a springboard, the panel concludes by reflecting on the relationship between interpreting topic models and creating publicly accessible narratives about the humanities.

Overview

Jean Guy Meunier and Louis Chartrand

Many DH projects call upon computer tools for descriptive and analytic purposes: lexicon statistics, concordances, parsers, descriptive statistics, classifications, topic modeling, annotations, automatic summarization, visualization tools, etc. They have been mainly applied to literary, political, journalistic, or otherwise mediatic corpuses. However, less work has been done on philosophical corpuses, or corpuses that have been tailored for the ends of philosophical investigation.

Computational approaches specialized for highly theoretical and abstract texts have proved their efficiency in various domains, particularly in those pertaining to the encoding, curation and presentation of textual data (e.g. digitization, web publishing, authorship analyses, etc.). These successes open avenues for more complex tools and methods to study linguistic features which are not directly observable, such as narratives, themes and concepts.

Concepts, in particular, constitute a key issue, given, on one hand, the polysemy of the concept of concept, and, on the other hand, its widespread use in philosophy and other disciplines. A conceptual analysis is a process through which we decompose and thus elucidate the meaning of a concept. While it is traditionally practiced from the armchair, concepts' meanings are reflected in the texts where they are expressed. As such, the development of methods and approaches to computer-assisted conceptual analysis of texts (CACAT) has the potential to make conceptual analysis more precise, more reliable, more exhaustive and more inclusive.

These new challenges call for an appropriation of modern computational tools which have demonstrated their potential at discovering such entities for natural language processing. The last two decades have seen important developments in computational linguistics and in machine learning which have enabled researchers to detect and manipulate various complex features of textual data. Complex objects such as entities, events, topics, arguments, or syntactic and discourse relations can now be detected and studied. Progress in modelling and learning approaches from fields like probabilistic modeling and neural networks have made it possible to represent complex representations between various latent and explicit textual features, and to learn them in efficient ways. Because they capture different aspects of concepts, including those which appear to be latent or implicit, the innovations could open new and exciting horizons for conceptual analysis.

In order to exploit this potential, digital humanists must participate in the conception of the aforementioned innovations. The humanities have problems and conceptual tools of their own, which differ from those of computer scientists, and, as such, ought to be enunciated and translated into tasks for algorithms to fulfill. On the other hand, computational approaches to conceptual analysis pose specific problems, which must be addressed as new methods are developed: indeterminacy of the nature of a concept and of the method of analysis, complexity in the relation between and among concepts, diversity of interpretations, incertitude in the evaluation schemes, limited set of computation tools to explore conceptual structures, shallowness of visualization tools, etc. These difficulties call for work from social scientists and humanists.

Our aim in this session is to give an overview of the challenges, avenues and opportunities that are shaping CACAT's development. Each paper plays a specific role within this session, so that information in one paper may serve as context for another. Jean-Guy Meunier's paper reviews the challenges facing CACAT, serving as context for the papers that follow. Mathieu Valette's paper (which will be moved to second place) expands on this topic. Drawing on the study of concept formation in philosophy of science, he offers a criticism on the concept of concept, proposes an alternative and draws the implications for the relationship between concepts and their concrete expressions in texts. In working to bridge the gap between the philosophical conceptual analysis in texts and modern techniques of computational linguistics, these two papers work from the conceptual analysis pole. The following two papers, by Louis Chartrand and Jackie Cheung, work from the computational linguistic pole, presenting models and techniques which have the potential of addressing the challenges of CACAT. The final paper, by Marie-Noëlle Bayle, is a recent application of CACAT that exemplifies its potential in discovering implicit dimensions to a concept.

Modelling Computer assisted conceptual analysis in text (CACAT)

Jean-Guy Meunier

Conceptual analysis paradigms

In many fields of scientific research, be they social sciences, natural sciences or even professional practices, abstract or highly theoretical concepts are explored to discover their content and deepen the knowledge they embed. However, there is no consensus on the nature of a concept or on the methodology to analyze them. For example, how would one proceed in analyzing the concept of Evolution in Darwin's writings? Three radically different paradigms parameterize the methodology: philosophical, linguistic and cognitive.

In the philosophical paradigm, concepts are identified to the meaning of predicative words. For some, their analysis aims at finding the conditions (necessary, sufficient, fuzzy, etc.) under which these words refer to objects, events or actions in a possible or actual world. For others, analysis consists mainly of identifying the sense or intention of these words as related to the epistemic or metaphysical conditions for their understanding. Finally, for some others, an analysis should consider the use and context (linguistic, social or other) of these words. Hence, in this philosophical paradigm, conceptual analysis becomes a sort of logicopragmatic analysis of the meaning of words. In our Darwin example, this paradigm would therefore ask what are the meaning conditions of the word evolution when Darwin uses it.

In the linguistic paradigm, concepts are also related to the meaning of words. For the Saussurian structuralists a concept is the core meaning embedded in the structure of the signified (le signifié) of words. For the neo-structuralists, the generativists and the cognitivists, a concept is also equated to the semantic content of predicative linguistic expression, and meaning is understood as a complex set of semantic properties (features, relations, frames, nets, etc.,) underlying isolated words or their position in sentences and discourse. Here, conceptual analysis becomes identified with classical semantic analysis of words. In Darwin's works, the analysis would explore the semantics properties of the English word evolution: for instance, it would study its lexical content, its synonyms, its topics, is semantic nets, etc.

In the cognitive paradigm, concepts are the results of cognitive or mental operations. For psychology, they are seen as a sort of cognitive categorization. For the analytical and hermeneutic traditions of philosophy of mind, they are mental states or world representations. Conceptual analysis consists then in exploring how semiotic or linguistic forms embed categories, intentions, conceptual spaces, beliefs, mental states, Weltanschauung, etc. Hence conceptual analysis bears resemblance to an exploration of cognitive operations or states: representing, categorizing, reasoning, argumenting, entailing, etc. In our analysis of Darwin, this cognitive paradigm would focus the analysis on the mental operations underlying the meaning of evolution. How is this category of mental representation acquired, built reasoned on, argued, etc.?

Choosing a paradigmatic methodology for analyzing concept is difficult, then, because not one of them is canonical. Conceptual analysis becomes an even more acute problem when computations are introduced in the methodology. The level of complexity of the task is so high that is not obvious how a computer assisted conceptual analysis of text (CACAT) project can be realized. Should it be computer-tool-driven or model-driven?

Tool driven approaches

The first type of approach is tool-driven. Once a methodology inspired by one of the paradigms presented above is chosen, its practitioners use some computer programs already built and inserts them in appropriate moments of the analysis procedure. Many computer tools for this task actually exist.

A first set of tools focuses on the lexical expressions of a concept. The most classical ones are concordancers, collocation and lexical analysers, taggers, etc. These tools explore the lexical properties and contexts of one or a few canonical predicates, expressing the specific concept to be analyzed. The limits of these types of tools lie in their underlying design hypothesis: a conceptual content is to be explored through specific canonical expressions. Such a hypothesis restricts the exploration of the conceptual content to one or a specific number of predicates. This is problematic, for as we know, concepts can be expressed in language in a myriad of ways. For example, it would be very problematic to restrict Darwin's concept of evolution to the analysis of the word evolution alone. Secondly, they may produce results that are larger than the original text. This is the case of the concordance of the concept of Esse in the Thomas Indexicus. Finally, sometimes, the opposite happens. These tools may deliver only a fraction of the overall textual segments or word collocations whose content is pertinent. For instance, in Darwin only uses a few dozen times the lexical form evolution. Hence concordance, collocation, etc. on such a small sample are not very fruitful for a conceptual analysis.

A second set of tools highly influenced by classical AI approaches focuses on natural language processing (NLP). These tools are sensitive to various meaning aspects of words, such as their semantic definition, their encyclopedic, pragmatic discursive content, etc. They promise to deliver finer results for a conceptual analysis. But these tools also have limits. Their underlying hypothesis is that these semantic, pragmatic and encyclopedic information added in the grammar and the lexicon will enhance the exploration of conceptual content. Unfortunately, the added information has often been collected from common and ordinary semantic knowledge of shared language usages. Such tools will then often tend to identify already known properties belonging to this common information about the lexical conceptual word under inquiry. And most of the time, it will ignore the properties that precisely are the one that are specific to the concepts analyzed mainly when they are original, and belong to a reflexive, creative literary or reflexive discursive process, etc. These semantic properties would not be part of the common doxastic conceptual content. For instance, a philosophy scholar using such types of tools would not be very satisfied in discovering that Darwin's concept of evolution is a name meaning an action of the type change and applied to the object: natural species.

Recently, a last set of tools that are more mathematically grounded, such as neural net and Bayesian classification, vector semantics, machine learning, deep learning, etc., have become appealing and are used in language processing, They can process large data and learn semantic information by themselves. But like the other set of tools they have their limits. First, they are nor readily usable. They are in fact very complex algorithms, and are not easily mastered by humanities scholars. Secondly, their lack of traceability becomes a major obstacle when applied to large and theoretical textual data where results become difficult to evaluate. Thirdly, they seem more successful for information retrieval applications than for digging into deep conceptual content. For the moment, we are not sure that how they can effectively assist conceptual analysis.

From these remarks, it does not seem to us that conceptual analysis can only be a serendipity tool-driven approach. The results produced by these tools have not yet convinced the scholarly community that practices expert conceptual analysis.

Model driven approaches

The second type of approach is model-driven. Recent philosophers of science such as Morgan and Morrison (1999), Giere, (1999), Leonelli (2007) for instance, see science as a building models process where models are heuristic means for describing, explaining and understanding reality. And Mc Carthy (1999), has seen this modelling approach as a means of better understanding digital humanities interpretative projects. For our part, we explore this hypothesis and see CACAT as type of scientific inquiry where various models are used as intermediaries for understanding the analysis of highly theoretical and abstract concepts. In this perspective, we distinguish four types of models: conceptual, formal, computational and experimental.

A conceptual model defines parameters for identifying, explaining and understanding the properties and structure of linguistic items expressing conceptual content. A formal model translates certain aspects of a conceptual model in some controlled formal language that describes or identifies properties and relations of these conceptual expressions. A computational model translates some formal expressions of the formal model into algorithms and programs. Finally, an experimental model designs implementation of these formal models in a concrete computer where the analysis can be simulated and ultimately evaluated in correspondence to the other models.

In a concrete procedure, all these models interact and can be modified and adjusted. This allows the inquiry to be controllable and repeatable. It has been our own experience that, if a computer assisted conceptual analysis project is to be successful it must construct at least these four models. A CACAT project cannot bypass these models and their interactions.

Designing these models, their interactions and their experimentation to see CACAT as a scientific endeavour and not just computer gadget exploration. But each model is not built easily. And nothing comes smoothly. They are part of the research process. And much work must be done to clarify the conceptual, formal, computational and experimental models pertinent for a successful and pertinent conceptual analysis.

Digital epistemology for concept analysis

Mathieu Valette

In the humanities, theory is most of the time outlined with texts: papers, books, conference presentations, lectures etc. we claim that the scientist is first a reader and a text producer. This textuality is so ordinary that it is almost invisible, and, as such, not considered as an object of science. Moreover, theories are read as synchronic systems, or even achronic systems, depending on their specific purposes (describing one fact, explaining one phenomenon...). Scientists appropriate models and concepts like tools; they have to know their function and how to manipulate them, but they do not care about knowing practical details of their enunciation. In fact, they ignore them, more or less. They find such details embarrassing, because they make concept borders fuzzy: lexicons, glossaries, and also handbooks, as they extract the concepts from their context, and standardise the definitions, creating an illusion of stability and tangibility. But concept textuality necessarily has an incidence, not only on interpretation, but also on theorisation. If the scientist is a text producer, then theorisation is the construction of meaning. Theorisation is forced by enunciation, and scientific works, beyond their materiality, can be considered as text.

The textual aspect of scientific works had been noticed by those in Europe looking at epistemological culture. In this respect, French philosopher Michel Foucault's works, in the 1960s, must be acknowledged (see e.g. Foucault 1969). Foucault put in place a philological analysis of discourse centred on the combination and evolution on specific discursive structures. His purpose is, firstly, to recognize "discursive formations", i.e. stabilized relations, regularities between objects, types of speech act, concepts and topics; and, secondly, to recognise breakpoints in idea system history. Foucault followed the example of some of his famous predecessors, such as Gaston Bachelard, Georges Canguilhem and Martial Gueroult. Bachelard's notion of Epistemological break, or Canguilhem's notion of concept shifts shows, for instance, that the history of a concept is not that of its increasing rationality and refinement, but that of the different fields in which they have been designed and validated. What we will call digital epistemology is a linguistic approach to this style of French epistemology.

Our topic is the study of scientific texts using, on the one hand, corpus linguistics tools which have been developed over the 40 last years and, on the other hand, a linguistic methodology (see Rastier 2009, Valette 2003). Thus, our purpose is to develop tools and methodology Foucault did not have, among other reasons because some textual phenomena—as, for example, lexicon evolution, which depends on the reader's subjectivity—are invisible to a classical philological analysis. Concept emergence, concepts' individual and inter-related evolutions, the appropriation of a specific thematic, palinode, etc. constitute further examples. We do not adopt the logician's position, considering that conceptualization is a linguistic phenomenon with its own construction rules linked to a particular function of language. Neither do we ignore the psychological, social and interactional reasons of the development of concepts. Firstly, we consider that textuality—i.e. the constraints of the textual layout, formulations, be they constraints of syntactic, semantic, lexical or related discursive traditions (including genres and speech)—plays a major role in concept formation. Secondly, we do not consider texts only as resources to mine and extract terminological and conceptual material, but as archives, or, in other word, as the objective tracks of the process of creating concepts.

In essence, we focus here on concept emergence considered as the result of a slow and gradual stabilisation of contextual semantic feature. Drawing on recent critical readings of Saussure's semiology (see Rastier 2015), we propose to consider a concept as a stabilized semantic form; that is, as a combination of semantic features (or semes) mainly inherited from various contexts in which it has occurred. Eventually, we link concept design with text production rather than identification of items in a general ontology (Valette 2010).

Topic models for conceptual analysis

Louis Chartrand

The last two decades have seen the rise of topic models in natural language processing (NLP). From the early successes of Latent Semantic Analysis, which decomposes datasets into "conceptual" dimensions, the introduction of probabilistic and generative models have enabled the discovery of underlying structures that condition the lexicon of a text. Those structures, in turn, are used to construct meaningful representations of corpuses and documents, and have proven fruitful in improving performances in many NLP tasks.

Those tools have interesting potential for the Digital Humanities, as they discover entities which are, on one hand, robust features of textual data, and, on the other hand, easily representable and interpretable by humans. For instance, topics may help in tasks such as categorizing documents or selecting a relevant sub-corpus for analysis. However, once topics are represented using the words to which they are likely to be associated, they can also be used to make sense of what a set of textual segments are about, or to visualize the evolution of discourse in a corpus through time. As such, topics have interesting potential when it comes to representing textual data and improving our analyses of it.

In this presentation, some prominent topics models—LSA, LDA and DTM—will be presented and contrasted, and their potential uses for Digital Humanities will be discussed.

Latent Semantic Analysis (LSA)

Introduced by Deerwester et al. (1990), LSA used tools from linear algebra, in particular singular vector decomposition, to transform the representation of text segments in the form of word counts to a representation in the form of participation to "concepts", or semantic dimensions.

As words give us a good idea of what a text is about, it is common practice in text mining to represent text segments by counting its words. A document containing "apple", "orange" and "pear" a high number of times each is likely to talk about fruits. And if multiple documents share the same words, they are likely to share common topics. However, this approach does not fare well with synonyms, which it does not recognize.

The LSA uses co-occurrence in word uses to synthesize the word-count representations into more compact semantic dimensions. As synonyms tend to have the same cooccurents, they also tend to participate to the same semantic dimensions. As a result, the new representation is closer to a semantic representation than was the word-count representation, hence the name "Latent Semantic Analysis".

Latent Dirichlet Allocation (LDA)

While LSA still is part of every NLP reputable toolset, it falls short in at least two key aspects. Firstly, its semantic dimensions are hard to read for a human: from a list of its most prominent words, it is usually hard to give a satisfying interpretation of what a semantic dimension is about (Chang et al. 2009). Secondly, it has no clear hypothesis as to how text is structured. On one hand, this makes it harder to explain semantic dimensions in terms of linguistics, psychology or discourse analysis. On the other, it means that LSA gets only part of the picture, and better algorithms with additional assumptions might produce better semantic dimensions.

Latent Dirichlet Allocation (Blei et al. 2003) is a probabilistic models which attempts to address this latter issue, and ends up addressing the former as well. It supposes that in a corpus, there is a certain number of topics, which, when activated, make it more or less likely for specific words to be present. Thus, when someone writes a document, LDA assumes that she selects a certain restricted number of topics, which in term condition which words will be found in the document. Using this assumption and an arbitrary number of topics, the algorithm infers the most likely list of topics, and their most likely assignments to documents.

As such, it produces once again a representation of documents or text segments from word counts, but in terms of topics rather than more abstract conceptual dimensions. The words most likely to be present when a given topic is activated are often visibly related, either semantically or because they participate in a transparent narrative. As such, they are easily read by a human interpreter, and can be used to give a sense of what documents, sub-corpuses or textual segments are about.

Dynamic Topic Models (DTM)

Another boon of LDA is that its probabilistic model can be modified account for particularities of the corpus, or to model features that we want to study in particular. For example, if we have a corpus that spans across decades, we might expect topics to evolve with time, as society and culture change.

To model this, the algorithm devised by Blei & Lafferty (2006) uses a corpus split in time slices (say, per year) and topics are split accordingly, such that topic 1 at time 1 is different from topic 1 at time 2. Then, a Markov assumption is enacted on the time series: topic 1 at time 1 conditions topic 1 at time 2, which conditions topic 1 at time 3, etc. This gives topics the freedom to evolve, while enforcing a certain degree of conservatism.

Using this, one can not only track topics more efficiently, but also see the evolution of topics across time.

What is a topic?

What is it, however, that we are talking about when we speak of LSA's conceptual dimensions or LDA's topics? Can it be equated with the notion of TOPIC that we encounter in discourse analysis, for instance?

While there are a variety of definitions for words such as "topic" and "theme", most agree that a topic is what a text is about (Rimmon-Kenan, 1995). On this score, LDA's topic does seem to agree with the common notion of TOPIC: a word list representing a LDA topic is read as a representation of what the textual data is about (Blei, 2013). Furthermore, the information the probabilistic model captures is the one that is redundant across a number of text segments. As such, it highlights words and concepts which keep coming back as they put in relation with various entities in sentences. In other words, textual discourse and narratives are being sewn around them.

On the other hand, humans tend to make slightly different representations of topics compared to machines (Chang 2010), more readily constructing topics around concepts and thus providing sparser (more compact) representations. As Chang suggests, this might be because humans build these representations using general domain knowledge, whereas topic models try to infer this knowledge from word distributions. This seems to tell us that we should understand LDA topics as indicators, or reconstructed traces, of the topics that underlie a text, but not as true representation of topics themselves.

Using topic models in conceptual analysis

As Chang's 2010 experiment suggest, topics entertain special relation with concepts, as a topic tends to be associated with a restricted number of concepts which are expressed very often in the text.

As such, topic models' potential in representing textual data can be exploited to discover associations that are likely to be useful to conceptual analysis and other philosophical analyses. For instance, it can help the analyst identify the most important parts of a corpus, and those that can be discarded. They can also be leveraged to build representations of the contexts in which the concept of interest appears, thus giving a sense of the topics with which it is associated. Using DTM, one can also get a sense of the evolution of a concept within a diachronic corpus. Beyond discovery of new informations concerning a concept's expression in a corpus, topic models can be useful to test some association, as the structures they uncover are relatively robust.

That said, as the DTM model shows, topic models can be used in a large variety of use cases, as their model can be expanded to take into account a corpus' metadata and thus open new and innovative avenues for conceptual analysis and the Digital Humanities in general.

Unsupervised natural language processing for conceptual analysis of events

Jackie Chi Kit Cheung

In unsupervised machine learning, an algorithm is trained to discover regularities in data without access to human-provided labels. Such techniques can be useful in conceptual analysis of text, in cases where we do not have or want to impose a schema on the text corpus under analysis. The basic intuition behind unsupervised natural language processing techniques is that objects that appear in similar contexts in the data should be assigned similar representations, such that they can be grouped into clusters.

Unsupervised models differ according to several characteristics, from the type of information that is made available to the learner, to how similarity is defined between the different objects that are modeled, to the expected form of the output cluster that is learned. For example, the Latent Dirichlet Allocation (LDA) topic model (Blei et al., 2003) is a probabilistic model which is given access to multiple documents for training. The crucial assumptions behind the LDA model are that each document can be described as a mixture of multiple topics, and each word in a document is generated by one of the topics in that mixture. As a result of training an LDA model, multiple topics are learned, which correspond to clusters of words that tend to co-occur in the same documents.

More recently, there have been a number of unsupervised models that have been used to discover the structure of a sequence of entities and events that appear according to some narrative in the natural language processing literature (Chambers and Jurafsky, 2008; Cheung and Penn, 2013). This is accomplished by explicitly modelling the sequential dependencies of events as they appear in a document. I will provide an overview of the assumptions of the event structure being learned by such models. For example, some methods produce discrete sequences of prototypical event and participant roles. In the work of Chambers and Jurafsky, (2008), narrative chains are learned corresponding to prototypical roles in a narrative. A chain such as _ accused X; X claimed _; X argued _; _ dismissed X might correspond to a defendant in a trial. Other work frame the problem as a task for probabilistic learning. Cheung and Penn (2013) define a probabilistic sequence model, in which the structure of an event and its participants are explicitly represented in the model as latent random variables. The nature of a learned cluster, then, would be how it influences the conditional probabilities of generating other cluster labels, as well as the word emission distributions from that latent topic (as in an LDA model).

I will discuss how such models can be used to discover templates of prototypical events, including how events and event participants are typically expressed in language. Such approaches can easily be applied to multiple domains, including texts in the legal or medical genres, because they make minimal assumptions about the structure of events, and do not require training data. I also discuss other applications of these models to information ordering, and automatic summarization, which may be of interest to researchers in conceptual analysis for the digital humanities.

A computer-assisted analysis of SYMPTOM in psychiatry

Marie-Noëlle Bayle

The Diagnostic and Statistical Manual of Mental Disorders (DSM-5) is a general classification and diagnostic tool used in the rich and diverse universe of mental health. Being widely distributed and available online, it allows everyone to have a direct access on how to make a psychiatric diagnosis. To facilitate its reading, laypeople and professionals alike may consult definitions for important notions in the glossary section. However, these few lines will often fail to capture the complexity of a term. For instance, at the core of the clinical assessment of a disorder lie its signs and symptoms. Therefore, a proper understanding of what a symptom means, and how this concept relates to the disorder, is essential to the diagnostic approach.

In the DSM-5 glossary, symptom is defined as "A subjective manifestation of a pathological condition." In the practice, it is often treated as a necessary and/or sufficient condition for to seek diagnosis, or as a constraint on possible diagnoses. As such, non-doctors and patients often think of a symptom as a singular event, and conceive of it purely in terms of content and a means to a diagnosis.

However, as experience of mental disorders is often messier, we may wonder if such a notion of SYMPTOM overlooks important features of the way this notion is actually reflected in the DSM-5. Our hypothesis is that both the glossary definition for this concept and the common understanding of this notion fail to account for such essential aspects. To provide evidence for this claim, we performed a computer-assisted conceptual analysis of text (CACAT) for the concept SYMPTOM in the DSM-5. We find evidence that SYMPTOM is strongly associated to a dimension of temporality, and that it is expressed in relation not only with the disorder, but also remission. As such, it is proposed an improved definition would not only better reflect the content of the DSM-5, but could also contribute in a better understanding of assessment and practice of diagnostic.

Method

The dataset consists in a small corpus composed with the most relevant chapters of DSM-5. Computational Text mining method and manual qualitative approach were used in a processing chain for the conceptual analysis of SYMPTOM. Firstly, extraction of the textual data from noisy sources and cleaning of the text were performed. Secondly, all sentences with the term "symptom" in it, plus one sentence before and after, were extracted, yielding a set of textual segments, on which stemming and lemmatisation were performed. Thirdly, the pretreated data was used to create a document-term matrix with the TF-IDF weighting scheme. Fourthly, from the matrix, textual segment clusters were produced with the k-means algorithm. Fifthly, the most salient words in each cluster and in the whole subcorpus were first represented using word clouds. Finally, relations of similarity between the most relevant words in each cluster and in the subcorpus were represented in a 3d space. All steps were performed using common R modules (tm, RWeka, qdap, cluster, knn, ggplot2, rgl). Each cluster was interpreted as a specific field in which a hypothetical conceptual property of SYMPTOM is expressed. Categorization was done by annotating manually the most typical textual segments in every cluster according to cosine distance to the centroid. Annotations consisted in the main conceptual property of SYMPTOM expressed in a segment. Syntheses of these annotations were done for each cluster.

Experimentation

From the subcorpus, 2036 sentences containing the term "symptom" were extracted which contained 5761 different word types. The words most associated with symptom in this subset of the corpus are disord (disorder), criteria, presen (presence), sever (severity), medic (medical, medication). Using k-means, 30 clusters were extracted but 17 are deemed noisy, as they contain 10 textual segments or less. Most of the remaining clusters are located in the section II of the DSM (diagnostic criteria and codes), several having most of their segments in a specific disorder chapter. The converse, however, does not hold.

Discussion

Analysing those clusters reveals that SYMPTOM has a transdiagnostic property, and is not only defined by its specific content. For example, let us examine cluster #8, which contains 98 segments, 90% of which fall in the three chapters about psychotic and mood disorders. Symptom in this cluster is linked with the words depress, hypomania, mania, but also with episode, period, full, meet. Furthermore, annotation of joined documents shows that temporality is a conceptual property of SYMPTOM. It modifies the pathological dimension of its content. SYMPTOM is not in direct causal relation with DISORDER; it is a dynamic sign whose presence needs to be situated in an episode, regardless of whether its content is depressive or manic. Therefore, the mere presence of a symptom is not sufficient for a diagnosis. Conversely, SYMPTOM is also linked with the concept of (partial) remission. SYMPTOM and DISORDER have a complex relationship on a continuum between negative (remission) and positive (disease) poles.

In conclusion, a mixed method, combining computational and manual processing and using quantitative and qualitative approaches, was applied in our conceptual analysis of the concept SYMPTOM. SYMPTOM appears to be a more complex and dynamic concept than patients and other non-doctors usually understand it to be. As a result, a better understanding of this complexity would likely profit assessment, diagnosis and treatment of mental disorders

Introductory / Framing Remarks

Dr. David J. Kim

Dr. Kim Gallon’s essay, “Making a Case for the Black Digital Humanities,” in the most recent Debates series volume argues for the continued development of a “relationship between the digital humanities and Africana/African American/Black studies … so as to highlight how technology, employed in this underexamined context, can further expose humanity as a racialized social construction” (Gallon 2016: 42). With the recent proliferation of projects including Black Gotham, Slave Revolt in Jamaica, 1760-1761, Freedom on the Move, and T-

RACES an emerging focus on the role that geospatial technologies can have in engaging with the history of race across the African Diaspora has become an important area of digital scholarship. This hybrid 90-minute panel is a timely follow-up to a summer 2016 NEH ODH Institute for Advanced Topics in the Digital Humanities, “Space and Place in Africana/Black Studies: An Institute on Spatial Humanities Theories, Methods and Practice for Africana Studies”. The panel includes Institute faculty in a broad discussion regarding rigorous, community-based, and applied methodologies that now constitute a focus on race in the spatial humanities. Panelists will limit their presentation to no more than 10 minutes followed by a 30 minute Q&A working session to discuss the broad parameters of the sub-field and future scholarly approaches.

Spatial humanities has transformed the work of researchers, enabling profound considerations of space in relationship to human behavior and culture across time and place. Art history, literature, history, philosophy and religion – all notable fields from across the humanities – have benefited from scientific and quantitatively oriented technologies and tools to better understand the intersections between space and the human condition. It is particularly timely now to question space in relation to African-descended people’s ability to traverse and negotiate spaces in western societies. The history of the Black body and American public and private space is particularly problematical as the presence of the Black body there has been largely unwanted during long stretches of American history. Indeed, both geographical and social spatial differentiation in the United States and the larger western world has largely been predicated on racial difference, exclusion and segregation. Leading proponents of this emerging sub-field, Gallon and Nieves, are slated to co-edit a new digital book series with the University of Georgia Press. Black spatial humanities is a sub-field of the spatial humanities that – in light of the fluidity of space in relation to people of African descent in the United States, Africa and the African Diaspora – studies the children of the Diaspora across specific places and times within an epistemological framework that is predicated on an ethic of anti-racism and liberation.

The panel will highlight some of the most innovative scholarship in both analog and digital formats that rely, in part, on new technology and forms of digital scholarly publication.

The panel will address the following questions:

- How do the spatial humanities and Africana/Black Studies work together to posit and practice a different way of knowing and imagining the world?
- How do racial identities impose a certain framework on our understanding of space?
- How can the spatial humanities help us experience the lived realities of Black/Brown bodies?
- How do maps/mapping technologies reflect and/or counter the realities (the dynamism) of Black life?
- How can spatial technologies provide us with a way of understanding the forms of inhumanity attributed to or placed upon Black/Brown people?

Modeling the Nineteenth-Century Colored Conventions Movement

Dr. David J. Kim

Throughout the nineteenth century, free and fugitive blacks across the US organized more than 150 state and national Colored Conventions. Less prominent than the contemporaneous abolitionist movement in US History writ large, the Colored Conventions movement represents a complex network of black political and religious leaders, intellectuals and entrepreneurs dedicated to the cause of racial justice in education, labor, citizenship and international human rights. As an introductory case study for the panel, this presentation will discuss the Colored Conventions Project (P. Gabrielle Foreman, faculty director) and its various digital and collaborative layers of archives building. Reflecting on its initial stages, as well as looking forward to the next phase of development, it will discuss the challenges of "modeling," as a digital humanities' methodological framing, both the interpretative and the community-building possibilities of this archive: from the discovery of documents to the design of the forthcoming database.

Virtual Harlem 4.0: Experiencing the Humanities through Virtual and Augmented Realities

Dr. Bryan Carter

As technology continues to evolve at a blistering pace, digital humanists strive to incorporate ways in which these new tools for research, data visualization, haptics and mobile technologies fit into our own work. Of the many exciting tech developments, augmented reality and virtual reality are poised to make a significant impact on the way we teach, research and experience the humanities. This talk will focus on new developments within the Virtual Harlem Project to include motion and facial capture, data visualization and four-dimensional (4D) learning experiences.

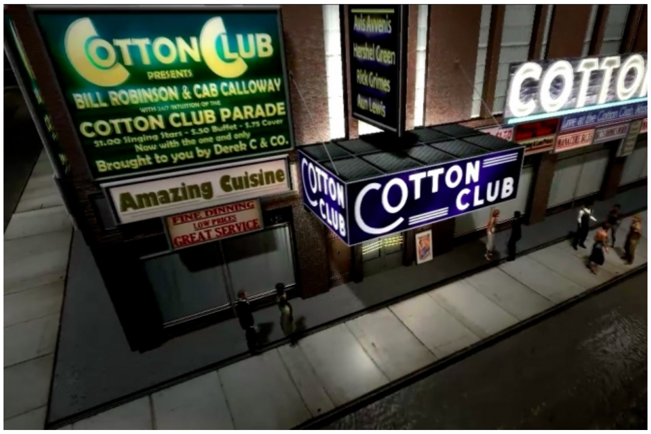

Figure 2. 3D Model, Cotton Club, Virtual Harlem 4.0

The Spatial and Digital Dimensions of the History of the Black Press

Dr. Kim Gallon

In geopolitical terms, Africana Studies scholars have studied everyday mobilities, which include the flow of people, objects and ideas backward and forward across the Atlantic Ocean. Black people's ability to move across time and space is a cornerstone for understanding their social condition. Thus, numerous scholars have documented and theorized the integral connections between black mobility and citizenship, freedom and resistance. This paper moves beyond geospatial dimensions to critically assess and examine literal spaces occupied by ideas and identities in the black press. At the same time, the use of digitized newspapers shows how black news as space can be mapped onto broader concepts concerning black people's struggle to make their humanity manifest, as well as to think critically about the various digital topographies of historical black newspapers.

Enslaved Women's Narratives in Eastern Virginia: Intersectional Approaches in GIS

Dr. Scott Nesbit

Much work in the spatial humanities depends upon the abstraction and reduction of historical processes, events, and, most problematically, actors, into data points, perhaps visualized as simple dots on a map. Scholars including Johanna Drucker and Miriam Posner have argued for more nuanced, humanities-based approaches to data visualization. Yet, if we reject inherited data visualization tools and statistics-based approaches, scholars may find at least some helpful analytical possibilities foreclosed. This talk will explore the tension at the heart of humanities data visualization in a black studies context by examining one particular question within the history of slavery and emancipation: who was escaping into United States lines during the American Civil War? The paper will argue for GIS-based approaches that are sensitive to the intersectional identities and the actions of formerly enslaved women in eastern Virginia by examining runaway slave advertisements.

3D Forensics & Historical Reconstructions: Documenting Human Rights Violations During the 1976 Soweto Uprisings

Dr. Angel David Nieves

Over the past decade, scholars and community leaders have experimented with the use of new digital technologies to tell the history of the anti-apartheid movement in South Africa. Technologies now at our disposal allow us to layer victim testimony in hypertexts using multiple tools for mapping, text mining, and 3D visualizations. Digital humanities (DH) may also help analyze documentation so as to reconstruct and recover an alternative historical narrative in the face of conventional wisdom or officializing histories for the foreign tourist market. The potential layering of the many narratives also helps lay bare the messiness of archive making, the methodologies of digital ethnography, and, in particular, the endangered nature of those archives across South Africa related to the Soweto Uprisings of June 1976. As a 3D and virtual reality enabled platform (built atop the Unity engine), the Social Justice History Platform is able to represent both 2D geospatial information (such as maps, photographs, and records) and 3D representations of landscapes, locations, and 3D models of historical buildings and objects. The project combines traditional ethnographic and oral history fieldwork with 3D technologies in the pursuit of documenting past human rights violations by the former apartheid regime.

The Mandela House
(The Mandela Family Museum)
8115 Vilakazi Street, Orlando West, Soweto

The Nelson Mandela National Museum, commonly referred to as Mandela House, is the house on Vilakazi Street, Orlando West, Soweto, South Africa, where Nelson Mandela lived from 1946 to 1962. It is located at number 8115, at the corner of Vilakazi and Ngakane streets, a short distance up the road from Tutu House, the home of Archbishop Emeritus Desmond Tutu.

Mandela donated the house to the Soweto Heritage Trust (of which he was the founder) on 1 September 1997, to be run as a museum.

It was declared a National Heritage Site in 1999.

The house is a single-story red-brick matchbox built in 1945. It has bullet holes in the walls and the facade has scorch marks from attacks with Molotov cocktails. The inside hosts some original furnishings and memorabilia including photographs, citations given to Nelson Mandela, and the world championship belt given to Mandela by Sugar Ray Leonard.

As of 2009, the property includes a visitors' centre and a small museum.

POPULARITY

In 1999, Soweto was the 16th most popular place for tourists to South Africa to visit, and that was partly ascribed to the opening of Mandela House in December 1997.

HISTORY

Mandela returned to the house after his release from prison in 1990, despite suggestions from government officials that he find a safer home. At a rally welcoming him home to Soweto his opening words were, "I have come home at last." However, after 11 days back at the house he moved out again.

He later wrote in his autobiography:

"That night I returned with Winnie to No. 8115 in Orlando West. It was only then that I knew in my heart I had left prison. For me No. 8115 was the centre point of my world, the place marked with an X in my mental geography."

Introduction

In her DH 2014 keynote address, Bethany Nowviskie encouraged digital humanists to "attend to the environmental and human costs of DH" (2015). These costs are sometimes accrued through acts of inaccessibility, such as through building websites that are not practical for screen readers or mobile devices. But they may also be accrued through acts of accessibility like exposing communities to unwanted surveillance through digital publications. (See, for example, the recent controversy around the digitization and open access publication of the lesbian erotic magazine *On Our Backs* raised by Tara Robertson in "Digitization: Just Because You Can, Doesn't Mean You Should", as well as Reveal Digital's response. Projects like Mukurtu are seeking to temper the open access movement by providing a platform that keeps the power of distribution and access within the hands of community members). These costs are accrued whether the intentions are deliberate or not.

In the environmental humanities, like in the digital humanities, "access" is not always a desirable goal. The actions of thousands of First Nations and Native American people, who continue to protest corporate and state access to tribal lands for the purpose of building pipelines, attest that access is both a human and environmental issue. In late October 2016, a viral Facebook campaign launched in the U.S. in response to unsubstantiated reports that the FBI was targeting Standing Rock, North Dakota protesters' locations via Facebook. Regardless of the veracity of the reports, the mass responses on social media—where individuals "checked in" *en masse* to Standing Rock—attest to a perceived privacy violation where personal data is accessed to enact environmental injustices. Access, especially human access, may well put endangered ecosystems at risk, expediting the "climate of extinction" in which, Nowviskie asserts, digital humanists work.

The papers in this session confront this "climate of extinction" both directly and obliquely.

Drawn from a diverse range of disciplinary fields and locales—including literature, media studies & archaeology, information science, and environmental science—this session interweaves examinations of *the lived ecologies of the digital* with analyses of *digital representations of lived ecologies*. Collectively, they address both the material and immaterial repercussions of digital humanities within the Anthropocene.

In the contact between humans, non-humans, and the more-than-human, this session asks us to consider the ways in which digital humanists and digital humanities projects are complicit in environmental degradation. How are digital tools leveraged to enact environmental injustices and destruction? How are they used to redress environmental injustice? How might we, in the words of The Dark Mountain Project manifesto “face this reality honestly and learn how to live with it” (“The Manifesto,” n.p)?

(Un)natural Disasters: The United States’ Racialized Response to Disaster Relief

Christina Boyles

Hurricane Matthew wreaked incalculable damage in the United States and Caribbean. According to the Weather Channel, "The eyewall may deliver the strongest, most destructive winds anyone in parts of the northeast and east-central Florida coast has seen in their lifetime. The last, and only, Category 4 hurricane to make landfall anywhere in northeast Florida or the Georgia coast was an 1898 hurricane south of St. Simons Island, Georgia" ("Hurricane Matthew a Potentially Catastrophic Category 4 or 5 Strike Ahead on Florida's East Coast; Strongest in Decades").

In fact, the severe impacts from this hurricane have led to some locations being uninhabitable for weeks or months. Governor Rick Scott encouraged residents of Florida's southeastern shore to evacuate. Other residents, like those farther north in Jacksonville or farther West near Orlando, were put on high alert. Over 1.5 million residents of these areas fled their homes ("Hurricane Matthew Strengthens as Florida Governor Urges Evacuations").

Not all residents of Florida had the means to escape the onslaught of Matthew. Many residents, particularly those living in rural and inland communities, did not have access to the resources needed to flee the coming storm. In fact, if history has anything to tell us, those without resources will suffer the most. In 1928, Florida was hit by a category 4 hurricane now referred to as the Lake Okeechobee hurricane. Although the loss of life was catastrophic—the Galveston hurricane of 1900 is the only natural disaster to have caused more American deaths—the legacy of the storm has largely been lost to history. Nicole Sterghos Brochu asserts that this is "because the vast majority of those who died were black migrant workers, segregated in life and abandoned in death" ("Florida's Forgotten Storm").

The fallout of the storm, however, has left a lasting cultural legacy in central Florida. Notably, anger has simmered for decades in West Palm Beach's African-American community over disparate memorials for black and white storm victims. Sixty-nine white victims in a segregated mass grave received personalized burial markers. In a nearby pauper's cemetery, a mass grave of 674 black victims was forgotten and left unmarked, later sharing space with a dump, a sewage plant, and a street extension ("Storm's Path Remains Scarred after 75 Years").

Government documents reveal that the racialized response to the 1928 storm was intentional. Seeking to protect Florida's burgeoning tourist industry, federal officials minimized the damages caused by the storm, even going so far as to dramatically underestimate the death toll. Since many individuals who lost their lives were transient—meaning their names and residences did not appear in census data—the government could easily downplay and even negate their existence.

To bring the stories of the storm's underrepresented victims back into our cultural memory, I created a Neatline exhibit demonstrating the loss of life the 1928 hurricane caused in both the United States and the Caribbean. To do so, I am also conducting interviews with family members of survivors and embedding their stories into the exhibit.

As Florida and the Caribbean start to recover from Hurricane Matthew, it is important to note that those living in economically disadvantaged communities will suffer the greatest from the storm’s damage. Heavily populated by black residents, these towns risk facing the same mistreatment of these residents both during the storm and in the recovery process, even recent storms—Katrina and Sandy are two prominent examples—reveal that discriminatory practices are common to disaster practices and clean-up processes.

In order to prevent a similar injustice it is crucial to point out the United States’ racialized responses to natural disasters and to focus aid efforts on the locations most impacted by the storm, many of which will be communities of color. By failing to do so, we risk contributing to a troublesome legacy of disaster relief discrimination.

No, Drones: Institutional Critique of UAS Data Accessibility and implications for Environmental Humanities

Nicholas Weber

Lindsay Barbieri

In name, pastiche isn’t a method familiar to most earth scientists. But in practice, monitoring and observing environmental phenomena is a recombinatory process not that different from pastiche of the art world; it requires collecting data via a network of remote sensing instruments, normalizing this information so that it can meaningfully interoperate, and combining different stores of data in order to reliably produce knowledge about the natural world. The process of knowledge production in the earth sciences is both techno-scientific (Haraway, 1997), in the sense that sources of data are historically and locally situated, but also highly contingent on evidential cultures (Collins, 1998;

Baker, 2011) in that collecting, finding and using data is mediated by the background practices of an academic department, scientific discipline, or research program.

Compare our generic description of knowledge production in environmental monitoring to Louise Lawler's recent series titled 'No Drones' – a critique of contemporary art institutions. Lawler created the series through a pastiche process of photographing private art collections, commissioning drawings of her photographs, and then digitizing the illustrations as vector-based images that are magnified and printed on adhesive vinyl (see Image 1 below). For an unassuming viewer, the result is a powerful reflexive image that is both full of layers of symbols and yet stripped down to a single black-and-white outline of complex ideas. For an audience that can unpack the provenance of Lawler's images this work also creates a self-reflexive form of institutional critique of how highly priced and commoditized artworks serve as cultural markers of wealth, privilege, and accessibility (Nixon, 2014).

This paper attempts to use the same form of institutional critique as Lawler (Fraser, 2005) in discussing the emergence of Unmanned Aerial Systems (UAS) in environmental monitoring. Our goal is to demonstrate that with reflexivity the process of producing knowledge about environmental phenomena with UAS data can shed considerable light on markers of wealth, privilege and accessibility at play in contemporary informatics-driven science. Further, we argue that by creating 'legible' provenance information, UAS data can have a dramatic impact on the burgeoning practices of environmental humanities (Castree, 2014).

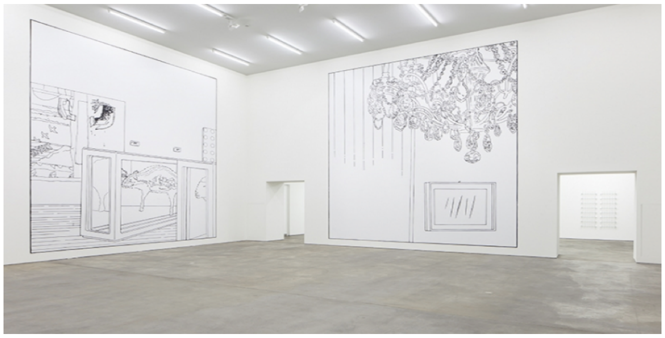

Figure 1: Louise Lawler's installation 'No Drones' at Sprüth Magers, Berlin 2015. Pictured left is 'Dots and Traces' - A drawing by Jon Buller that has been digitized and printed on a vinyl adhesive. Buller's sketch is a direct copy of photo taken by Lawler, which is itself a sculpture by Damien Hirst. (Image via Sprüth Magers)

The use of unmanned aerial systems (UAS) as tools for collecting innovative remote sensing data and geospatial imaging is increasing. Recent technological advances present communities with an opportunity to use UAS to push boundaries in data collection. The recent drop in costs combined with the advancement in lightweight technology mean UAS could become a ubiquitous means of collecting scientific data (Dunbabin and Marques, 2012). UAS are predominantly used for imagery, however, given their advantages over traditional data capture methods (higher temporal and spatial resolution, new area access, etc.) novel sensors are being explored and UAS use has opened doors for both researchers and communities interested in monitoring environment, landscapes, community vulnerability and disaster response.

We present on three important topics in UAS-based collection of environmental data (1) the results of a survey of UAS use in the earth sciences (flight platforms, data and metadata standards, and data sharing practices) and how this may shape the ability of communities to access these technologies (2) a discussion of the experience of unwanted surveillance and how drones as tools could shift the equity of surveillance (self surveillance / community surveillance) and power dynamics. (3) a discussion of how drone data collection, with unprecedented ability to capture data on environment and landscape, may shift responses of organic beings to their physiographic surroundings – a topic of growing importance for the field of environmental humanities.

The English Lake District and 'World Ecology'

Margaret Linley

In his *Guide to the Lakes* (1835), William Wordsworth famously condemns changes occurring in the Lake District since the late eighteenth century, changes accelerating ironically because visitors were flocking there from all parts of England to see the landscapes Wordsworth celebrated in his nature poetry. Wordsworth is induced to speak out "at length" by a "wish to preserve the native beauty" of the district against the transformations that seem so rapidly to be taking place. The new mobility and accessibility enabled by improved transportation and communication, however, are only part of the problem. The "invention and universal application of machinery" are, for Wordsworth, equally to blame. Rather than simply argue for isolation, Wordsworth's solution to this conundrum of access and preservation is to use the mass print genre of the travel guide as an educational platform for cultivating environmental consciousness toward a reconstitution of the Lakeland as public space: "a sort of national property, in which every man has a right and interest who has an eye to perceive and a heart to enjoy" (*Guide*).

Early in the *Guide* Wordsworth describes the process by which "nature is indebted to the hand of man," its state and appearance the outcome of historical and social processes. In so doing, he complicates a strain of environmental writing, interestingly often attributed to the Romantic legacy, which differentiates human activity from "the natural," a habit of thought that, according to ecocritics such as Jason W. Moore (*Capitalism in the Web of Life*), ultimately mystifies the role of capitalism in resource exploitation and climate change. Yet perhaps even more provocative is the way Wordsworth analyses the history of travel in the Lake District as essentially a form of colonization and insists, additionally, that the operations of such modernized forces of power on nature demand that readers think ecologically.

This paper will explore how the problem of access Wordsworth identified dovetails with concerns raised by scholars about the environmental and human costs of digital humanities (such as Nowviskie, Parikka, and Haraway, among many others) through the specific example of *Lake District Online*, a digital research project based on Simon Fraser University's collection of 260 illustrated rare books about the English Lake District, including many maps and historical specimens of ornate book bindings, illustrations, and photography, spanning 300 years (1709-2000) with a concentration in the nineteenth century. As Elizabeth DeLoughrey and George B. Handley argue, historicization has been a primary tool of postcolonial studies and it is central to our understanding of land and, by extension, the earth. In order to continue to engage a historical model of ecology and an epistemology of space in time, we must carry these concepts, not least of all the spatial imaginary made possible by the experience of place, into the dialogue around access to emerging digital environments.

Guided by this premise, *Lake District Online* has produced several freely accessible research, educational, and public engagement resources: 1) an extensible bibliographic research database for linking with other open databases (such as Wikipedia), comprising a metadata framework for searching and indexing bibliographical, biographical, and critical information about the books as well as their contents; 2) an experimental prototype of a teaching and learning platform, *Reading Up Close and At a Distance*, designed to enable students to interpret literature interactively on different scales; 3) a co-curated public exhibition with the Wordsworth Trust, *Wordsworth Country: From the English Lake District to the Pacific Northwest*, launched simultaneously at the Wordsworth Museum (UK), SFU Library and Special Collections (BC), and online; and 4) a corpus of high-resolution digital images and text files based on the SFU Lake District rare book collection. To approach these resources through the paradigm of colonial violence that Wordsworth identifies at work in the regional landscapes of Cumbria is also to engage empire building and environmental histories as highly mobile, flexible, and mutually constitutive. Moreover, as Wordsworth implies, access - and the related concept of openness - is a question of spatiality and especially of boundaries, exclusions, and limitations entailed in the politics and ethics of place making. Focusing especially on the significance of the present location of the Lake District collection in Vancouver, British Columbia, this paper will reflect on colonial legacies of organizing, producing, and accessing nature in the context of the digital humanities.

Decaying Plastic Play: *Flappy Bird*'s Hacked Afterlife as Media Archaeological Praxis

Jeffrey Moro

On March 28th, 2016, prolific YouTube streamer SethBling posted a video demonstrating how, using only timed button presses and graphical glitches present in the console original, he injected three hundred and thirty-one new bytes into the seminal 1990 Super Nintendo Entertainment System (SNES) platforming game Super Mario World—bytes corresponding to the source code of the 2013 viral iPhone game phenomenon Flappy Bird. The hack allows users to play a fully functional port of Flappy Bird within Super Mario World, grafting the former's computational logic into the latter's graphics. The choice of games here is striking; while Super Mario World has been re-released across a variety of hardware platforms—to say nothing of Mario's cultural ubiquity—Flappy Bird remains a touchstone for its inaccessibility, both in its frustratingly difficult design and the fact that in February 2014, its creator pulled it from all platforms, citing concerns that its addictiveness ruined people's lives (Nguyen). SethBling's hack then produces a chimeric object; a hybrid of plastic, logic, and time; the ghost of one game haunting the shell of another. This haunting constitutes, as this short paper argues, a regenerative practice: a "circuit bending," to draw on a theoretical and practical challenge from Garnet Hertz and Jussi Parikka, that engages the "archive" of dead (whether by accident or design) computational media not only within artistic traditions of remix, tinkering, and collage, but also with a media archaeological eye towards circulations of technological waste, supply chains, and resource extractions ("Zombie Media").

In characterizing this haunting as "regenerative," I engage interdisciplinary work in the environmental humanities and media archaeology alongside tactics from games and software studies. In a post-400ppm world, questions of digital media's emergence from and contribution to the feedback loops of climate crisis within industrial capitalism loom large. In the digital humanities, Bethany Nowviskie's oft-cited keynote at DH2014 in Lausanne provides a cri de coeur, alongside emerging conversations from the GO::DH working group on minimal computing from the same conference, for thinking through the ecological circulations and impacts of DH technologies and practices—what Nowviskie, drawing from Steven Jackson, calls the challenge of "broken world thinking" (5). Media studies as a field has also begun to take up broader questions of climate, geology, infrastructure, and the Anthropocene in theoretical and material studies of digital technologies, whether under the rubric of the "nonhuman turn" (ex. Grusin, Richard, ed. The Nonhuman Turn, U of Minnesota P, 2015); geological and elemental media histories (ex. Parikka, Jussi. A Geology of Media. U of Minnesota P, 2015; Peters, John Durham. The Marvelous Clouds: Toward a Philosophy of Elemental Media. U of Chicago P, 2015); computational infrastructure (ex. Bratton, Benjamin. The Stack: On Software and Sovereignty. MIT P, 2015; Starosielski, Nicole. The Undersea Network. Duke UP, 2015; Blum, Andrew. Tubes: A Journey to the Center of the Internet. Ecco, 2013); or sustainability and waste (ex. Gabrys, Jennifer. Digital Rubbish: A Natural History of Electronics. U of Michigan P, 2011; Acland, Charles, ed. Residual Media. U of Minnesota P, 2007; Scanlan, John. On Garbage. Reaktion Books, 2005). These diverse approaches, only a small fraction of such work, share a common reading of computational technologies both relying on and contributing to a material reorientation of human/Earth relations, whether through open-pit mining, ozone depletion, or undersea cable networking—to say nothing of new social relations made possible by the connective potentiality of such technologies.

It is no coincidence that SethBling's hack emerges at the same time as academic and environmentalist communities' explorations of technological obsolescence, material production, and sustainability/waste grow more prominent. Nor is he working in isolation: his hack is only one within of a subculture of videos exploring different ways to hack, deform, and manipulate "classic" (almost always a euphemism for "obsolete") video games. Part of these players' engagement with obsolete video games and platforms is practical: the relative (to contemporary platforms) simplicity of the hardware and coding allows for more granular engagement with the technologies themselves. But the choice of Flappy Bird and Super Mario World reveals multiple valences of computational obsolescence and decay: a game forcibly disappeared emerges within one that, through the cooperative/coercive machinations of nostalgia and capitalism, endures. Moreover, the hack itself is a kind of deliberate decay, one that deforms the digital object until it becomes pliable, manipulable, and inscribable. Much like the acrylonitrile butadiene styrene (ABS) that comprises its cartridge shell, the game becomes plastic: transformable, recyclable, and pliable under the right (industrial) conditions.

At its root, this hack plays (in multiple senses of the word) with the roots, tendrils, and growths of computational memory. It reveals "memory" as a function of physical hardware, the encoded rhetoric of software, and the transmission of shared culture. Wendy Hui Kyong Chun, in her 2008 book Programmed Visions, offers the idea of software's "enduring ephemerality," computational media's capacity to "remember" through material regeneration—continual acts of writing and rewriting across electrical charge and silicon (148). Through this frame, SethBling's hack is rewriting, and its ingenious incarnating and recycling of Flappy Bird's three hundred and thirty-one bytes embodies Chun's claim that "what is not constantly upgraded or 'migrated' or both becomes unreadable. . . . The experiences of using—the exact paths of execution—are ephemeral. Information is 'undead': neither alive or dead, neither quite present or absent." (148). Hertz and Parikka deploy "zombie" as a metaphor for reinvigorated dead media to similar ends, observing that the materials constituting software—the plastic, the rare earth metals—are also subject to regimes of ephemerality (150–53). ABS, in its petroleum-based non-biodegradability, may be effectively immortal, but the systems through which humans articulate its use are subject to entropic decay. Only the ephemerality endures.

This paper closes by offering SethBling's hack and the broader gaming subcultures of glitch play to which it belongs as artistic responses to computational obsolescence and decay. Chun's "enduring ephemerality" becomes artistic praxis much as Hertz and Parikka offer circuit bending as a media archaeological arts method. It extends the material concerns of media studies' Anthropocenic turn to code and its cultures, and offers these deforming/reforming modes of play as potential sites of resistance for an ecologically-engaged digital humanities practice.

Resumen

En las universidades iberoamericanas las Humanidades Digitales están construyendo un campo emergente con diversas iniciativas a nivel institucional. Las instituciones de educación superior poseen características diversas que las distinguen por sus recursos humanos y financieros, sus infraestructuras físicas, tecnológicas y administrativas, sus modelos educativos y sus programas de estudio. Esta heterogeneidad genera condiciones diversas para la consolidación del campo. Sin embargo, aunque los contextos varíen, nos encontramos con elementos comunes en esas estructuras institucionales que obstaculizan el desarrollo de las Humanidades Digitales y, a la vez, pliegues o espacios liminales que posibilitan su avance. Este panel tiene el propósito de a) presentar un marco de referencia general sobre las HD en Iberoamérica, b) realizar un análisis de los desafíos como campo y un balance de los factores determinantes para el avance de las HD en español, c) identificar las estrategias que han sido aplicadas para la expansión de las HD en la región y, d) proponer acciones en red y mecanismos dentro de las universidades que permitan la consolidación del campo, a través de la práctica docente, la investigación, el desarrollo de capacidades, la formación de recursos humanos y la vinculación social de las Humanidades Digitales en el marco de los principios de una cultura digital crítica y libre.

Descripción

En Iberoamérica existen instituciones de educación superior con características diversas que las distinguen por sus recursos humanos y financieros, sus infraestructuras físicas, tecnológicas y administrativas, sus modelos educativos y sus programas de estudio. Esta multiplicidad de contextos genera dinámicas y espacios diferenciados para la consolidación de las Humanidades Digitales en la región. Dentro de este contexto institucional variado, las HD en español están construyendo un campo emergente que posee características que lo distinguen de las experiencias en otras regiones y otras lenguas. Sin embargo, al abrir un línea de trabajo nos encontramos con múltiples elementos de esas estructuras institucionales que obstaculizan su avance. La formación de profesionales y el desarrollo de proyectos digitales se enfrentan a una serie de problemáticas dentro de las que se encuentran decisiones administrativas, el desconocimiento sobre el campo, las carencias en infraestructura o de mecanismos para que las universidades incluyan nuevas temáticas en el currículo a nivel de licenciatura, posgrado o como líneas de investigación.

Sostenemos que las instituciones cuentan con una serie de elementos estructurales que, a su vez, forman parte de un sistema de educación pero también de producción de conocimiento, por ello enumeramos aquí algunos de los elementos externos e internos del contexto en el que buscamos consolidar las HD en Iberoamérica con el fin de presentar un diagnóstico y una propuesta que permita a las instituciones tomar decisiones estratégicas si buscan transitar a un nuevo paradigma.

- Administración: las instituciones cuentan con un aparato administrativo que, en ocasiones, representa un obstáculo para el desarrollo de nuevas propuestas. El planteamiento de nuevos contenidos y conocimientos debe sujetarse a la estructura administrativa, lo cual puede permitir o impedir el desarrollo de las HD.
- Evaluación de la producción académica: aunque no es un problema nuevo, la presencia de medios

digitales complejiza la valorización de los productos intelectuales, sólo tangibles en productos ya validados, como los libros o los artículos, sin embargo, hoy es posible desarrollar productos en soportes y formatos diferentes para los cuales no existe aún un mecanismo de validación o el que existe no ha sido adaptado para estas nuevas formas de producir conocimiento.

- Modelo educativo, planes de estudio y propuesta pedagógica: los distintos modelos educativos, planes de estudio o propuestas pedagógicas, sea cual sea el programa o nivel académico, obedecen a la división tajante del conocimiento en disciplinas, ello impide en la mayoría de los casos, impartir asignaturas que integren nuevas visiones pedagógicas, formas de trabajo, objetos de estudio, teorías y métodos de investigación o incluso romper con la compartimentación disciplinaria y la ampliación de entornos de aprendizaje
- Comunidad y cultura digital: la formación de profesionales depende no sólo del interés de los docentes, sino también de los propios estudiantes. Ambos grupos reconocen la necesidad de adquirir nuevos conocimientos y competencias digitales pero en muchas ocasiones únicamente desde un enfoque instrumental, lo cual no implica una reflexión sobre el impacto de medios digitales y de internet en el desarrollo de sus disciplinas.
- Infraestructura tecnológica: el acceso en términos de conectividad, hardware y software.
- Transdisciplinar: resultado de la fragmentación y especialización disciplinar dentro de las estructuras universitarias, el trabajo colaborativo interdisciplinar y transdisciplinar es aceptado con cierta reticencia, dado que su desarrollo debe apegarse a las estructuras académicas y administrativas ya establecidas.
- Financiamiento: la investigación requiere de recursos económicos para la realización de proyectos pero también para la formación de los humanistas. Los aspectos mencionados se encuentran dentro de un contexto más amplio que reafirma la división estricta entre disciplinas, lo cual incide en el financiamiento para proyectos digitales desde la perspectiva de las HD. El acceso a recursos internacionales es limitado puesto que requiere de redes de colaboración y capacidades con las que no necesariamente cuentan los investigadores. Políticas públicas.

A pesar de que esta estructura institucional no siempre es favorable para el avance de las HD, se han desarrollado iniciativas en las universidades que van desde la organización de eventos de HD, la publicación académica de revistas especializadas, la creación de plataformas, la vinculación con otras iniciativas en el marco del movimiento de acceso abierto (MOOC, bases de datos, bibliotecas digitales, Wikipedia); hasta la implementación de laboratorios como parte de la estrategia para abrir o consolidar la práctica de las HD. El panel sobre Humanidades Digitales en Iberoamérica esbozará un estado de la cuestión y, a través de las diversas experiencias institucionales de los panelistas, buscará identificar los principales desafíos, prácticas exitosas y propuestas para generar mecanismos dentro de las universidades que permitan avanzar en el desarrollo del campo, la práctica docente, la investigación, el desarrollo de capacidades, la formación de recursos humanos y la vinculación social de las Humanidades en el marco de una cultura digital crítica y libre.

Introducción al panel

El panel muestra diversos intereses, aunque con un objetivo común: conocer las estrategias que han sido aplicadas para la expansión de las HD en Iberoamérica. Aunque existen algunos mapas y registro de proyectos, nuestro interés es entrar a profundidad en el análisis de algunos factores que consideramos determinantes para el avance de las HD en español. Como punto de partida, el panel presenta un marco de referencia general sobre las HD en Iberoamérica como introducción a los casos y cierra con un balance de la situación y los desafíos como campo con el propósito de identificar continuidades y fortalecernos a través de estrategias compartidas.

El panel aborda estudios de casos relevantes que reflejan la labor de las instituciones Iberoamericanas en las se han desarrollado proyectos e iniciativas para extender las HD, que han generado ya redes de colaboración y un sentido de pertenencia y reconocimiento mutuo. Este panel como resultado de esas redes de cooperación interinstitucional e internacional busca consolidar una apuesta conjunta, generar un espacio de discusión abierto y dar visibilidad al trabajo heterogéneo que se realiza en Iberoamérica. Si bien no se mapean todos los casos de HD en Iberoamérica, hay una voluntad explícita de incorporar, reconocer y rescatar las iniciativas de la región. Esperamos que a partir de la oportunidad de una discusión pública, podamos, en un futuro próximo, integrar académicos y experiencias de otras instituciones y países.

Desde Iberoamérica la comprensión de las HD es más amplia que en el mundo anglosajón, lo que muestra también un desafío en términos académicos, administrativos y de práctica de las HD. Consideramos relevante destacar nuestros contextos específicos de acción para luego identificar las estrategias más efectivas para avanzar en el campo, no únicamente a través de proyectos, sino a través de la formación de estudiantes, el desarrollo de competencias entre los investigadores y el incentivo de formación a futuro de una infraestructura colaborativa. Sostenemos que es necesario conocer el estado de la cuestión desde los aspectos más macro hasta los más micro.

La inclusión de temas sobre tecnología, educación, cultura digital y transformación institucional en el panel responde a la necesidad de presentar la pluralidad de estrategias, proyectos e iniciativas que buscan ampliar las posibilidades de institucionalización de las HD, generando condiciones básicas para avanzar en la reflexión, el planteamiento de nuevos proyectos y la consolidación del campo en la región.

Las HD en los programas de Licenciatura de Humanidades. Estado de la cuestión

Adriana Álvarez Sánchez

Miriam Peña Pimentel

La división del conocimiento en Áreas ha permitido un alto grado de especialización disciplinaria, sin embargo, la inclusión de nuevos objetos de estudio - incluidos los digitales - requiere aproximarse y, en ocasiones, transitar hacia otras áreas del conocimiento, para ello es necesario que los estudiantes en formación conozcan no sólo los principios teóricos y técnicas de otras disciplinas, sino que lleven a la práctica esa interdisciplinariedad. Ello podría conseguirse si durante la licenciatura (bachelor) cuentan con, al menos, una experiencia de trabajo colaborativo con estudiantes de otras áreas. La inter y transdisciplina son consideradas características inherentes de las HD; por ello, la réplica de esta forma de trabajo podría ser incorporada a los planes de estudio actuales. El uso de recursos y herramientas digitales facilitan la colaboración entre disciplinas; sin embargo los planes de estudio actuales no consideran esta vinculación como un requisito, por el contrario, la tendencia en el "entrenamiento" de los estudiantes, tiende hacia el individualismo y la hiper-especialización; la única posibilidad de conexión con otras áreas del conocimiento (humanístico, social o científico) es la posibilidad de cursar materias optativas en otras facultades o de otras disciplinas -siempre y cuando se demuestre cumplir con los pre-requisitos de cada materia, condición que se cumple con dificultad entre más "alejadas" estén las disciplinas-; la gestión o desarrollo de proyectos en pequeña o gran escala, no se enfocan en entablar procesos de investigación colaborativos, las estructuras jerárquicas se mantienen y la cadena de aprendizaje mantiene el status quo; perpetuando el modelo "tradicional" de trabajo. Es importante señalar que esta propuesta no ataca o desprestigia la estructura ni las formas tradicionales de la academia, por el contrario, busca ofrecer una serie de recomendaciones que en convivencia enriquezcan la experiencia universitaria en los diferentes niveles de acción: estudiantado, profesorado, investigación y administración.

En esta ponencia nos centraremos en dos disciplinas concretas: Letras Hispánicas e Historia.

La Licenciatura en Filología Hispánica tiene diferentes connotaciones dependiendo de la Universidad que imparta el programa de estudios (Lengua y Literatura Hispánicas, Letras Hispánicas, Literatura Latinoamericana, etc.); el nombre de la carrera denota la tendencia a la que se enfoca cada licenciatura, desde el formato más general (lingüística y literatura), hasta el de enfoques delimitados (literatura latinoamericana); sin embargo, para fines prácticos, los egresados de cualquier modalidad de esta licenciatura, cuentan con una instrucción similar a lo largo de 8 semestres. A pesar de las diferencias en los planes de estudio que aquí se presentarán, en su mayoría coinciden con una falta evidente de apertura hacia la inclusión de propuestas "alternativas"; en el caso de la UNAM, por ejemplo, el plan de estudios de la Licenciatura en Lengua y Literatura Hispánicas es de 1999; razón por la cual se entiende innecesario incluir una línea pedagógica hacia las Humanidades Digitales (o hacia la literatura electrónica o las "nuevas tecnologías"); sin embargo, en planes más contemporáneos (2012 en el caso de la Universidad Iberoamericana), encontramos faltas similares que, a juicio de las autoras de esta propuesta, de incorporarse a las prácticas pedagógicas podrían dar parte a una serie de programas interdisciplinares con tendencia a las Humanidades Digitales y la Pedagogía Digital; tendencias que consideramos necesarias para la innovación académica en las regiones periféricas.

La Licenciatura en Historia de la Facultad de Filosofía y Letras, de la Universidad Nacional Autónoma de México (UNAM) es un programa centrado en la historiografía como eje rector de la formación de un historiador al que se busca formar para la investigación, la docencia y la difusión. No obstante, que el programa fue creado a finales de los noventa, en su contenido únicamente se menciona en una ocasión Internet como parte de los métodos de búsqueda bibliográfica (Plan de Estudios de la Licenciatura en Historia, 1999, Vol. I, p.67).

Para realizar el diagnóstico planteado en el panel, se llevará a cabo una revisión crítica de los planes de estudio de estas Licenciaturas que se ofertan en la ciudad de México: Puesto que ambas licenciaturas tienen presencia en la mayoría de las universidades capitalinas, se decidió revisar los planes de estudios de las mismas instituciones: la Facultad de Filosofía y Letras (Escolarizado), UNAM; Universidad Autónoma Metropolitana, Iztapalapa, y Universidad Iberoamericana, esta última de carácter privado. El objetivo, además de comparar los programas, es identificar "áreas de oportunidad" para plantear una propuesta para impulsar la interdisciplinariedad y el trabajo colaborativo a través de medios digitales, lo cual implicará considerar temas como el acceso, la infraestructura, etc., es decir, el contexto institucional de cada caso. Se considerarán las experiencias institucionales que la autora de la ponencia, en colaboración con la Dra. Miriam Peña Pimentel, han tenido como profesoras del Seminario Taller Especializado Humanidades Digitales (2014-2015) e Historia, e Historia Digital (2016) dentro de la Licenciatura en Historia, UNAM; el Seminario de Humanidades Digitales (2013-2016) y la Optativa: Humanidades Digitales en los estudios literarios (2016-2 y 2017-1); además de esfuerzos semejantes llevados a cabo en otras instituciones mexicanas, sin dejar de lado el contexto mundial. Todo ello con la intención de presentar un diagnóstico conjunto que permita crear un modelo para introducir las HD a nivel licenciatura en México.

La evaluación del conocimiento en la sociedad digital. Progresos para una alternativa en Humanidades Digitales

Esteban Romero Frías

Weller (2011), autor del libro The Digital Scholar, emplea el término Digital Scholarship para referirse al conjunto de actividades académicas facilitadas por las nuevas tecnologías. Un conjunto de cambios profundos que, para este autor, son producto de la convergencia de tres elementos: lo digital, lo conectado en red y lo abierto. Las transformaciones digitales producidas en el espacio de las Humanidades, denominadas Humanidades Digitales, representan un caso de especial interés para observar el desarrollo de estas prácticas, en muchas ocasiones conflictivas. Goodfellow, en un artículo de 2013 titulado "Scholarly, digital, open: an impossible triangle?", señalaba justamente que lo abierto, lo académico y lo digital, constituyen categorías difícilmente compatibles tal y como se consideran en la actualidad. Ciertamente, en el ámbito de las prácticas digitales vinculadas al conocimiento, el conjunto de categorías que hay que tener en cuenta es muy diverso, existiendo un continuo en una pluralidad de dimensiones en las que podemos situar los distintos casos con los que nos enfrentamos. Algunas de estas categorías son, entre otras: lo académico/no académico, lo digital/analógico, lo abierto-cerrado. Junto a esto surgen en el ámbito de la sociedad digital nuevas formas de generación y difusión del conocimiento que no son reconocidas por los sistemas de evaluación tradicionales centrados en el impacto bibliométrico. Más allá aún, la apertura que generan los medios sociales hace preciso medir otros impactos de la vida académica aparte del vinculado a la investigación. Esta problemática se agrava particularmente cuando nos referimos a las Humanidades Digitales, herederas de modelos tradicionales asentados durante muchos años. Para un efectivo desarrollo y consolidación de las Humanidades Digitales es preciso identificar y evaluar los nuevos artefactos digitales académicos que en muchos casos constituyen el principal resultado de un proyecto o de la carrera de un académico.

El proyecto Knowmetrics - evaluación del conocimiento en la sociedad digital, financiado en julio de 2016 por la Fundación BBVA en la línea de Humanidades Digitales, desenvuelve precisamente su trabajo en dos líneas. En la primera, con una perspectiva micro, se centra en la identificación de investigadores en Ciencias Sociales y Humanidades Digitales, en la elaboración de una taxonomía de artefactos digitales académicos y de indicadores para evaluarlos y en la propuesta de informe integrado de los impactos de la vida académica para humanistas digitales, incluyendo diversas dimensiones, desde la investigación a la implicación social. En la segunda línea, con una visión macro, trabaja en la evaluación del impacto digital del conocimiento en la universidades a través de diversas aproximaciones: a través de un índice Knowmetrics que se apoye en el trabajo anterior, a través de altmetrics y de medios propios de Internet, como es el caso de Twitter.

La aportación en la mesa redonda que se propone permitirá dar a conocer los avances efectuados por dicho proyecto cuando se encuentre en el ecuador de su ejecución en 2017.

Repensar la producción de conocimiento, las instituciones y las humanidades digitales

Virginia Brussa

Paola Ricaurte

Enedina Ortega

En nuestro actual contexto, son frecuentes los cuestionamientos con respecto a la labor de las universidades, el sentido de la producción académica y su vinculación con los complejos problemas que aquejan a la sociedad. De acuerdo con Heleta (2016) los académicos no se encuentran perfilando los debates públicos. Menciona que anualmente se publica un millón y medio de artículos en revistas académicas, que son en su mayoría ignorados por la comunidad científica. En el caso específico de las humanidades, menciona que el 82% de los artículos no se cita ni una vez. Ello enfatiza una problemática que va más allá del acceso, también denota la necesidad de acción y agenda amplia de lo "abierto".

En una entrevista realizada a Saskia Sassen (Torres, 2016) la socióloga destaca que el mundo académico no está respondiendo a las particularidades del momento. Los académicos, menciona Sassen, se "instalan" en zonas de confort: su carrera académica, sus publicaciones, el uso de categorías dominantes, y no arriesgan, ni en la comprensión profunda y problematización de los conceptos para abordar fenómenos contemporáneos, ni en abrir nuevas fronteras de investigación. Kathleen Fitzpatrick (2011) utiliza el concepto de obsolescencia como una categoría pertinente para dar cuenta de una serie de condiciones culturales asociadas con el sistema actual de producción y difusión del conocimiento en horizonte tecnocultural: la revisión por pares, las nociones de autoría, la categoría del texto y el papel de la universidad.

Esta situación pone de relieve al menos tres problemáticas que nos interesan: por una parte, la necesidad de reconfigurar el papel (y la estructura administrativa) de las instituciones educativas para que den respuestas a los problemas sociales desde nuevas aproximaciones y espacios de "encuentro" ; por otra, transformar los sistemas de producción de conocimiento; y por último, reflexionar sobre el lugar de las humanidades (específicamente digitales) en este escenario. En este último punto, enfatizar el estado de situación de modalidades de

Labs y la creación de herramientas digitales en el seno de nuestros espacios de HD.

Esta propuesta tiene como propósito ofrecer un panorama sobre a) un modelo de transformación institucional; b) una estrategia que permite reconceptualizar la producción de conocimiento desde la academia; y c) una apuesta para promover visiones alternativas sobre el trabajo de los académicos en las humanidades (digitales).

Si buscamos el desarrollo y la consolidación de las HD como campo en Iberoamérica, es necesario fortalecer espacios que fomenten modalidades democratizadoras y colaborativas en la producción de conocimiento, frente a la institucionalidad, estructura y formas pedagógicas propuestas en el seno del ámbito académico actual. Sostenemos la caducidad y el agotamiento de las instituciones sociales (universidad, partidos políticos, dependencias gubernamentales) concebidas como sistemas cerrados y autocontenidos, desconectados de la ciudadanía. Apelamos a la conformación de extituciones: formas organizacionales abiertas a la participación ciudadana como un aspecto fundacional de su constitución y operación.

La universidad debe reconfigurarse bajo este modelo para tener cabida en las nuevas dinámicas sociales. En este sentido, planteamos que las Humanidades Digitales no deberían estar exentas de estos debates y desafíos si se encuentran inscritas en los valores de colaboración, apertura e interdisciplinariedad. Manifestamos la necesidad de una opción crítica y pública en las humanidades que se hacen desde el sur global. Por esta razón, consideramos pertinente repensar los modelos triple hélice que consolidan los lazos entre universidad, gobierno y sociedad civil.

Frente a ello, nuestra propuesta se basa en presentar un planteamiento sobre la vocación y orientación de la humanidades en nuestra región, que contempla una serie de propuestas relativas a nuevas visiones, temáticas, procesos y proyectos. En relación con el impulso de los debates sobre la universidad de hoy, es menester hacer mención a la creación de nuevos espacios, metodologías y modalidades de producción del conocimiento, a la conformación de otras redes con comunidades y organizaciones, a la incorporación de esquemas flexibles y alternativos de colaboración, a las formas de mediación y las conversaciones en distintos niveles de lo “abierto”: institucional (gobiernos, universidades, ONG), temáticos (gobiernos abiertos, datos abiertos, ciencia abierta, ciencia ciudadana), procesos y herramientas. Consideramos que desde las universidades es importante rescatar la vocación de experimentación y la generación de conocimiento en abierto para transformar la cultura académica, el entorno y las comunidades. Las humanidades tienen una oportunidad invaluable de incidencia en este proceso.

Proponemos por tanto, líneas de acción que podrán aportar a dichos debates y problemáticas que enfrenta la universidad, así como el impacto que ello conlleva para la materialización de las Humanidades Digitales críticas y públicas en el ámbito regional.

La reconfiguración social de aprender en red

Cristóbal Suárez-Guerrero

Paola Ricaurte Quijano

La educación de hoy se piensa y hace en internet. No obstante, el perfil y el papel de los agentes educativos en los entornos de aprendizaje en red es algo que cuesta definir no solo por la multiplicidad de agentes que hay, sino porque el paradigma dominante de “experiencia de aprendizaje” está sujeta a la relación unidireccional de profesor-estudiantes. Esta matriz de relación educativa entra en crisis cuando hablamos de interacción educativa en internet. Por tanto, más allá de las herramientas tecnológicas es preciso preguntarse ¿qué implica hablar de lo social cuando nos encontramos aprendiendo en internet? Para dar respuesta y entender la importancia de lo social en el aprendizaje hay que apelar a una pregunta invisible en el modelo educativo centrado en el docente: “¿con quién aprender?”

Como entorno de aprendizaje, internet es un entorno abierto –demasiado abierto para muchos- de aprendizaje donde su principal valor –junto al acceso a recursos- es la posibilidad de construir redes entre sujetos para aprender y trabajar con metas compartidas. Si hablamos de aprendizaje, la estructura de estas redes puede facilitar o potenciar los procesos de aprendizaje y la generación de conocimiento. No obstante, internet como entorno de interacción social no es uniforme. Hay que tener en cuenta que este entorno social en red, que configura internet, coexisten distintas formas de comunicación, las tradicionales, pero también formas emergentes e inéditas de comunicación y coordinación humana. Este panorama educativo en red implica, por lo menos, tres retos sociales para repensar con quien aprender: 1. Entender internet como ambiente social de aprendizaje más que como un entorno tecnológico. 2. Reconocer qué nuevo rol de aprendizaje se cumple dentro de la estructura social en red, y 3. identificar las transformaciones digitales de las organizaciones educativas en torno a la cultura educativa.

Para mostrar la reconfiguración social potencial se presentan una serie de casos que pueden dar una idea de la amplitud de perfiles y experiencias que ahora existen en la red. No obstante esta selección es parcial, y queda por desarrollar una serie patrones recurrentes en el trabajo en red y una serie de perfiles que abarcan, como se señala en el Peeragogy Handbook (Rheingold et al. 2015) roles potenciales en el proceso de aprendizaje entre pares tanto en los espacios digitales como físicos: el co-líder, co-director del equipo, editor, autor, procesador de contenido, revisor, presentador, comunicador, diseñador, curador, creativo, traductor, estratega, gerente de proyecto, coordinador, asistente, participante, mediador, moderador, facilitador, etc. A pesar de la variedad de nombres que pueda recibir “¿con quién aprender?” hay que reconocer que estamos frente a nuevos roles educativos. Todos estos roles tienen un denominador común: existen porque las condiciones de aprendizaje se han abierto más allá de la docencia y se emplea la red para crear otras formas de relación.

Por tanto, la aportación en la mesa redonda consiste en enfocar internet como un entorno educativo en red donde, además de la enseñanza, caben otros flujos de comunicación y formas de aprendizaje. Esto empuja a redefinir nuestra otredad al momento de pensar la pedagogía y el aprendizaje en distintas disciplinas y un desafío para la práctica de las Humanidades Digitales.

La urgencia de políticas de incorporación de TIC pertinentes en el área de humanidades: estudio de caso, Universidad Veracruzana

Ana Teresa Morales Rodríguez

Alberto Ramírez Martinell

La Sociedad de la Información y el Conocimiento (SIC), es un paradigma postindustrial que asume como materia prima la información, donde se asevera que la productividad está basada en la generación de conocimiento (Castells, 2001). En esto, las TIC son un elemento fundamental que provoca alteraciones, rupturas y rompe esquemas en diversos ámbitos (Brunner, 2005). Cambian los modos de producción (Gibbons, 2001), las formas de socializar son distintas y para cada disciplina hay transformaciones específicas (Becher 2001; Trowler, 2012). Lo que hace necesario que los futuros profesionales sean capaces de incorporar las TIC en sus campos de conocimiento.

Es por eso que las Instituciones de Educación Superior (IES) se han ocupado en incorporarlas en el contexto universitario y ponerlas a disposición de la comunidad universitaria. Entonces, se invierte en tecnología y proyectos de incorporación de TIC para que los egresados sepan usarlas. Pero ¿qué tan pertinentes y efectivos son estos proyectos y políticas?. En el caso de la Universidad Veracruzana (UV), los esfuerzos por incorporar las TIC, se hacen visibles en los planes de desarrollo que los rectores han planteado desde finales de los años 90 (PETIC, 2012), a partir de los cuales se han dictado las estrategias y líneas de acción para la incorporación de las TIC, entre las que destacan: la dotación de infraestructura (equipamiento, conectividad y servicios tecnológicos) para cada una de sus entidades académicas (PETIC, 2012) (las cuales se encuentran distribuidas en cinco regiones geográficas distintas); la implementación de programas de formación en TIC para el profesorado; la puesta en marcha de proyectos como AULA, en el que se capacita a profesores universitarios para el uso de TIC tanto para el diseño de sus clases como para su ejecución; el establecimiento de un marco común de computación para todas las licenciaturas de la universidad; la ampliación de la oferta de servicios de TIC institucionales como iTunes UV, la biblioteca virtual, el sistema de información distribuida Eminus creado al interior de la universidad, entre otros. Dado este contexto, es importante reflexionar que la incorporación de las TIC, implica no solo la dotación de infraestructura, sino que es necesario contar con habilidades digitales para usarlos recursos ya que se desconoce si se está garantizando que los estudiantes de las distintas disciplinas sean capaces de usar las TIC en sus actividades profesionales. Al analizar las políticas de incorporación de las TIC hemos observado que éstas han sido implementadas de manera homogénea (Morales, Ramírez y Excelente, 2016), aún cuando el sistema superior está fragmentado de acuerdo a las diversas disciplinas que convergen al interior.

Implementar políticas de incorporación de TIC de manera homogénea, no permite considerar las necesidades propias de cada disciplina, lo que evita una incorporación pertinente y por lo tanto ineficaz. Es por eso que en el proyecto de Brecha Digital, se ha diseñado una metodología para el análisis de los saberes digitales que requieren los egresados de distintas disciplinas (Casillas y Ramírez 2015). En esta se realizan discusiones colegiadas con las comunidades de académicos de determinada disciplina y se consensan cuáles son los saberes informáticos, informacionales, los requerimientos de comunicación, los elementos de ciudadanía digital y el software especializado, propio de cada disciplina. Esta información sirve como insumo para la actualización de programas de estudio de las carreras en cuestión, y de esta manera la incorporación se plantea que los expertos en cada disciplina (los profesores) puedan definir los saberes digitales mínimos que un egresado debe tener; esos que le permitan apropiarse de tecnologías que puedan usar en apoyo a su disciplina. Así mismo se han llevado a cabo análisis desde diferentes aristas, en los que encontramos que en el área de humanidades hay rechazo al uso de las TIC por parte de algunos profesores, la visión acerca de las posibilidades que éstas les brindan, aún son limitadas. Las pocas innovaciones que hay en el área de humanidades digitales, son escasas y provienen de profesores protecnológicos (Darín, 2015), y a pesar de que éstas resultan enriquecedoras, es necesario y urgente diseñar estrategias que permitan a la universidad encaminar a las carreras de humanidades hacia el uso de las TIC y dejar de tener solo casos de éxito aislados. Es preciso que el análisis y discusión de cuáles son los saberes digitales que deben desarrollarse en los estudiantes de manera diferida en su formación profesional, se plantee a nivel institucional, ya que urge desarrollar en los estudiantes, habilidades que les permitan adaptarse a los cambios tecnológicos, pues de no hacerlo estarían dejando ir una de las grandes oportunidades que ofrece el mundo moderno y en la pasividad se quedarán en el papel de espectadores. Es necesario poder dar a los estudiantes de humanidades (y de todas las áreas), un capital tecnológico que pueda darles ventajas competitivas, hacerlos parte de los cambios y reconfiguraciones actuales, que sean dinámicos, y a su vez congruentes con las necesidades sociales.

Studying Literary Characters and Character Networks

McGill University, Canada

The study of character has long been one of the central concerns of literary theory. For the Russian formalists, embodied above all in work of Vladimir Propp (1968), character was primarily a "type," one that served different narrative functions ("the hero is married and ascends the throne"). For poststructuralists that came in the wake of Propp, character was nothing more than a rhetorical "effect," one more example of the referential phallacy of naïve readers (Barthes 1970; Culler 2002). Subsequent studies attempted to account for this dual nature of characters, the they are both rhetorical devices and also constrained by real-world references, the requirements of being human that constrain what characters can do and say (Phelan 1989; Jannidis 2004; Frow 2014). More recent research has begun to emphasize the affective or identificatory role that characters play for readers (Lynch 1998; Brewer 2011). According to this view, characters are the media through which readers come to terms with new kinds of social experience. Drawing on the field of cognitive science, other work by Zunshine (2006) and Vermeule (2011) has argued in a less historical vein that characters are useful tools through which to model "theories of mind," means for learning about and hypothetically experiencing human cognition.

It is within this context that our three papers situate themselves in order to understand the ways in which computation impacts the study of literature. Each is fundamentally concerned with how the increased volume of information surrounding characters impacts our understanding of the idea of character – whether it is examining several thousand plays in which characters appear, several thousand interactions between characters, or the millions of words surrounding characters' appearance on the page. Characters are fundamentally social in literature and these computational methods are designed to better understand that sociability.

Mark Algee-Hewitt's paper concerns itself with the study of social networks in 3,900 plays across four-centuries. It asks how the morphology of the social networks represented on stage represent (or resist) both the politics and aesthetics of a period and, more importantly, how those social networks evolve over time? In his paper, he will move beyond the network analysis of a single play by examining the network structure of a large corpus of English dramas written and performed between 1500 and 1920. By applying a series of summary statistics drawn from the field of social network analysis to the individual plays, he is able able to trace the history of dramatic representations of the social sphere and shed new light on the evolution of both the protagonist and the periphery in modern drama.

Khoustiv Sinha, Andrew Piper, Derek Ruth's paper takes a step back to ask the even more fundamental question: what *is* an interaction? Before we move to the extraction and mapping of social networks in fiction, we first need to study how readers understand the very idea of "interaction." In this project, he examines reader annotations across a data set of over 1,000 social interactions drawn from popular contemporary fiction and non-fiction. In doing so, he addresses not only the level of agreement between readers, but also the types of interactions that produce more or less agreement among readers. What are the qualities of social relationships in literature that generate more ambiguity among readers and what does that have to tell us about the social investments of literary texts?

Finally, Andrew Piper and Hardik Vala's paper introduces a new tool that identifies 28 different features aligned with practices of characterization. These features range across a variety of different categories, from positionality (the character's agency), modality (behavior), descriptiveness, to social categories like proximity to other characters or the distribution of character counts in a text As they will show, this tool can allow us to derive novel insights about the history of character development in literary texts.

Distributed Character: Quantitative Models of the English Stage, 1500–1920

Mark Algee-Hewitt

The use of network graphs to represent social networks of characters within novels or plays has played an important role in quantitative textual analysis (see for example Agwar et al 2012, Bingenheimer et al 2011, Elson et al 2010). In this paper, I move beyond the network as a visual object, and instead, draw upon the quantitative metrics of the graph to explore the large-scale changes to the structure of English drama across four hundred years. What can the overall structure of the play can tell us both about the aesthetics of literary production of a given period, and what we can learn about the play by disaggregating the morphology from both the stagecraft and the language that, until now, have made up the two poles of dramatic criticism?

The power of networks lie in their precise, mathematic, description of a set of relationships that can be quantified, measured and aggregated in ways that are unavailable to the reader of a text. Yet, most work has been focused on the use of single networks to describe single plays. For example, in his work on character networks in *Hamlet*, Franco Moretti turns quickly from the quantitative network analysis to the qualitative approach to the plot: "I soon realized that the machine-gathering of the data, essential to large-scale quantification, was not yet a realistic possibility [...] So, from its very first section, the essay drifted from quantification to the qualitative analysis of plot" (Moretti 2011). In this paper, I introduce an automated, rule-based, parsing of the 3439 English plays in the Chadwyck Healy drama corpus in order to perform the kind of large-scale quantitative analysis that Moretti gestures towards, but is unable to realize. The algorithm uses the existing XML markup in the corpus in order to extract speeches and assign them to characters as speakers and recipients, resolving co-references to character abbreviations (this is similar to the automated method employed by Trilcke et al. 2016, although the summary statistics that I extract are quite different).

Drawing on this tagged corpus, I create a social network for each drama and extract a series of summary features based on both the eigenvector and betweenness centralities of each play. The first summary statistic that I calculate is the Gini Coefficient of the eigenvector centrality. Originally designed to measure income inequality within an economic system, the Gini Coefficient is a single number between 0 and 1 that indicates how evenly a set of resources (wealth, income or, in this case, centrality) is distributed across a population (here, of characters. In the Gini coefficient measurement in the corpus at large (Figure 1), there is a clear historical pattern being played out. Over time, between 1550 and 1900, the Gini coefficients of the plays exhibits a clear downward trend, from plays with a small core and a large, non-central periphery in the early century, to plays with a relatively large core and a small periphery in the eighteenth and nineteenth centuries and a large discontinuity between 1650 and 1700. What this metric seems to indicate, then, is the disappearance of the periphery of the English drama over time. Rather than suggesting significant structural changes to the core of the play, the largest influence in the Gini coefficient is the presence of a large periphery, whose members rarely speak (and more importantly, rarely interact with the center of power) and who therefore bring down the Gini coefficient for the entire play. Over time, then, this periphery disappears as casts get smaller and actions take place among an increasingly more tightly knit set of characters. Servants, retainers, guards, acquaintances and messengers, so important during the early modern period, disappear with increasing regularity in the later periods, echoing the reduced function such figures had in society itself, as dramas move, following Habermasian logic, from the throne room to the drawing room, becoming personal and intimate, rather than mythic, political and impersonal.

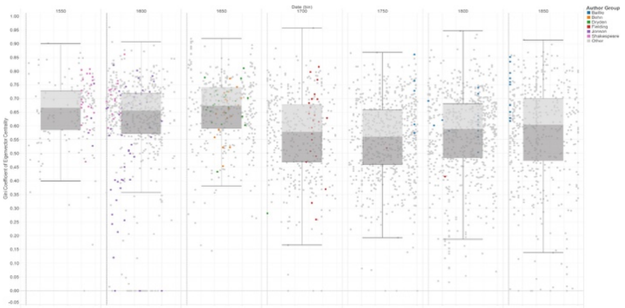

Figure 1. Gini Coefficients of Eigenvector Centrality over time. The corpus is divided into 50 year bins (with the plays in each bin arranged chronologically). Colors indicate selected canonical authors.

The second metric is the percentage of characters in the top quartile of the eigenvector centrality distribution. This measures the size of the core of the play and tells an equally striking and parallel story (Figure 2). Although the relative regularity of the measurement makes it less immediately apparent, there is a constant historical increase in the percentage of characters in the top quartile of eigenvector centrality scores. While the falling Gini Coefficients speak to the disappearance of the periphery, this metric reveals what happens to the remaining core. Rather than follow the same pattern of the early modern period (with few highly central characters), the disappearance of the periphery means that more centrality is allotted between the core characters. This speaks not just to the increasing size of the core, but, more importantly, to the tendency of having plays that feature multiple sub-networks, each with their own protagonist. In a play with a single network, it is easy for one character to dominate it, but in a play whose action is divided between competing communities, each community can have its own central figure. If we can tell the protagonist of an early modern drama by his or her high eigenvector centrality compared to the rest of the cast, then by the seventeenth century the single protagonist has been dispersed between multiple characters who all evidence a high eigenvector centrality, distributing the function of the protagonist (and/or the antagonist) among a growing number of central characters.

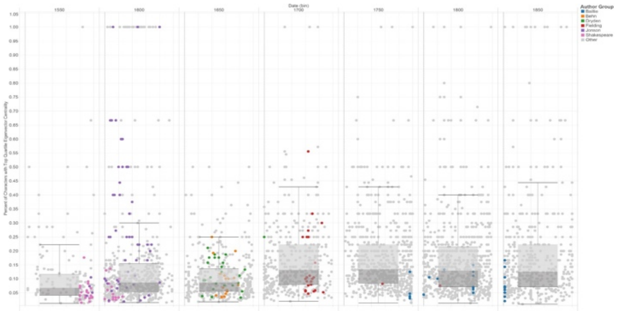

Figure 2. Percentage of characters in the top quartile of the eigenvector centrality distribution in the play.

As opposed to the eigenvector centrality's relationship to the protagonist, betweenness centrality speaks to the mediatedness of the drama. That is, if a high betweenness centrality indicates a character that mediates other character's interactions (such that they have to pass through her), then the scaled maximum betweenness centrality of a dramatic network overall, which measures the relatively importance of bridging characters, indicates the extent to which this mediating function is important to the drama as a whole. At the level of the corpus, the normalized maximum betweenness centrality, the relative importance of the bridging character, decreases across the century, very quickly from 1590 to 1640, and then more slowly across the remaining two and a half centuries: the average maximum betweenness centrality in a play drops by over 750 across just the sixteenth century. Again, the largest discontinuity lies between 1650 and 1700: there is a clearly a lasting effect on the structure of dramatic networks from the puritan shuttering of the theaters during the interregnum. The English drama that returns during the restoration is evidently not the same as the English stage before Cromwell.

Understanding Reader-Identified Social Interactions in Literature

Koustuv Sinha, Andrew Piper, Derek Ruths

Social network analysis begins with the primacy of character as its object of study. In this, it fits within an aready well-established area of inquiry within literary theory, one whose formal study extends back until at least the early twentieth century if not earlier (Propp 1968). Where social network analysis differs from this tradition is through the emphasis on *dynamic interactions* as a key to understanding the narrative function of character. Whether exploring the afterlife of fan fiction, theories of mind, affective identification, or the typologies of character, what all of the pre-computational work on character has in common is an emphasis on understanding character in the singular. Social network analysis argues instead that the meaning of any character is a function of his or her relationships with respect to all of the other characters introduced over the course of a story (Woloch 2009). Character networks offer a way to study not simply the types or themes or affective connections between readers and imaginary people. Rather, they afford us the ability to understand the social imaginings of writers, periods, and genres.

Several initial attempts to introduce social network analysis into the study of literature have already been made. Character networks have been studied within three major European epics to understand their relation to contemporary models of social networks (MacCaron/Kenna 2012); an abridged version of a single well-known literary work (*Alice in Wonderland*) to test differences between interactions and observations on character centrality (Agarwal 2012); nineteenth-century novels to understand the correlation between dialogue and setting (Elson 2010); as a form of narrative generation (Sack 2013); and the genre of classical drama to better understand the notion of tragic conflict (Moretti 2013; Karsdorp et al 2015).

Each of these works has added to our understanding of the relationship between character and literary form in important ways. And yet at the core of each of these studies lies a fundamental assumption about the self-evident nature of an "interaction." Initial attempts to use machine learning to derive interactions on prose texts have shown very poor performance (Agarwal 2012 reports a maximum F1 score of 0.61). What this indicates at least in part is that interactions are highly complex verbal constructions which we cannot easily assume pre-exist our attempts at extracting them.

To counter this problem, we have designed a study to explore reader agreement across a variety of text passages (1,000) drawn from popular contemporary fiction and nonfiction. Rather than begin with a stable set of interaction types, however, our goal is to infer possible classes of interactions and then understand which of these classes generate more ambiguity among readers. We perform this in three phases. In the first phase, we ask coders to identify minimally defined interactions using a standardized web interface (where an interaction consists of two entities and an action linking them). Our goal here is not to pre-define types of interactions as in other studies (Agarwal), but to better understand how readers intuitively understand social interactions between characters. As we have shown in another study, readers indicate very high agreement in identifying character aliases (i.e. determining what is an entity (Vala et al.)). In the second phase, we use unsupervised clustering techniques to identify different interaction "types" based on syntactic and lexical features of the labeled interactions. Third, we then measure reader agreement across these different types. While we want to know overall how well readers agree on defining interactions, we also want to understand if different types of interactions across different types of writing (fiction/non-fiction) illustrate signigicantly higher levels of disagreement. This is a first step in understanding the unique ways literary texts generate social complexity, not simply through the quantity of interactions but also importantly through their qualities.

Emma: A Feature Space for Studying Character

This paper will argue that computation has an important role to play in understanding the nature of characters and the process of what we might generally term characterization – the writerly act of generating animate entities through language. With an estimated 86 characters per novel in the nineteenth century and a conservative estimate of 20,000 novels published during this period in the English language, there are over 1.7 million unique characters that appear in that one century and one language alone. Even if we condition on main characters, we are still looking at several thousand distinct entities. At the same time, there are not only a great number of characters in literature, but there is also a tremendous amount of information surrounding even one primary character. Like other highly frequent textual features such as conjunctions or punctuation, characters are abundant across the pages of individual novels. Personal pronouns alone account for roughly 12% of all tokens, and if one adds in proper names the number of character occurrences is closer to 16% – or one in every six words! Like the abundance of characters, such semiotic abundance surrounding characters poses problems for inherited critical methods. How can we be sure that our claims about "character" are capturing the broad and potentially diverse ways that characters are depicted in novels, this larger mass of fictional beings and what it means to be fictional?

In order to address this question, we have developed a computational tool designed for the study of character. Its aim is to identify 28 different features that relate to qualities that characters may possess. These range across categories like distinctiveness (how distinctive is the main character from other characters within the novel); positionality (how often is the character the agent or object of a sentence or a possessor of some object); centrality (how important is the protagonist relative to other characters in the novel); and modality (what kinds of behaviors and descriptions inform this character's identity, such as cogitation, perception, motion, embodiment and even clothing or dress).

Rather than start with known "types" of character, this tool allows us to implement a more multi-dimensional understanding of character and use that representation to think about the relationships between novels. Prior work on stylistic analysis has not differentiated between various aspects of texts when comparing them to each other. The novel is taken as a unified whole. Our character feature tool allows readers to begin to explore these different sub-domains of a novel, which in our case refers to the language used to construct character. In our presentation, we will discuss the mechanics that underlie the tool, which implements a modified version of BookNLP (Bamman 2014) and the Stanford dependency parser in order to identify words related to character. We will also discuss a case study in which we explore the identity of "introversion" in novels from the nineteenth century to the present. As we will show, the character feature tool allows us to construct not only familiar narratives about the history of the novel – wherein the representation of interiority is strongly gendered around female protagonists – but also novel and nuanced insights about that tradition when we follow these features across a broader swath of time. As we will show, interiority no longer remains the distinctive quality of feminine heroines but is transposed onto a very different generic and gender scene – the male hero of science fiction.

Reconstruction –Representation –Collaboration: Interdisciplinary approaches to changes in contexts of digital (music) editions

Introduction

The field of Digital Humanities is characterized by complex questions and interdisciplinary discussions. That applies not only to the cultural science-based side of the humanities but also to the digital representation of cultural artefacts and, among other things, their processing, analysis, preservation and long-term availability. In order to handle these issues, interdisciplinary collaboration is required to pool and to coordinate expert knowledge and skills.

The Digital Humanities project ZenMEM (Centre of Music – Edition – Media) represents such an interdisciplinary project. Since September 2014, researchers from Paderborn University, the Hochschule für Musik Detmold and Ostwestfalen-Lippe University of Applied Sciences combine their expertise from musicology, various fields of computer sciences (contextual informatics, software engineering, usability engineering and music informatics) and media studies (media education and media economics) to investigate processes of change and new possibilities of the transition from analogue to digital music and media editions.

In this context, digitization can be discussed as distributed through material infrastructures and displayed on computer devices (cf. Huber 1998). But it can also be considered in non-physical dimensions. In this perspective cultures are containing specific structures that build a para-material quality (cf. Schrage 2006).

> "Writing is a material act; textual production in any medium has always been a part and product of particular technologies of inscription and duplication." (Kirschenbaum et al. 2009).

A third perspective can be discovered between these poles on the transition from material and immaterial (cf. Holl 2010, Manovich 2011, McGann 1991). The fourth dimension in this context refers to the fact that

> "Digital Humanities work embraces iterative, in which experiments are run over time and become object to constant revision. Critical design discourse is moving away from a strict problem-solving approach that seeks to find a final answer: Each new design opens up new problems and – productively – creates new questions." (Burdick et al. 2012)

Between these perspectives, we explore interdisciplinary approaches of digital (music) editions. First, the dimension of digital representation and the contents on the surface (cf. Manovich 2001). Here, the traditional Human Computer Interface (HCI) to digital editions is questioned and expanded to incorporate Computer Interfaces, ultimately demanding to "granting access to machines".

The second perspective focusses on the relevance of the user for all types of media (cf. Fiske 2001). In this view, we present a qualitative research study (cf. Denzin 2000; Przyborski & Wohlrab-Sahr 2009; Keuneke 1999) dealing with the changing work processes of musicologists and music editors in the context of digital music editions. These changes have, among other things, lasting impacts on their scientific research, orientation, academic ethos and knowledge building.

The third paper deals with the structural changes in scientific work in context of Digital Humanities. A growing number of interdisciplinary academic projects causes an increasing need for researchers with the key qualification "interdisciplinarity" as well as methods to verify the projects' efficiency and quality (cf. von Kardorff 2000).

The analysis of the complex interactions among these dimensions leads to essential issues of the digitization of (music) editions: The access to perspectives of digital representation, the impacts on scientific work and access to user views and at last a dimension of access to changing interdisciplinary project work within the Digital Humanities.

In case of acceptance, this multiple paper session would be presented by Bianca Meise (media education and qualitative research, Paderborn University), Peter Stadler (musicology, Paderborn University) and Franziska Schloots (media economy and management, Paderborn University).

Digital Editions and the Interface. Granting Access to Machines

Peter Stadler

Johannes Kepper

Daniel Röwenstrunk

The history of Digital Editions and its main driving force, the Text Encoding Initiative (TEI), is a success story. It not only enabled the digital presentation and preservation of scholarly editions but subsequently facilitated further research on this digital material and the development of tools and methods, pushing forward the DH sector as a whole.

The TEI puts a lot of effort into its (prose) Guidelines and the formal specification of the schema(s) – it ultimately developed a meta language (ODD = One Document Does it all) for the definition and documentation of TEI schemas and customizations, leading to a well-documented, highly flexible interchange format. "This is standardization by not saying 'Do what I do' but instead by saying 'Do what you need to do but tell me about it in a language I understand'." (Cummings 2013)

The Music Encoding Initiative (MEI) adopts these principles, empowering it to encode a wide variety of musical styles and genres through its modular approach. Yet, a long-standing issue with the resulting XML documents is the lack of interoperability. True interoperability would allow the 'blind' reuse of files within one's own processing chain (cf. Bauman 2011). But due to the TEI's and MEI's flexibility of encoding even the (assumed) simplest operations can hardly be processed blindly, e.g. the extraction of a plain text version (aka the "throwing away of angle brackets") or the extraction of a single voice from a score.

Generally speaking, digital editions are potentially multifunctional and enable multiple views on the text (cf. Sahle 2013; Pierazzo 2016), yet this potential can hardly be activated from the outside but has to be revealed by a standardized endpoint or interface. Most commonly, the only (public) interface of a digital edition is the HTML version accessible online with a (Javascript enabled) browser. Different views are created from one TEI source file and prepared for a human reader, e.g. a “Semantic Edition” or a “Philological Version” (for example, see the respective tabs of the letters published on Burckhardt Source). While this interface and its functionality is adequate and pleasing for a human agent, it’s more or less useless for a machine agent which would have to grab the web pages and parse idiosyncratic flavours of (X)HTML(5). Only a few digital editions offer the direct download of TEI encoded files and even less offer a dedicated (and well documented) interface for machines.

Within the ZenMEM and ViFE research infrastructures we are trying to remedy this shortcoming of digital editions by developing dedicated APIs for our projects. We believe that this has at least two advantages:

1. intrinsic: better documentation of our own work
2. extrinsic: facilitated reuse of our work by others

These project APIs are developed and documented using the Swagger framework and the resulting configuration files can be found on Github. Along with those project specific APIs we strive to develop a meta API with a core set of functions which are to be supported by all projects. There is an ongoing discussion on what these core functions are – especially since we are dealing with various materials, from music to text encoding, from placeographies to bibliographies, from sketches to prints. On the other hand, we are confident to come up with a set of generic functions that could then easily be adopted by other projects. With these interfaces to digital editions we will finally leave the traditional resource based approach to digital editions behind and move on to a new functional, truly dynamic approach.

A changing paradigm? Implications of digitization on musicologists work on editions

Bianca Meise

Digital Humanities are focusing on digital data. Therefore, issues on modelling, representation, analysis and annotations are crucial dimensions of research like processing and archival storage. But digital data and the procedures quoted before are used by editors and have impacts on their scientific work, too (cf. Edwards 2012). This contribution is focused on an access to the editors as special user and producer group in the process of digitization through a qualitative empirical study. In this study, it is neither the editor nor the data alone, rather, it is the act of editing, analyzing, representing and annotating that gives insights into the relation between media, material and subjects that allow deep insights into the transformational impacts of digitization. First, I discuss the changes of the scientific working process from analogue to digital. Secondly, the challenges and potentials of this change of paradigm will be discussed. At last, as a result of these findings, the future inquiries of digitization of music editions, changes of work processes and not least the education and varying access to knowledge work will be pointed out.

Digital music editions have a lot of potential for editors, scientists and recipients (cf. Veit). Thus, the digital availability accelerates and arranges the editorial scientific process. Furthermore, the different representations of the digital offer a great transparency and confirmability. In this perspective, the digitization of music editions enriches the work of musicologists (ibid.). A lot of issues are discussed in context of digital humanities refer to the digital representation or the transformation of cultural artefacts, their further analysis and processing. These subjects are considered on data. The work, examination and handling of the digital and the influences of the knowledge evolving within is discussed less. In this contribution, the formal layer (cf. Kirschenbaum 2008) or cultural layer (cf. Manovich 2001) and moreover the performative interactions between the material and the subjects will be considered (cf. Drucker 2013). Issues like the challenges to adopt digital techniques, to prepare digital sources, to represent and analyze them are important, too. The examination of the various practices of adoption, handling and orientation offer deep insights into the possibilities of digitization and its relevance for scientific work. This study allows a rare attendant insight in the transformation of a media paradigm in music philologists’ work.

The editions contain different types of "texts" like several notation formats, facsimiles, born digital annotations, text and audio files. Before digitization there are analogue procedures of searching, collecting, arranging and reviewing. Since the digitization of music editions, the shift is not only digital. Moreover, it’s both digital and analogue, material and corresponding practices, that construct the editions. It is the operation, the handling of the musicologist with cultural, material and immaterial artefacts. To develop the importance of media and the corresponding methods in digital music editions, its necessary to explore these various interactions. Like the radical contextualization of the cultural studies pointed out that object and subject, media technology and context (cf. Winter 2010) continuously affecting each other and be interwoven.

Based on the qualitative research perspectives of the Grounded Theory Methodology (cf. Strauss & Corbin 1996; Denzin 2000, Przyborski & Wohlrab-Sahr 2009) in this study eight narrative guided interviews with problem-centered parts have conducted. Because of the academic void of the user perspective qualitative research offers great potentials to get essential insights and generate first hypothesis in this field (cf. Flick et al. 2000). The investigation on varying routines or the knowledge of the musicologists even if it's implicit (cf. Polyani 1985) is not simple to transfer in direct questions. In fact, the qualitative research provides many methods to manage this problem (cf. Flick 2002). The guided interview is an inquiry method that follows a structure, but allows a lot of free space for further situated questions and narrative answers (cf. Keuneke 2000). The questions are focused on the routines of the working process of music philologists, their evolving (implicit) knowledge and their biographical reference points to music editions. The qualitative material has been analyzed by a modified coding version of the grounded theory (cf. Strauss & Corbin 1996) like Przyborski and Wohlrab-Sahr (2009) pointed out.

The empirical data and their interpretation documented, that the change in the working process in not only a shift from analogue to digital. Moreover, the hole scientific process is changed and the work on digital music editions have deep impacts on editorial, juridical, organizational, social and not at least educational processes. Digitization changing the scientific work organization, the editorial work and the perspective on editions and the interwoven knowledge.

Interdisciplinary research and knowledge building – Development of recommendations for action for academic projects in the digital humanities

Bianca Meise,

Franziska Schloots

Jörg Müller–Lietzkow

Dorothee M. Meister

The heterogeneous research field of digital humanities is characterised by a high level of connectivity and interdisciplinarity. Not least because of this the digital humanities turned out to be a dynamic field with high velocity of scientific discourses (cf. Gold 2012). In this context, the development of research infrastructure for interconnected and collaborative scientific work (cf. Reichert 2014) as well as the management of interdisciplinary research projects represent particular challenges. Whereas especially the economically characterised management research (cf. Bea, Scheurer & Hesselmann 2011/ Steinmann & Schreyögg 2005) deals with project management processes in companies, network groups or other cooperation forms, project management in academic contexts is hardly found in research literature. One important distinctive feature, especially for academic projects without industrial partners, is that the goal dimension of academic projects fundamentally differs from economic projects. Its focus is not a typical measurable economic gross profit or other definable objectives. The openness for results as an important part of scientific research requires a modified form of project management. However, strategic and systematic project management is hardly implemented in the structure of universities, particularly in cultural science departments and projects. Oftentimes, a rather “muddling through” (Lindblom 1959) can be noticed. This is not a desirable condition because consequences might be increasing transaction costs as well as reduce chances for long-term and stable research collaborations. Furthermore, the special structures in academic contexts must be considered concerning the planning, implementation and organisation of collaborative interdisciplinary projects.

In view of these conditions, the importance of professional project evaluation is evident, especially in interdisciplinary projects involving cultural scientists as it is the case in digital humanities projects. Digital humanities can be seen as an extension of the complexity dimension according to Rinza (1998): A high scientific novelty grade is associated with an increased risk for the project goals and a relatively large project group might increase the dependencies in the work processes because of the close interlocking of the individual departments.

The growing concentration of interdisciplinary academic projects causes an increasing need for scientifically verified evidence of their efficiency and quality (cf. von Kardorff 2000). For this purpose, summative evaluations are used to review the effectiveness and the achievement of defined targets as well as formative evaluations which can contribute to the optimization of an ongoing project and can provide the basis of strategic decisions and changes (cf. ibid.). Within this paper, the procedure will be clarified through a concrete case study from the field of digital humanities.

In the project ZenMEM (Centre of Music – Edition – Media), a formative evaluation in the ongoing project was conducted so its results could be used to develop recommendations for action for the further process.

In ZenMEM, researchers from Paderborn University, the Hochschule für Musik Detmold and Ostwestfalen-Lippe University of Applied Sciences investigate processes of change and new possibilities of the transition from analogue to digital music and media editions since September 2014.

The project is initially promoted for three years by the German Federal Ministry of Education and Research (BMBF) and combines experiences and expertise as well as concepts and methods from musicology, various fields of computer sciences (contextual informatics, software engineering, usability engineering and music informatics) and media studies (media education and media economics). The focus of their research is on musical and other non-textual objects in context of digital editions. In this sense, the researchers are able to link to their preliminary scientific work as well as international developments like the Edirom project or the standards of Music Encoding Initiative (MEI) and Text Encoding Initiative (TEI) . They participate in its further development and examine innovative interacting and editing functions for the creation of digital music and media editions. In addition to research work, corresponding software tools are developed, technical advice and coordination is provided to external projects and training activities in form of workshops, courses and lectures are conducted and further developed. These steps are being accompanied by qualitative and quantitative user studies which take the entire creation process of digital editions into consideration. The results flow back into research and development work within the ZenMEM center. This short project description gives an impression of the complexity of the tasks in this joint project and the amount of heterogeneous research questions the cooperation partners are dealing with.

To conduct a formative evaluation for the ZenMEM project in order to develop recommendations for action for the further project progression, a qualitative half-standardized written survey was chosen as research method. For this purpose, a questionnaire with 18 questions was given to all project members. These questions were relating to previous experiences with working in interdisciplinary projects, special challenges within the project, specific work packages and personal goals. In the last section, the researchers were asked for valuation of ongoing processes and constructive suggestions for improvement. In addition, a shorter questionnaire was sent to the project leaders. Thus, the perspectives of different project status groups could be surveyed.

For the analysis of the results, amongst other things, a categorization based on the concept of SWOT analysis was performed. Developed at Harvard Business School in the 1960s for the strategic planning in companies, the SWOT analysis is a versatile tool (cf. Schawel & Billing 2009) describing the strengths, weaknesses, opportunities and threats of any company or project which constitute a basic structure for developing strategic recommendations for actions (cf. Kotler, Berger & Bickhoff 2016). To derive concrete statements from these four dimensions, the categorization had to be refined. Regarding the evaluation method of coding with Grounded Theory (cf. Przyborski & Wohlrab-Sahr 2009) a differentiated categorization within the root categories was performed.

In this context, it is important to note that Grounded Theory is a methodology as well as an evaluation method (cf. Strübing 2004). The paper at hand focuses on Grounded Theory as an evaluation method to collect phenomena, condense them into concepts, identify categories and uncover connections between them. Following, recommendations for action could be worked out from the combinations of single phenomena in order to optimize processes within the project. Furthermore, indications could be provided to identify which actions should be focused and which should be avoided (cf. Pepels 2005). Individual competences of the project participants were also taken into consideration. Among other things, it became clear that interdisciplinarity in such a project can be considered as both opportunity and challenge, especially regarding the different preconditions, approaches and methods. People not only hold various paradigms and epistemological interests but also act within different organizations and social systems – nearly all university departments and courses are oriented mono-disciplinary (cf. Dressel et al. 2014). Stringent guidance is needed to enable successful interdisciplinary research. In the ZenMEM project, superiority of the subject disciplines was at least a little bit softened and reflected by mutual work observations as well as agreements on certain terminology so that a basal equality of the participating research partners could be established and constantly evolved.

While in this case, systematic knowledge building took place directly from within the project, it can be discussed how the mediation of interdisciplinary competences could be implemented a lot earlier. As already indicated, interdisciplinary collaborations in academic contexts are of increasing significance and the demand for qualified young researchers with the key qualification interdisciplinarity (cf. Mainzer 2013) grows. More and more universities offer degrees in digital humanities or related fields. However, corresponding curricula show very different weightings of cultural science-based or computer science-based contents (cf. Schubert 2015). A closer inspection of digital humanities projects and a comparison between project experience and curricula might be helpful to develop degree courses so that interdisciplinary competences and shared knowledge can be gained.

Introduction

Access, in all its iterations, continues to shape the discourse of digital scholarly editing as the field grapples with new models and methods. Our proposed 90 minute panel will frame a discussion around a broader definition of the concept in relation to the field of digital textual scholarship, by critically reflecting on its meaning for Digital Scholarly Editions (DSEs) and theorizing how the term relates to issues of accessibility, usability, pedagogy, collaboration, community,and diversity. Each of the fellows will make short '7-14-28' presentations (seven minutes for 14 slides in 28-pt font), identifying results and questions arising from our research over the last three years and leaving 48 minutes for discussion. Refining our concept of access signifies a valuable contribution to the field: while 'accessibility' is a highly-cited term in digital editing, its use generally refers to making data (Sahle 2014) and source materials (Martens 1995: 222) more openly available rather than to making data more understandable to different types of users, including users with disabilities. Similarly, discussions regarding different user needs typically refer to those with a non-academic background (e.g. Apollon et al. 2014: 93; Pierazzo 2015: 151), rather than users with (in)visible disabilities.

Accessibility and Usability

The digital medium gives the DSE the capacity to be more accessible than its predecessor. Automated analysis and the processing of algorithms allow for the development of a host of tools useful to people with disabilities. Existing tools like screen magnification software or Text To Speech software , for example, already help people with visual impairment to better absorb and navigate the edition's contents. But such ready-made user-dependent solutions only scratch the surface of the ways in which we can make our editions more accessible to people with both visible and invisible disabilities. When designing a web interface for DSEs, current accessibility standards in web design are rarely taken into account — if indeed at all. The mere fact that two major points of reference in our field (Sahle 2014; Franzini 2016) do not mention accessibility in their respective lists of criteria already implies that standards such as @alt texts for links and images, consistent use of header tags, legibility of fonts, attentive use of colors and contrast, etc. are not sufficiently acknowledged or adopted. As editors, perhaps our preoccupation with the underlying XML of our editions has lead us to be less conscientious about our use of the transformed HTML. In this respect, we could follow the example set by the World Wide Web Consortium, which has made a considerable effort in encouraging an increased coordination between the interrelated concerns of accessibility, usability, and inclusion in web design (W3C 2016).

Usability is inextricably linked with design approaches and practices, both in terms of functions and aesthetics. Ruecker et al. (2011: 13) argue that aesthetic design promotes the perceived usability as well as the perceived value and legitimacy of digital cultural heritage materials. Editing projects can develop these skills internally as part of a change in pedagogy, or, in order to strengthen a community of practice and knowledge transfer, can develop them in collaboration with other disciplines, libraries, and private sector partners. Measuring usability and access can also be gauged through opportunities for reuse. This would involve determining the extent to which edition data is made available for open access and what type of licensing information for potential re-use is communicated to the user. Mapping the W3C's standards onto the practice of scholarly editing is not only a good way of supporting the community of people with disabilities, but also a constructive way to confront the digital divide and generally benefit users of DSEs.

Pedagogy and Collaboration

As new publication models emerge in this developing field of scholarly research, practitioners are continually expected to readjust their skillsets. Pierazzo (2016) noted that the role of the editor has changed significantly in the digital medium, growing from advanced awareness of classical theory to the 'super-editor' model with added requirements of technical skills including understanding of front and back-end web design, image processing, XML, specialized scripting languages, etc. In an environment where these skills are not only desired but also expected, aspiring editors spend significant time and money on acquiring them through workshops, courses, and prolonged research stays, in which specific projects provide opportunities for in-depth training as well as valuable networking opportunities.

Acknowledging our place of privilege in this debate as the recipients of a European research grant, we would argue that while our network's practice of sponsoring conference and workshop attendance for non-DiXiT early career researchers is a necessary first step, it may not be enough: we also need to rethink the way these courses are offered, and to to develop best practice documents for training new editors. To accomplish this, we need to ask ourselves whether we want to focus on a broad and comprehensive skillset with an overall understanding of concepts and principles, or accept a specialisation ethos that invites more collaborative work. Our own training has primarily involved literary or historical materials using the latin alphabet and reflecting dominant editorial schools, traditions, and scholarly disciplines. Indeed, the majority of the training material produced for digital editing (workshops, seminars, books, guidelines, etc.) is produced in English or in western-European languages, thereby excluding scholars from smaller communities from fruitful engagement with the field. How do we actively promote a more inclusive approach both to the content of editions and to the training of future editors? Can we adopt a vantage point that justifies the inclusion of and training in a variety of disciplines, without diminishing the value of highly specialized knowledge?

Community and Diversity

Overwhelmingly, DSEs have focused on the documents and narratives of western-European and North American males (for example, the catalogues of Sahle (2016) and Franzini (2016) predominately feature this demographic). We need to be critical in asking ourselves hard questions about our assumed audience, gender-equity and social justice, and which narratives we are gatekeeping by choosing these texts. Given that our editions increasingly do not reflect the gender array of our practitioners, a reorientation toward underrepresented voices is called for. This is modelled by digital libraries and archives, which offer significant collections about women's history, LGBTQIA culture, people of color, indigenous peoples, and people with disabilities. It would behoove digital editors to follow the example set by our collaborators and seek out opportunities to expand the canon, attributing the same care and attention to texts produced by these groups.

Finally, along with thinking of ways to expand the canon of scholarly editions, we also need to reflect on new ways to diversify the community of scholarly editors — which, like its subject, could also be characterised as a predominantly white, Western-European or North American male community. Bordalejo (2016) presented a similar argument about demographics in DH that could easily be extrapolated to our subfield. In a recent paper Robinson (2016) called for a reconsideration of the role of editors and scholars by taking a more social approach whereby these academics should become 'key participants in, and enablers of, communities' rather than leaders of more exclusive collaborations. This encourages us to reflect thoughtfully about how digital scholarly editing is conceived and performed as an elite activity, accessible mostly to researchers and communities with sufficient financial, infrastructural, and societal means to support them. If we recognize this, how can we encourage a more inclusive approach?

On the Panel

The Digital Scholarly Editions Initial Training Network (DiXiT) is a Marie Skłodowska-Curie EU-Funded 7th Framework Programme. During the grant period (2013-2017), twelve Early Stage Research Fellows and five Experienced Research Fellows engage with questions and tensions surrounding the evolving theory and practices of digital scholarly editing. As our projects draw to a close we are reflecting critically on how we have examined and contributed to the changing nature of digital textual scholarship. With access being such a pertinent issue to the field of digital textual scholarship, we hope to stimulate a lively and productive conversation with the audience around these interrelated themes.

Building Capacity for Digital Scholarship & Publishing: Three Approaches from Mellon's 2014-2015 Scholarly Communications Initiative

Sara Sikes
sara.sikes@uconn.edu
University of Connecticut, United States of America

Maria Bonn
mbonn@illinois.edu
University of Illinois at Urbana-Champaign
United States of America

Elli Mylonas
elli_mylonas@brown.edu
Brown University, United States of America

The Andrew W. Mellon Foundation's 2014-2015 Scholarly Communications Initiative funded more than thirteen projects of various sizes and orientations as part of an effort to strengthen the scholarly monograph publishing ecosystem in a time of increasing disruption. While the projects are seemingly divergent in their approaches, a recent report from Simon Fraser University, "Reassembling Scholarly Communications: An Evaluation of the Andrew W. Mellon Foundation's Monograph Initiative" (May 2016) identifies points of thematic alignment and overlap. Many of the funded projects are explicitly based in university presses, with the goal of either enhancing existing monograph programs or developing digital capacity where little or none exists. But three projects, located at University of Illinois, Brown University, and University of Connecticut, are instead focused on exploring new forms for scholarly expression and developing models for faculty digital publication outside the traditional press framework.

The "Building Capacity for Digital Scholarship & Publishing" panel brings together representatives from each of these three projects to investigate unique and complementary dimensions of their work. Presenters include Maria Bonn from the University of Illinois, Elli Mylonas from Brown University, and Sara Sikes from the University of Connecticut. The session will address the development of project outcomes and encourage participation in a discussion about large-scale shifts in structural and cultural approaches to faculty-led digital scholarship production and publication. Rather than building new publishing platforms, these three Mellon-funded projects are focused on exploring workflows and work cultures suited to the creation of multimodal scholarly communications. The University of Illinois will explore how current tools align with scholars' publishing requirements and address the gap between scholars' needs and the existing publishing systems for digital scholarship. At both Brown University and University of Connecticut, the scholarly publications initiatives are focused on developing an infrastructure to support digital scholarship projects, facilitating new workflows and work cultures, and revising criteria for tenure and promotion.

Publishing Without Walls

Maria Bonn

"Publishing Without Walls" is a Mellon-funded initiative at the University of Illinois, led by the University Library in partnership with the School of Information Sciences, the department of African American Studies, and the Illinois Program for Research in the Humanities. The objective is to develop a model for library-based publishing services that can be adopted broadly by other academic libraries to address scholars' emerging needs in a contemporary publishing environment. Both an embedded research effort and programmatic development are strategically designed to address known gaps within the current landscape: the gap between what and how scholars want to publish and what existing systems of print publishing can afford; the gap between the everyday practices of humanities scholars and the high-level tools that exist for digital scholarship; and the gap between digital scholarship and publishing at resource-rich institutions as opposed to at Historically Black Colleges and Universities.

Most experiments with new forms of and models for digital publishing focus on parts of the process rather than taking a holistic, scholar-centric view of publication: for example, tools are often developed with only an abstract sense of scholarly requirements, and new funding models are suggested without exploring whether and how existing systems meet scholars' needs. In order to guide the development of a more holistic and widely shareable service model, the University of Illinois is undertaking a significant qualitative study on how emerging services and tools align with scholars' publishing needs and using the findings to shape and inform the development of tools and services for Publishing Without Walls.

The Role of the University in Scholarly Communication

Elli Mylonas

The purpose of Brown University's Mellon-funded digital scholarship initiative is to establish an infrastructure to support the development and publication of digital scholarly monographs. Anchored in the University Library and the Office of the Dean of the Faculty, this digital publishing initiative extends the University's mission of supporting and promoting the scholarship of its faculty, while also playing a role in shaping the future of digital scholarship in the humanities more broadly.

Brown will first address questions about the evaluation of digital scholarship within the academic validation process. The initiative promotes the creation of language and criteria at the department level upon which digital scholarship will be evaluated for tenure and promotion purposes, and this process is, as of Spring 2017, substantially complete. With these guidelines established the initiative is now supporting two digital scholarly publications. Mellon grant funds have been used to augment the library's staff, adding new positions including the Digital Scholarship Editor, a Designer for Online Publications, and graduate- and undergraduate-level researchers. Funds from the grant are also designated to bring in speakers who are engaged in digital projects or other efforts to introduce digital scholarship and publication into the formal academic process in order to spark discussions around best practices and innovative approaches. By tackling first the issue of evaluation and then assisting with the creation of innovative, digital-first scholarship as well as innovative digital publication, the initiative will remove barriers in place at Brown and potentially serve as an example to other institutions that are engaging with emerging forms of writing, publication, and dissemination.

The Scholarly Communications Design Studio

Sara Sikes

The Digital Media & Design Department at the University of Connecticut (UConn), in collaboration with the University Library and UConn Humanities Institute, is implementing Greenhouse Studios | Scholarly Communications Design at UConn. Greenhouse Studios will facilitate a design-based, inquiry-driven, collaboration-first workflow that addresses the divided processes and counter-productive labor arrangements that have complicated scholarly communications in the digital age. Even as the scholarly communications field pursues the opportunities presented by digital technology, its routine operations remain anchored in print-centric regimens. For those striving to evolve digital scholarship production and publication in the Internet age, particularly as it bears upon long-form scholarship, there is compelling need to productively disrupt and reconfigure the processes and work cultures that have naturalized around the production of printed products.

The proposed approach of Greenhouse Studios is undergirded by design-thinking methodologies that foster divergent creativity in generating and developing ideas directed toward solving complex problems while keeping end recipients of a project squarely in mind. Design thinking practices do not, in and of themselves, address cultural or workflow hierarchies, therefore a refined design process model has been established so that work begins with a prompt, an inquiry-in-common, that is set before a project team. In the design process model for the Mellon initiative undertaken at UConn, the potential audiences of a publication are explored at the very outset of a project, in specific rather than vague terms, as an essential element of the workflow. The team members hail from the areas once conceived of as the transactional links in the scholarly communications process, including librarians, web developers, editors, and designers, and they are assembled as a collaborative unit at the very outset of each undertaking. The power of the values and ways of working to be instantiated through the Greenhouses Studios places continuous, equitable communication between all kinds of scholarly communications labor at the heart of its mission.

In its broadest sense, "scholarly communications" is conceived of as communication of scholarship to specific audiences in a manner designed to make the expression of knowledge informative, useful, and relevant to that particular community. By employing the use of multimodal communications, researchers and their scholarship are connected to broad peer or public constituencies, and a work may be expressed in multiple form, each tailored to a different type of audience. As we look beyond inward-focused text, the visual, aural, and interactive forms of expression open pathways into understanding complex material that print alone cannot.

When we invoke the Digital Liberal Arts, we are not so much proposing a field that is by definition distinct from Digital Humanities—after all, both terms are notoriously subject to endless re-definition and contestation. Instead, we mean to strategically (and politically) call attention to the kinds of digital scholarship and pedagogy that are being conducted outside of traditional Research 1 institutions with well-funded DH centers. What conjoins our papers, then, is not so much that they present a series of new case studies in teaching with the digital: many people, we agree, could do that. Rather, we intend to prompt discussion and reflection about the kinds of infrastructures that are necessary (and perhaps not necessary) to produce sustainable and meaningful digital scholarship. Early on, Pannapacker proposed that small liberal arts institutions and programs might be uniquely positioned for rapid, more cost-effective innovation, because we have "shallower administrative hierarchies and less institutional inertia." (Pannapacker 2013) All of us hail from programs that "share a culture of faculty-student collaborative research, which translates perfectly into the project-building methods of the digital humanities" (Pannapacker 2013).

For these reasons, we are pondering the differences between large university DH and small college DH: a diffuse, decentralized approach to DH versus a more systematic and integrated one. Our varied papers share several connecting themes: collaboration across disciplines, roles and institutions; and the central place of pedagogy. The idea of pedagogy is critical to the mission of liberal arts colleges, and thus will feature prominently in this discussion. We place pedagogy at the center of all our work. There is much that larger institutions can learn from this discussion, including ways to make DH more student-centered and pedagogically oriented. Without romanticizing student-centered projects (we will also address some of the challenges for public scholarship with such a variety of skills at the table) we want to explore how involving students in the co-production of knowledge – digitally mediated and publicly presented – shapes and reshapes what is possible under "DH."

Over the last several years, spatial humanities have grown in prominence. Initiatives such as the University of Virginia's Institute for Enabling Geospatial Scholarship and Stanford's Spatial History Project have signaled and begun exploring the impact of the spatial turn. Writing for UVA's institute, historian Jo Guildi states, "The spatial turn represents the impulse to position these new tools [i.e. GIS] against old questions" (Guildi, 2010). In this panel, we challenge the idea that the spatial turn simply asks old questions and rather argue that it helps pose new as well as answer old questions in twentieth-century American history. In particular, we employ the idea of deep mapping as theorized by historian David Bodenhemer to discuss new scholarship and directions in digital spatial analysis. We also explore the role public humanities plays in framing these projects. The 45-minute panel entitled "Mapping the 20th Century United States" will focus on the role of the spatial analysis in the digital, public humanities and its impact on historical scholarship.

Robert Nelson will begin the panel with "Reckoning with Redlining: Public Engagement with 'Mapping Inequality.'" The Mapping Inequality project provides unparalleled access to the infamous redlining maps and area descriptions created by the Home Owners' Loan Corporation during the Great Depression. Accessed by tens of thousands of visitors in the first two weeks following its release, this paper will draw upon hundreds of contributions to a public conversation about redlining and urban inequality around "Mapping Inequality" in social media and the comment threads of press the project has received. Nelson will analyze the design decisions he and his colleagues made to prompt public engagement with these maps and the history of redlining. He will also critically use the reaction to the project to critically assess how successful this public-facing digital humanities project has been in prompting productive conversations about redlining and urban and racial inequalities.

Continuing with our exploration of the 1930s, we will turn to Taylor Arnold and Lauren Tilton who will discuss combining archives spatially in order to produce new knowledge about and public access to documentary expression in the era. They will focus on layering the Federal Writer's Project, which documented through text the life histories of thousands of Americans, with 170,000 photographs from the Farm Security Administration-Office of War Information. Placing these archives for the first time in conversation, their deep maps incite new questions about the role of the federal government in documenting the lived experiences of Americans during the Great Depression and the types of representation produced.

Next we will turn to the work of Jason Heppler on post-war America. Silicon Valley represented one of the twentieth century's greatest modernizations of urban space. Beginning in the 1950s, the formation of a new high tech suburbanism led the Valley to become identified not only with a center of hopeful possibility as the Industrial Age industries of the Midwest and Northeast began to decline, but also gave expression to an environmental politic that attempted to reconcile an environmentally conscious pursuit of the American Dream. Yet the claim for high tech's "clean" industrialization fell short as environmental concerns -- ranging from controlling growth to widespread chemical contamination of water supplies -- reshaped discussions about public and private space. Deep maps help explore the transformation of urban space over time.

Along with addressing the role of spatial analysis in cutting edge humanities scholarship, each paper will outline which technologies they are using along with their possibilities and challenges. In particular, Robert Nelson will address a cutting edge spatial toolkit the University of Richmond Digital Scholarship Lab and Statmen Design are developing for use across the digital humanities. The panelists will also discuss the role of collaboration, the process of developing cross-institutional partnerships and designing for public audiences.

Reckoning with Redlining: Public Engagement with "Mapping Inequality"

Robert Nelson

In keeping with the conference theme of access and its emphasis upon public-facing scholarship, this presentation will reflect upon hundreds of comments and several conversations from the lay public about "Mapping Inequality". A collaboration of teams at four universities, "Mapping Inequality" currently includes nearly all of the more than 150 "security maps" and nearly 10,000 "area descriptions" created by the Home Owners' Loan Corporation during the Great Depression. These maps assessed mortgage risk for thousands of neighborhoods in U.S. cities large and small on a scale of "A" to "D". "A" neighborhoods were deemed "best," presenting minimal risks for banks and lenders; "D" neighborhoods were deemed "hazardous" for mortgage financing.

	1930	1940
Population	458,762	494,537

Grading in Terms of Area: 5% 9% 40% 45%

Grading & Density Outward from City Center

These grades were explicitly racialist and racist. HOLC's survey instruments asked local agents to quantify the "infiltration of" undesirable populations of African Americans and immigrants. To cite just a few examples, a small subsection of a Tacoma neighborhood was graded "D" though otherwise identical to the surrounding "B" neighborhood because "Three highly respected Negro families own homes and live in the middle block of this area facing Verde Street. While very much above the average of their race, it is quite generally recognized by Realtors that their presence seriously detracts from the desirability of their immediate neighborhood." Proximity to black neighborhoods was enough to impact HOLC's risk assessment. A subsection of a neighborhood in Richmond was graded "C" rather than "B" because "Respectable people but homes are too near negro area D2." In contrast, a Camden neighborhood kept an"A" grade despite bordering an African American neighborhood, but only because "High walls separates this section from the colored area to the south" that effectively prevented their "spread."

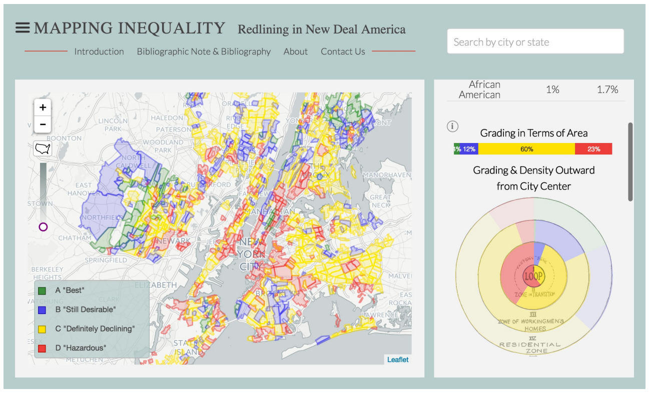
(Over)

These grades had real consequences. Through this HOLC program, the federal government reinforced redlining as a best practice within the real estate industry, in effect cutting off hundreds of thousands of African Americans off from equitable access to mortgage financing and thus homeownership, which arguably was the most significant mechanism of familial wealth accumulation in twentieth-century America. While of course it is by no means the only or even primary cause, this redlining program helped to contribute to generational wealth disparities between white and black Americans, where today the median wealth of white households is a shocking 13 times that of black households.

We designed "Mapping Inequality" not only with researchers but activists and the general public in mind. More than 150 of the HOLC maps have been georectified (nearly all of them, though we still have a few to add and undoubtedly a few more will surface), and polygons for each neighborhood added. The site is location aware and asks new users if they want to view their, or alternately the nearest, city. The opacity of the raster maps can be adjusted to help viewers connect the grades to the contemporary cityscape.

Nearly all of the neighborhoods polygons can be clicked to read the area description survey. In short, we designed it hoping to encourage viewers to grapple with the materials related to their own localities and to prompt them to make connection to the present.



The introduction and other contextual materials on the site convey the authors' collective assessment that "New Deal era housing policies ... helped set the course for contemporary America." We also include a visualization inspired by Ernest Burgess's concentric circle theory to suggest that HOLC policies definition of the interior of cities as "slums" functioned as a self-fulfilling prophecy. Nevertheless, the site prioritizes access, exploration, and reuse of these important primary source materials. We do not provide these materials completely without commentary, but through our design choices we do facilitate and encourage relatively direct engagement with HOLC's maps and surveys.

All of these materials were available in the National Archives. While materials for many cities had been digitized, to date there has been no comprehensive collection let along one offering the functionality of "Mapping Inequality." We have no doubt that these materials will be useful to researchers--not just historians but economists, urban planners, artists, medical doctors, etc.--and will facilitate a far more nuance understanding of HOLC and its consequences. We also have abundant evidence that these materials are a boon for activists working on fair housing and other social justice causes as well.

While we're excited about this, we intentionally developed the site as a public history project that aimed to spark conversations about wealth and racial inequality in American cities past and present. By that measure, the project so far has been a success. Two and a half weeks after being released, the map has received about 44,000 visits and been the subject of online coverage from NPR, National Geographic, Slate, CityLab, FastCo., Forbes, and Curbed, all of which have narrated the state's role in fostering redlining and wealth inequality.

In the comment section of these stories, in stories in local news sources, and in social media there has been a broad-ranging conversation about wealth and racial inequalities. On one of the spectrum, some respondents have been dismissive of the project, suggesting that this happened 80 years ago and is a remnant of the past that has little relevance today; one person notably characterizing the site as nothing more than "historical racism porn." Others have responded to such comments that this is important inasmuch as many of these 80-year old maps resemble the racial and class landscapes of America today and that the government's role in reinforcing redlining and racial disparities of wealth isn't widely understood.

Beyond these arguments about the impact of HOLC and relevance of redlining for understanding inequality in twenty-first-century cities, some of the most interesting and revealing comments have come from people for whom the maps have prompted reflection upon their own family histories. "I grew up in Detroit in the late 50's and 60's," one man wrote. "My address was 20400 Monte Vista, the corner Monte vista and Norfolk. Two streets east, starting at the corner of Birwood and 8 mile, was a wall. The wall was 12-15 feet high, made of grey concrete blocks and ran behind the homes towards 7 mile, extending to an abandoned army base at the corner of Pembrook and Birwood. The wall was built to divide the neighborhoods, one side was all African Americans, The other all Caucasian. My mother lived on one side of the wall, it was all African American. She once (just once) told me that one could hear the White families on the other side of the wall talking, see them occasionally if a ball came over the fence and they asked for it, most times they did not. One had no contact, ever. The wall is still there, physically and emotionally." While so far this story is rather exceptional in its detail, it has prompted us to think about the possibility of using the site to solicit and collect stories about the consequences of redlining and segregation on particular individuals, families, and communities.

Given that "Mapping Inequality" has been at the center of several online conversations and hundreds of comments on websites two and a half weeks after it was first released, I'm optimistic that it will continue to occasion more conversations about the role of racism, redlining, and the state in inequalities of wealth in American cities. This presentation will provide an opportunity to critically reflect upon these materials and gauge the success and failures of this particular digital humanities project and perhaps the digital humanities more generally in informing socially and politically important public conversations. This presentation will also reflect upon the pros and cons of interpretive framing in digital humanities projects aimed at the public.

Mapping the Federal Writers Project

Lauren Tilton and Taylor Arnold

“Mapping the Federal Writers Project” will explore the role and implementation of deep mapping and spatial analysis in interpreting and understanding documentary expression in 1930s America. As Bodenhamer argues, deep maps are “visual, time-based genuinely multimedia and multilayered” (Bodenhemer, 11). These maps allow for nuanced spatial analysis in the service of new humanities questions and arguments. We will focus on the application of these concepts in a new extension of Photogrammar (photogrammar.yale.edu), a digital and public humanities project focused on print and visual culture in 1930s America.

Photogrammar (photogrammar.yale.edu) uses methods from the digital humanities and digital resources to further contextualize and open new avenues of research into the federal project and documentary record of the era. In its current version, Photogrammar maps 170,000 photos from the Great Depression and World War II that comprise the United States Farm Security Administration and Office of War Information (FSA-OWI) photographic archive. Importantly, the collection includes some of the most prominent documentary photographers of the 20th century including Dorothea Lange and Walker Evans. Users can explore the collection through interactive maps through the use of spatial analysis; search by photo captions, photographer and time through text analysis; and browse by color and the faces depicted in the photographs through the use of image analysis. This new stage - funded by the American Council of Learned Societies- involves adding a new layer to Photogrammar - the Federal Writer’s Project (FWP), which funded writers to capture and describe the complexities of American life during the Great Depression (Couch, Hirsch, Mangione, Penkower, Stewart). Dozens of writers were sent to document through words the impact of the great depression on people's lives across the country. Prominent literary scholars such as Nelson Algren, known for The Man with the Golden Arm , and Ralph Ellison, known for Invisible Man. In the process, they asked people to provide their life histories pioneering the practice of oral history, a critical methodology in the field of history and in the humanities more broadly.

Using deep mapping to expand our understanding of 1930s America, Photogrammar is creating links across archives in order to place the FSA-OWI in the larger federal effort to document America during the Great Depression. Merging collections from the University of North Carolina - Chapel Hill Libraries and the Library of Congress, the FWP includes over 4,000 life histories. Interviews are being plotted on a new geographical layer allowing search by space and time. For example, a user will be able to follow an interviewer as they move across a state and the country to collect oral histories in the same way they can now follow documentary photographs like Dorothea Lange and Walker Evans. Users will be able to search the new FWP layer independently or along with the geographical layer of FSA-OWI photographs and photographers. As a result, they will be able to compare the oral histories to the photographs taken in the same area allowing user to compare and contrast the documentary record created and funded by the federal government. As well, the new and cleaned transcripts created over this year are allowing for refined search functionality including faceted browsing and full text search. We are also experimenting with the role Natural Language Processing techniques such as Named-Entity Recognition to create new ways to browse the collection (Finkel and Manning 2005). In all, users will be able to explore the FWP and FSA-OWI spatially, temporally and through faceted searching allowing the public to explore the broader documentary record of the era relationally through deep mapping.

The second half of the paper will focus on methodology. We will start by discussing the potential benefits and potential difficulties of cross-institution collaboration in the cleaning and processing of data. In our experience, working with institutionally and spatially separated groups requires careful planning, but this extra up-front work improves both the general workflow and final products. We will touch on what scholarly and which technical questions guided our creation of a database schema for inputting metadata from the Federal Writer's Project. We take into consideration theoretical work regarding the creation of "smart data", best practices regarding TEI markup (Schöch, TEI Initiative on Libraries), and principles for creating normalized database tables (Codd 1971). The discussion will culminate in showing how these carefully curated data sources are made interactive and public on our website. The geographic data are plotted using custom layers created in CARTO (formerly CartoDB), giving a great deal of interactivity out of the box. Specifically, we will extrapolate on how we designed the interactivity to enhance the other data collections on the Photogrammar website, to make new arguments and pose new questions about documentary expression in 1930s America, to realize the principles of deep mapping and to engage with various publics.

Mapping Silicon Valley

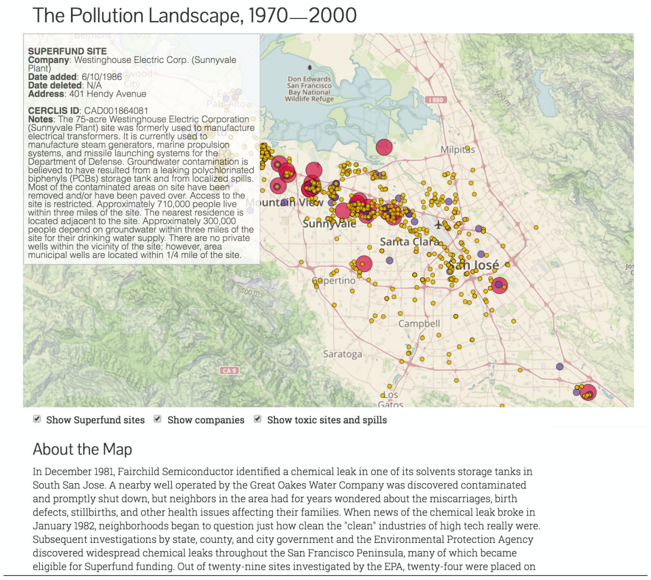
Jason Heppler

“Mapping Silicon Valley” explores the role of spatial history in the urban environment of post-World War II Santa Clara Valley. Silicon Valley is the product of competing landscapes. The geographer D. W. Meinig refers to landscapes as “a naïve acceptance of the intricate intermingling of physical, biological, and cultural features which any glance around us displays" (Meinig, 1979). Wildlife refuges, fenced military installations, city and neighborhood districts, and polluted sites all hold definitions on the land. Historian Richard White has referred to this as "hybrid landscapes," where cultural ideologies clash over conflicting uses of natural resources. The hybrid landscape is neither purely wild nor purely built, but instead a construction of natural and cultural systems that shape and create place (White, 2004). People define places by embedding ideas on the landscape. In cities, urban planners lay down grids of roads, zones, and regulations that divide cities along labor, leisure, and consumption, thus imbuing certain places with particular meaning. Landscapes, as Meinig notes, are “a great exhibit of consequences," and are “symbolic, as expressions of cultural values, social behavior, and individual actions worked upon particular localities over a span of time" (Meinig, 1979).

By viewing Silicon Valley through the lens of landscapes and space, I argue for the importance of place in shaping a suburban vision of what urban historian Margaret O'Mara has called high-tech urbanism. Silicon Valley has come to represent the future of post-industrial economic development. Places as varied as Atlanta, Georgia; Philadelphia, Pennsylvania; Cleveland, Ohio; Omaha, Nebraska; Bangalore, India; Mission Hills in the Guandong Province of China; and Shenzhen, China, have looked to Silicon Valley as a model for economic and urban revitalization through high-tech economic development. Indeed, high tech is often drenched in green--from high-tech office campuses to "smart cities" that promise to transform work, leisure, transportation, and urban space into a more sustainable future.

The work of this high-tech landscape has been decades in the making and has come with high environmental costs, despite the promise of clean and green cities. Silicon Valley epitomized the trend of conflating a lack of smokestacks as a proxy for sustainable industrial development. High-tech landscapes centered around industrial research and scientific industry promised growth without pollution, but that promise was an impossible standard.

"Mapping Silicon Valley" is a broad discussion of three map-centric projects that have moved through different stages. The first set of maps were data driven thematic maps, produced largely during the course of my dissertation research. These maps were created largely out of a desire to understand the transforming landscape in Silicon Valley, from city growth and conflicts over urban space to the widespread presence of pollution and neighborhoods most threatened by toxic chemicals. The first section of this paper will reflect on the methodological underpinnings of these maps and their application to environmental humanities, while also discussing some of the potential shortcomings and enhancements that would make these maps more useful for historical research.



The Pollution Landscape, 1970—2000

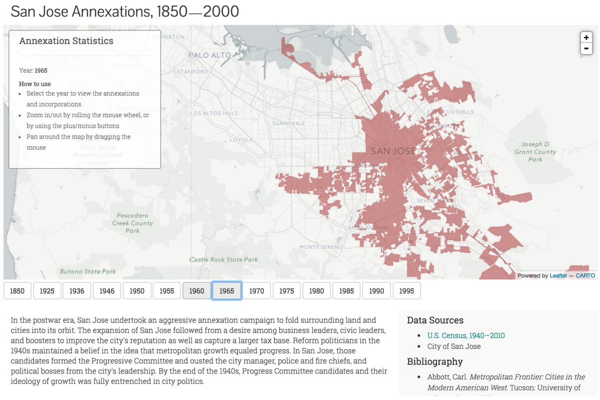
SUPERFUND SITE
Company: Westinghouse Electric Corp. (Sunnyvale Plant)
Date added: 6/10/1986
Date deleted: N/A
Address: 401 Hendy Avenue

CERCLIS ID: CAD001864081
Notes: The 75-acre Westinghouse Electric Corporation (Sunnyvale Plant) site was formerly used to manufacture electrical transformers. It is currently used to manufacture steam generators, marine propulsion systems, and missile launching systems for the Department of Defense. Groundwater contamination is believed to have resulted from a leaking polychlorinated biphenyls (PCBs) storage tank and from localized spills. Most of the contaminated areas on site have been removed and/or have been paved over. Access to the site is restricted. Approximately 710,000 people live within three miles of the site. The nearest residence is located adjacent to the site. Approximately 300,000 people depend on groundwater within three miles of the site for their drinking water supply. There are no private wells within the vicinity of the site; however, area municipal wells are located within 1/4 mile of the site.

☑ Show Superfund sites ☑ Show companies ☑ Show toxic sites and spills

About the Map

In December 1981, Fairchild Semiconductor identified a chemical leak in one of its solvents storage tanks in South San Jose. A nearby well operated by the Great Oakes Water Company was discovered contaminated and promptly shut down, but neighbors in the area had for years wondered about the miscarriages, birth defects, stillbirths, and other health issues affecting their families. When news of the chemical leak broke in January 1982, neighborhoods began to question just how clean the "clean" industries of high tech really were. Subsequent investigations by state, county, and city government and the Environmental Protection Agency discovered widespread chemical leaks throughout the San Francisco Peninsula, many of which became eligible for Superfund funding. Out of twenty-nine sites investigated by the EPA, twenty-four were placed on



San Jose Annexations, 1850—2000

Annexation Statistics

Year: **1965**

How to use

- Select the year to view the annexations and incorporations
- Zoom in/out by rolling the mouse wheel, or by using the plus/minus buttons
- Pan around the map by dragging the mouse

In the postwar era, San Jose undertook an aggressive annexation campaign to fold surrounding land and cities into its orbit. The expansion of San Jose followed from a desire among business leaders, civic leaders, and boosters to improve the city's reputation as well as capture a larger tax base. Reform politicians in the 1940s maintained a belief in the idea that metropolitan growth equaled progress. In San Jose, those candidates formed the Progressive Committee and ousted the city manager, police and fire chiefs, and political bosses from the city's leadership. By the end of the 1940s, Progress Committee candidates and their ideology of growth was fully entrenched in city politics.

Bibliography

- Abbott, Carl. *Metropolitan Frontier: Cities in the Modern American West.* Tucson: University of

The second mapping project is oriented around digital public history. Called Silicon Valley Historical and built on the Curatescape platform, the project seeks to collect archival material and narrate the importance of specific places to the Valley's history. Contributions to Silicon Valley Historical are not solely driven by scholarly contributions, but also rely on contributions by students and volunteers in close association with area universities, colleges, historical associations, and historical societies. The material contained in Silicon Valley Historical is meant, in part, to step away from the business-centric stories so often associated with Silicon Valley and consider more fully the urban spaces that were affected by the growth of this high-tech region. Still in its early stages of planning, this section will discuss the challenge of working with community partners and developing a sustainable and scalable digital history project that seeks to serve both the community it studies as well as students and scholars who will find the project useful.

The final mapping project, still under planning and a partnership with the Stanford Spatial History Project, is tentatively titled From Orchards to Suburbs: Changing Landscapes in Silicon Valley and will represent the most technological and research heavy aspects of the project. As I investigate the politics surrounding the creation of place, this project will allow for the spatial exploration of zoning laws, general plans, government reports, and city council meeting minutes. The current design envisages the ability to navigate through a map and, depending on the viewport, presenting a list of primary sources available for reading about particular places in Silicon Valley. These will be accompanied by some computational and statistical tools for doing text analysis to uncover more about the kinds of conversations happening about particular places in the city and how they are being thought about.

Collectively, "Mapping Silicon Valley" will critically reflect on these projects and their evolution as research and public history projects. The paper will further delve into the opportunities for deep mapping and interactivity for exploring the changing landscapes of Silicon Valley.

University of Nebraska-Lincoln, United States of America

This proposed panel will use a phenomenological perspective as well as a production-oriented approach to the work/research on which we are collaborating (‘Schrifttanz zwei’). Although digital technologies support this multi-disciplinary project that combines archival research, dance choreography, music composition, animation creation, and video projection with a goal of performance production, this panel will present our collaborative process and how we access and move through the digital and analog spaces in which we each work. The hope is that through this discussion (and performance event) attendees (and we as collaborators) will come to better understand the place of the Arts (Humanities writ large) in the Digital world.

The idea for Schrifftanz zwei began at the DH2016 conference where long-time DHers Steve Ramsay and Brian Pytlik Zillig presented their work with music and animation: ‘Picture to Score: Driving Vector Animations with Music in the XML Ecosystem’. Well known for their work within the Digital Humanities arena, their presentation demonstrated that the two had crossed boundaries into the nonverbal world of the arts. Two attendees who listened to their talk quickly became interested in collaborating. But these two, Rommie Stalnaker and research colleague Susan Wiesner, hail from the other side of the fence: they are Performing Artists who choreograph, perform, and conduct DH research using Dance. Sharing their desire to work with Ramsay and Pytlik Zillig, the four became inspired by the possibilities and began what has become an exciting collaboration challenged by three time zones, 3000 miles, and four personal processes for re-imagining a dance score created in 1927 by Irmgard Bartenieff, founder of the Laban/Bartenieff Institute for Movement Studies.

The original document from which we re-imagine the dance was discovered during the processing of an archival collection at the University of Maryland Special Collections in the Performing Arts. Bartenieff, a dancer and student of Rudolf Laban, brought Laban's theories about movement and his notation system to the USA in 1936 when she emigrated from Germany. Bartenieff began composing dances while studying with Laban in 1926-1929, yet she wasn't yet an expert in Schrifttanz, Laban's initial label for his notation system (Kinetography Laban, or Labanotation). Instead, she used her own hybrid system consisting of symbols, colour, and text to describe the dance movement and space. Better known for her work with Somatics, Laban's Effort/Shape theories, Motif writing, and Labanotation, the discovery of 4 choreographic works within Bartenieff's notebooks dated 1927-28 generated a desire to see them off the page (excerpt included here, Figure 1).

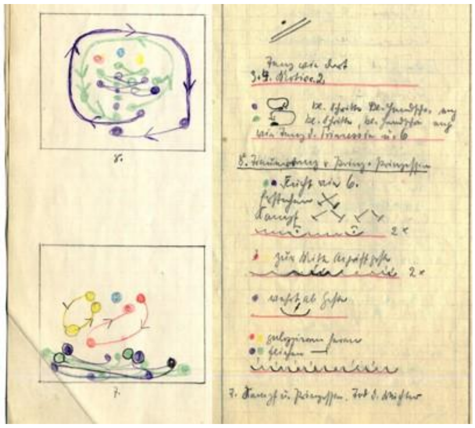

Figure 1: Excerpt from one of Bartenieff's notebooks

Because there are few particulars surrounding the work (who, what, when, where), we recognized that it is impossible to recreate it as it was without additional sources of information. Thus we decided to proceed with a re-imagining of the score to challenge our disciplinary approaches while giving voice to our individual creativity. For example, although the score is not written using Motif writing, nor Labanotation as we know them today, Bartenieff did call upon her knowledge of Laban Movement Analysis (LMA) by including a few elements in her textual descriptions. As the choreographers and dancers are all either CMAs or students of LMA we were able to understand those concepts integral to LMA. Also, we were able to support the movement choices made during the re-imagining by referring to Rudolf Laban's theory (from his 1926 *Choregraphie*), Bartenieff's personal movement style (referred to in archival papers as "Light"), and an analysis of the movement vocabularies used by German choreographers working in the 1920s.

Another factor in this project is the acknowledgement that researchers who attempt to use Laban theory and Notation in Computer Recognition and HCI continue to encounter what are often perceived as insurmountable issues. With the inclusion of LMA into Schrifttanz zwei (analyzing the performative product) we will not only use Bartenieff's work to inspire, but also to move closer to solving some of the issues faced by researchers using movement-based data. Thus, previous work on the ARTeFACT project (Wiesner and Stalnaker), which has long strived toward the use of Motif writing and LMA to enable automated tagging and retrieval of movement-based data, supports Schrifttanz zwei as yet another piece of the puzzle toward these goals.

So, too, does Schrifttanz zwei enable all team members to acknowledge our creative practices within a research framework. We each must interpret the verbal instructions and visualizations on some level through sound, visuals, and physical movement, i.e. the choreographic process must find a mutuality with Ramsay's musical composition and Brian's SVG videos inspired by Bartenieff's choreographic notes, graphics, and descriptions. Ramsay and Pytlik Zillig's recent artistic work uses Indigo, a program developed by Brian L. Pytlik Zillig for performing command-line stop-motion animation using Scalable Vector Graphics (SVG). Indigo produces thirty SVG files for each second of film, rasterizes them into JPEG images, and assembles them into H.264 high-definition video. Indigo animations can be quite simple or very complex. They may include text, shapes, colors, paths, layers, masks, and patterns. Indigo may be used to construct elaborate jointed characters that walk, talk, dance, or fly. Animations are modeled in XSLT and SVG, and can be programmatically synchronized with pre-existing audio using MusicXML metadata.

Schrifttanz zwei is admittedly an interdisciplinary artistic collaboration, but we would argue that the production of a work of art does not preclude the use of the digital; and indeed, Schrifttanz zwei includes born-digital elements (music and animation) intertwined with the born-human components and written/archived texts. Also, this collaboration is possible because of the prior work of the collaborators as it reflects the early phases of ARTeFACT and Ramsay and Pytlik Zillig's work with animation produced from digitized musical scores (Indigo). The proposed panel will address our collective and individual experiences in our art forms, as well as experiences using text and movement-based approaches in our DH research. Further this project is intended to create a Whole, where all voices and art forms share equal value with the supporting technologies, without privileging any one element. To accomplish this, we must negotiate within Digital Humanities AND the Arts. In fact, through this collaboration we have been made even more aware of the conversations surrounding definitions of the Digital Humanities, a topic we keep returning to during our collaboration. To wit: what is the place of the Arts in the Digital Humanities and what is required of a project to be aligned with the Digital Humanities? As DH artists as well as producers and users of digital technologies (e.g. Indigo, ARTeFACT, IDMove, etc.), we hope this panel/performance will provoke discussion and perhaps inspire others to find ways to access other 'outlier' disciplines through collaborative activities. Finally, as this collaboration constantly reminds us: "As technology and machines consume more and more of life, perhaps theater [read: dance] can help us remember what it means to act like a human." (Moore, 2016)

As an added component -- although the non-verbal is not included as an official ADHO language -- we plan to consider it as a communication method by allowing attendees to access their embodied knowledge through a brief non-verbal experience during the panel, including a request that some questions be asked and answered non-verbally.

Copyright is controversial and murky. By any name, it refers to rights connected to original works. In some countries, emphasis is on the rights of authors or distributors of a work; in others, public good is given prominence. In most places it's a combination of the two. Significant commercial and personal interests are involved, and the advent of the internet has redefined distribution; and so copyright laws are constantly changing. Although the notion of intellectual property exists in almost all countries its significance and actual implementation varies as does the degree to which the counter balancing rights of access to information are implemented and supported.

In digital humanities, copyright is implicated in multiple ways. As with all scholarship, book and article publishing is fraught with rights transfers embedded in publishing contracts, and subsequent publisher practices that often impede scholarly progress. Other copyright issues are unique to DH. Who holds copyright to what part of a collaborative, web-based project? What is the difference, and what are the intersections, between having, protecting, and exercising legal rights on one hand, and being given proper credit on the other?

We propose a DH2017 panel to discuss these issues, with an eye toward helping DH practitioners make better informed decisions regarding the new knowledge they create. More importantly, though, we aim to spur a community conversation about copyright as an area in which digital humanists have agency as knowledge producers, not just as consumers. The rapid worldwide expansion of digital humanities work demands that we begin to deal with the complex tangle of rights around digital humanities knowledge production before others do it for us.

This conversation has not yet happened at the DH conference or in the field at large in a robust way. Copyright is mentioned usually as an issue around using third-party materials, an obstacle or a limitation for a particular project (Neuman, Greent, Unsworth 1997; Evenson 1999; Lord 1999; Ben-Porat, Reich, Behrendt 2002). We were unable to locate conference abstracts that addressed copyright and intellectual property issues for the new knowledge produced. Workshop-type events on DH and copyright tend also to take a more applied approach, on how third-party copyright affects the project. Two related conversations are taking place, though. One is about labor in academe at large and in DH in particular (Keralis, Burgess and Hamming, Anderson et al, Flanders); the other is about access to knowledge as a social justice issue—what access to scholarship means in terms of power distribution, perpetuating systemic inequalities in academe and outside it (Risam et al, Chenier, Faull et al). We think that our panel will contribute to this conversation. Considering questions of labor from the perspective of rights to knowledge produced potentially clarifies, and makes more expansive, our collective notion of where labor exists in a digital humanities project. And, thinking of the knowledge we produce in terms of rights we possess to it highlights our agency as individual contributors. This enables us to consider whether our individual and collective practice around author rights promotes or impedes our work's overall contribution to society.

We envision this panel beginning with a 10-12 minute presentation from each panelist on the topics described below, followed by a discussion with the audience.

Isabel Galina Russell will speak on the long tradition of Open Access publishing in Latin America and discuss how this may have impacted the way in which DH resources are produced, disseminated and published in this region. She will draw on examples of DH projects in the region and analyse the copyright situation, as well as present the results of conversations with DH creators and their attitudes and experiences with copyright in relation to their work.

Alex Gil will address the intersection between shadow libraries, digital humanities, vendor databases and digital libraries. Departing from the research work of the Piracy Lab and the Group for Experimental Methods in the Humanities at Columbia University, Gil will argue that our burgeoning global, hybrid republic of letters is being shaped in specific ways by the relationship of specific sectors of society to intellectual property. In a sense, Gil argues, architectures of humanistic knowledge are being produced by these different sectors, where the end product may resemble each other, but in large part due to the work of intellectual property laws, the labor conditions and social impact are quite different. The talk will conclude with a series of proposals for future humanistic research in the burgeoning area of what Alan Liu calls "critical infrastructure studies."

Padmini Ray Murray will address how the global hegemonies of knowledge production, ownership and circulation are challenged by creation and consumption practices in India, as embodied by the landmark ruling of the Delhi High Court in 2016, which dismissed suits filed by three international publishers who alleged that the circulation of photocopied material was an infringement of copyright. This will contextualise Ray Murray's consequent discussion of how both academic publishing and conventions of copyright are largely colonial legacies, and how this case marks a significant moment in the decolonisation of the Indian university and intellectual life. Ray Murray will demonstrate how practices in Indian language publishing might exemplify alternatives to dominant regimes, as well as how digital spaces and practices can and are already fostering an emergent model of humanities scholarship different than that found in the global North.

Vika Zafrin will give a brief overview of the current state of copyright in the United States as it relates to academic work from both the consumer/reader/user and the creator/author points of view. She will touch on some struggles academic libraries face in the current scholarly publishing climate, and describe strategies some institutions have adopted to improve the situation, including open access policies and an access-oriented approach to stewardship of digital (or digitized) scholarly materials given to libraries for archival and preservation. Zafrin will compare the institution- and funding-agency-level approaches to open access generally taken in the U.S. to those seen in some European countries (and in Europe as a whole via the Europeana project), highlighting differences and comparing their effectiveness while taking account what is possible in the respective political and legislative climates. She will briefly discuss some representative collaborations between U.S. researchers and colleagues worldwide, and their treatment of rights issues. Finally, she will make some suggestions for resources DH practitioners can use to make decisions about rights claims and attribution in their projects.

Smart Data Approaches to Exploring Independent Datasets across Disciplines, Media, and Perspectives for Research in the Humanities

Marcia Lei Zeng
mzeng@kent.edu
Kent State University, United States of America

James Lee
james.jlee@uc.edu
University of Cincinnati, United States of America

Research in the humanities has embraced the data-driven environment where advanced digital technologies have created the possibility of novel and hybrid methodologies. While the world is amazed by the many "V"s of Big Data (volume, velocity, variety, variability, veracity), the "V"alue of such data relies on the ability to achieve big insights from such data at any scale, great or small (Kobielus 2016). Smart Data can be considered trusted, contextual, relevant, cognitive, predictive, and consumable. In humanities research, Smart Data emphasizes the organizing and integrating processes from unstructured data to structured and semi-structured data, to make the big data smarter (Kobielus 2016, Schöch 2013).

In this panel, the interdisciplinary research teams from two universities will share their research findings and products as well as their experiences of using smart data approaches. As is the case with many other projects, the teams have to face the inherent challenges of converting heritage materials that were not machine-processable into digital datasets. Furthermore, the teams (again, like many others) have used common applications of available digital technologies and tools, such as GIS mapping, text encoding, fact mining, database construction, and visualization. In addition, the projects have employed sophisticated computer logics, the Linked Data models, network theory, and temporal-spatial data analytics, among others. However, the unique value of these projects lies in the exploration of independent datasets across disciplines, media, and perspectives. Some of such datasets were built from unstructured data and media, while some other datasets have been existed isolated because the values are hidden in the silos. By drawing on many types of data simultaneously and interactively in an unprecedented manner, the research findings and established resources help reveal the unknown-unknowns and interpret significant values.

To begin the panel, Dr. Marcia Zeng (Professor of information science) and Dr. Hongshan Li (Professor of history) will report on the project "Digital Humanities Research with Smart Big Data — A Network Framework of Innovation History" using the case of the Liquid Crystal Institute (LCI) at Kent State University (KSU), the birthplace of liquid crystal displays. Through the work of its faculty and alumni, LCI has had a significant impact on the way the world sees things –on our smartphones, tablets, and computer screens (Bos, 2015). By nature, innovations and inventions demand collaboration across various kinds of networks. More and more collaborative efforts, instead of individual hero-inventors, resulted in the innovations in the last two centuries and, even more apparently, today. This project has focused on a community of scientists in one large institution instead of individual scientists. The project intended to use comprehensive data from cross disciplines and perspectives to discover meaningful patterns in the history of innovation. The presentation will discuss various research methodologies applied to different types of data used by a research team consisting of more than 10 faculty members and research assistants from the disciplines of information science, history, geography, physics, visual communication design, and mass communication. The presenters will share the integrated research findings regarding the sophisticated relationships and networks of contributed factors and impacts over LCI's 50-year history that complement traditional study of the history of science and technology. The presentation also aims to share our lessons and roadmaps of taking smart data approaches with the intention of helping more researchers to overcome the challenges in researching the innovation history in the digital age.

The second presentation will be given by Dr. James Lee and Arlene Johnson, co-directors of the Digital Scholarship Center at the University of Cincinnati (UC), along with members of their team. They will describe the team's research entitled "Linked Reading," which uses sophisticated machine logics to allow researchers to directly query, analyze, and visualize or sonify data from multiple independent datasets, including the University of Cincinnati's Elliston Poetry Archive. Since 2010, UC Libraries and the Department of English & Comparative Literature have collaborated on The Elliston Project, an audio archive of over 700 recordings of poetry or poetry-related content. The recordings span seven decades and include over 450 poets, including Wendell Berry, Robert Frost, Allen Ginsberg, Louise Glück and a host of others. Alan Liu, a pioneer of digital humanities in literary studies, considers the Elliston project to be a "world-class poetry audio archive," which has the potential to "alter the dominant understandings of a 'digital archive' developed for textual materials." Linked Reading allows one to examine scholarly questions on the question of poetry from multiple angles at once by pivoting laterally between multiple audio and text datasets. A unique opportunity for researchers and educators lies in constellations of micro and nano datasets that have been inadequately studied or even ignored. This approach, gathering smaller datasets of creative materials into a linked network, allows the team to leverage the local strengths in the humanities and creative arts (represented in stellar fashion by Elliston) to facilitate heretofore impossible research projects. Consider, for instance, poetic tone. It's a basic tenet of poetry instruction that the poem on the page is but a score to be performed; and yet, poetry scholarship is in virtually every instance a study of the printed poem. The project illustrates a potential of reshaping this well-studied topic by 'reading' the sonic features of poetic tone in massive numbers of poetry recordings across many linked smaller archives. As such, the aims of this research are: 1, to transform the techniques of linked data into an analytical and interpretive method, and 2, to adapt well-establish machine learning techniques honed on text datasets for the analysis of large archives of born-audio creative works.

Long Papers

Digital Humanities as Critical University Studies

Matt Applegate
mapplega@gmail.com
Molloy College, United States of America

In her 2011 article, "All the Digital Humanists are White, All the Nerds are Men, but Some of Us Are Brave," Moya Z. Bailey unearths a radical, unrealized potential in the Digital Humanities that few have made explicit since its articulation: a practice of the digital humanities that is also a practice of critical university studies. I cite Bailey here in full:

> In blog posts, Miriam Posner and Bethany Nowviskie have both addressed the structures that impede women from connecting to digital humanities. The increase of women in higher level positions within universities have led to changes in the infrastructure, with child care and nursing nests cropping up on campuses across the country. Similarly, people of color have been engaging in critical university studies long before the 1990s when the field is said to have emerged. By demanding space as students and faculty, in addition to advocating for rights as the laborers that built and maintain these institutions, people of color have organized through concerted effort to bring about changes in institutional culture and structure.

The question of diversity and inclusion that informs this intervention is intimately linked to institutional austerity and the precaritization of intellectual labor. Post-2008, the economic pillaging of the university is undeniable. It is also undeniable that the digital humanities emerged as a contemporary force for disciplinary transformation during this precise economic shift. Matthew K. Gold states this matter of factly in his introduction to the 2012 *Debates in the Digital Humanities* anthology, "The Digital Humanities Moment": "At a time when many academic institutions are facing austerity budgets, department closings, and staffing shortages, the digital humanities experienced a banner year that saw cluster hires at multiple universities, the establishment of new digital humanities centers and initiatives across the globe, and multimillion-dollar grants distributed by federal agencies and charitable foundations."

The university's loss coextensive with DH's boon requires further interrogation. This paper builds on Bailey and Gold's work by directly linking concerns in DH for diversity and inclusion to economic disparities in the university via critical university studies. I do so not to condemn DH for its rise, but to continue to unearth its radical potential. While the literature in critical university studies is broad, I connect DH to two critical university approaches in particular: decolonial feminism and Autonomist Marxism. Both approaches augment current debates in DH as they forefront questions of inclusion, diversity, and economic variance, but also provide more pointedly political approaches to pedagogy and tool-use.

In her 2003 book, *Feminism Without Borders*, Chandra Talapade Mohanty claims that "the moment we tie university-based research to economic development–and describe this research as fundamentally drive by market forces–it becomes possible to locate the university as an important player in capitalist rule" (173). This claim is couched in a decolonial method committed to developing "the urgent political necessity of forming strategic coalitions across class, race, and national boundaries," but it is also motivated by a commitment to feminist struggle (9). The university is a site of decolonial feminist struggle in particular because it is a "contradictory place where knowledges are colonized but also contested [...] It is one of the few remaining spaces in a rapidly privatized world that offers some semblance of a public arena for dialogue, engagement, and visioning of democracy and justice" (170). What follows is therefore a simple claim, but one that is difficult to reconcile in a contemporary context, especially as it might apply to DH: "Feminist literacy necessitates learning to see (and theorize) differently–to identify and challenge the politics of knowledge that naturalizes global capitalism and business-as-usual in North American higher education" (171).

It does not take a careful reader to detect a radical undercurrent to Mohanty's interest in feminist literacy, nor should it be a surprise that those disproportionately affected by institutional inequity might rely on a radical political logic with which to situate their intellectual labor. Perhaps the strongest emergent DH interest in which Mohanty's work carries the most methodological weight, however, is found in Roopika Risam's essay, "Navigating the Global Digital Humanities: Insights from Black Feminism." There, Risam argues that

> As the field of digital humanities has grown in size and scope, the question of how to navigate a scholarly community that is diverse in geography, language, and participant demographics has become pressing. An increasing number of initiatives have sought to address these concerns, both in scholarship–as in work on postcolonial digital humanities or #transformDH–and through new organizational structures like the ALliance of Digital Humanities Organizations (ADHO) Multi-Lingualism and Multi-Culturalism Committee and Global Outlook::Digital Humanities (GO::DH), a special interest group of ADHO.

We see similar issues at work in #transformDH and feministDH more broadly. However, Alan Liu's recent claim to a critical infrastructure studies augments these concerns. Liu summarizes his interest in critical infrastructure studies as a “call for digital humanities research and development informed by, and able to influence, the way scholarship, teaching, administration, support services, labor practices, and even development and investment strategies in higher education intersect with society.” The rhetorical shift from “critical university” to “critical infrastructure” is interesting here. Where Liu goes so far to say that most, *if not the whole of our lives*, are organized through institutional mechanisms formative of a “social-cum-technological milieu,” “the word ‘infrastructure’ give[s] us the same kind of general purchase on social complexity that Stuart Hall, Raymond Williams, and others sought when they reached for their all-purpose word, ‘culture.’” Paired with Risam’s work above, Liu draws us to closer to a critique that would mirror Mohanty’s.

At the same time, Mohanty’s decolonial approach dialogues with Autonomist Marxist approaches to the same problem. Writing of their work with CAFA (Committee for Academic Freedom in Africa), George Caffentzis and Silvia Federici comment on institutional formations like those that Mohanty invokes, but also those that are already operative in DH: global initiatives organized around a common goal. Where Caffentzis and Federici depart from the question of DH infrastructure is certainly a question of technological focus, but also it is also a political one. “As was the factory,” Caffentzis and Federici write, “so now is the university” (125). The import of this claim comments on our institutional alliances, as well as our collective understanding of what educational institutions are for. Thinkers of critical university studies define the university this way because it maximizes the forms of solidarity that are available to us in the face of sovereign institutional control.

For both DH and the Autonomist approach, solidarity is most prominently featured in tool-use and production. Following Caffentzis and Federici, Gigi Roggero mobilizes critical university studies toward a reinvention of the tool. In his article, “Notes on Framing and Reinventing Co-research,” he argues that “tools of inquiry have to be reinvented at the level of the general intellect’s networks, going beyond the division between the virtual and the real,” in order to maximize living labor’s break with capital, opening up a space for co-research to form a “material base for revolution” (520-521). DH’s reinvention of the library, the archive, and the application of technology to humanistic inquiry more generally have never been more apt. At the same time, a strong dialogue with Liu and Risam’s work, stemming from Bailey’s claim to DH as critical university studies, is brought to the fore in Roggero’s work.

This paper concludes by theorizing what forms of alliance/solidarity might be drawn between DH’s transformative work at the level of infrastructure with critical university studies’ political work at the level of the institution. I argue that the university is not a freestanding institution; it is embedded within processes of real subsumption that span the whole of contemporary life. Concerns for diversity and inclusion are contoured by this fact, and the transformative power of tool-use extant in DH praxis resist it.

Machine Vision algorithms on cadaster plans

Sofia Ares Oliveira

École Polytechnique Fédérale de Lausanne, Switzerland

Introduction

Cadaster plans are cornerstones for reconstructing dense representations of the history of the city (di Lenardo and Kaplan, 2015). They provide information about the city urban shape, enabling to reconstruct footprints of most important urban components (buildings, streets, canals, bridges) as well as information about the urban population and city functions (census information, property, rent prices, etc.) (Noizet et al, 2013). Cadaster plans are usually the results of coordinated campaigns with standardized methods of measurement and representation. This means that large sets of documents follow the same representation conventions. This regularity opens the possibly of efficient automated process for analyzing them and possibly transforming the information they contain in geo-referenced databases that can be used as part of historical geographical information systems (Gregory et al, 2001).

However, as some of these handwritten documents are more than 200 years old, the establishment of a processing pipeline for interpreting them remains extremely challenging. This may explain why, to our knowledge, no such system exists in the literature. This article reports our effort in this domain, presenting the first implementation of a fully automated process capable of segmenting and interpreting Napoleonic Cadaster Maps of the Veneto Region dating from the beginning of the 19th century. Our system extracts the geometry of each of the drawn parcels, and classifies, reads and interprets the handwritten labels. We believe the general principle of technologies used in the process could be adapted to other cadastral funds, although this has not been tested in the present study.

Methodology

Literature on map processing includes works on many different types of maps, from roads to topographic maps, including hydrographic and cadastral maps. Most studies focus on particular problems and features and thus develop techniques that are highly map specific (Chiang et al, 2014).

Our work addresses the particular case of the Napoleonic cadaster of Venice dated 1808, but aims at developing a method highly adaptable to other cadasters with little extra effort.

We propose a system that segments the cadastral map, identifies and extract segmented objects such as parcels and identifiers and recognizes the extracted hand-written digits. A demo code with examples of the results can be found on Github.
The method is summarized in Fig. 1.

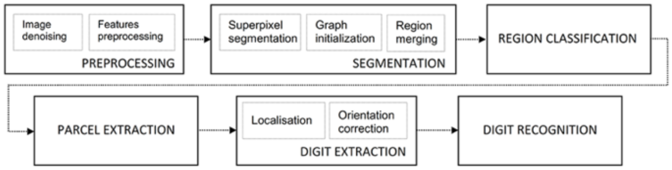

Figure 1: Overview of the system

Preprocessing

Usually, the processed images are ancient documents that have been digitized. To deal with the natural ageing of paper and eventual spots on the map without losing details, we use a non-local means de-noising method (Buades et al, 2005) to smooth the image.

Segmentation

We address the task of extracting the desired information from the document as a segmentation problem, which is a recurrent problem in image processing. A graph-based segmentation approach is adopted, which models the image as a weighted undirected graph. This allows to process the pixels or regions in the spatial domain of the image but also to use higher level information such as connections, similarities and dependencies between the elements.

Because a group of pixels sharing some similarities are more perceptually meaningful than a simple pixel, we use SLIC method (Achanta et al, 2012) to create superpixels. Superpixels are clusters of pixels that share similarities and spatial proximity and have the advantage of reducing the complexity of image processing tasks.

A graph is a mathematical structure composed of vertices and edges, representing a system of connections or interrelations among a set of objects. It is widely used to model relations, to study information systems or to organize data. In our case, the graph representing the image is initialized with superpixels as vertices. Its edges connect neighboring vertices (superpixels) and each edge has a weight which is a measure of the dissimilarity between neighboring elements. The distance (or dissimilarity) metric is based on color and edge/ridge features.

The oversegmentation of the image resulting from superpixel generation is then reduced by grouping superpixels into homogeneous regions and merging the corresponding graph vertices. Our approach uses global homogeneity, meaning that the method minimizes intragroup dissimilarity and maximizes intergroup dissimilarity. The 'dispersion' of edge weights (i.e standard deviation within a region) allows to spot high-weighted edges within a group and thus disconnect dissimilar vertices (i.e remove their edge) to end up with independent homogeneous regions.

Region Classification

The merged regions are classified into 3 classes: text, contour/delimitations and background (smooth textures such as parcels or streets) using a SVM classifier. The training data is composed of manually annotated samples of maps coming from the Napoleonic cadaster of Venice.

Parcel Extraction

The classification results allow the determination possible parcels candidates. A flood fill algorithm is applied, using a ridge detector to indicate boundaries. The chosen ridge detector was originally developed as a vessel enhancement filter (Frangi et al, 1998) and looks for multiscale second order local structures of the image that can be considered tubular. The obtained measure indicates how similar the structure is to a tube, and so it is able to detect ridges. Starting from one point in the regions labeled as background (seed point), the flood fill algorithm floods each zone, i.e parcels, streets, etc. and stops at the boundaries (output of the ridge detector).

Each parcel of the image is extracted as a polygonal shape and the polygon's corner points are stored in GeoJSON format. If the image file is geo-referenced and contains geographical information (a GTIFF file for instance), polygons are exported according to the spatial reference system provided. This allows a fast and easy integration of the shapes into a geographic information system (GIS) and geographic information on the parcels can easily be collected.

Digit Extraction

The parcel identifier is usually contained within the parcel. This observation and the extracted polygons' information can be used to correct misclassified text regions and improve identifier extraction. Elements labeled as text regions are localized, delimited by bounding boxes and grouped so that neighboring characters are extracted together. Again, information from polygons is used to determine whether neighboring digits belong to the same identifier or not (i.e whether neighboring digits are located in the same parcel/polygon). Boxes that do not correspond to identifiers or digits are removed according to specific criteria. Finally, the boxes containing the parcels' identifiers are extracted.

Since the digit recognition step requires horizontally oriented digits to output accurate prediction, the identifiers' boxes are rotated. A principal analysis component is applied to the binary image of the extracted numbers to determine the angle of the rotation.

Digit Recognition

The horizontally oriented numbers are separated into digits that are processed individually. A good digit segmentation is primordial since connected or overlapping digits lead to incorrect recognition. A Convolutional Neural Network (CNN) with two convolutional layers, two fully connected layers and a final softmax layer for multiclass classification is used to predict the identifiers. The CNN is trained on a mixed dataset composed of MNIST dataset (LeCun et al, 1998) and digit samples from Sommarioni register and has a performance of 99.1%. When predicting the numbers, the network outputs the inferred number with a confidence level indicating the reliability of the result.

Results

The proposed approach shows promising results in parcel extraction and identifier recognition. We performed the first 'proof-of-concept' evaluations on manually labeled data taken from different cadaster samples. The total number of annotated objects are shown in Table 1.

Most parcels and identifiers were correctly extracted (Table 2 & 3), which assured us of the feasibility of their automatic extraction. The precision can still be increased for example by using feedback from digit recognition results, i.e, the prediction and its confidence level permit the discarding regions where no reliable identifier has been recognized.

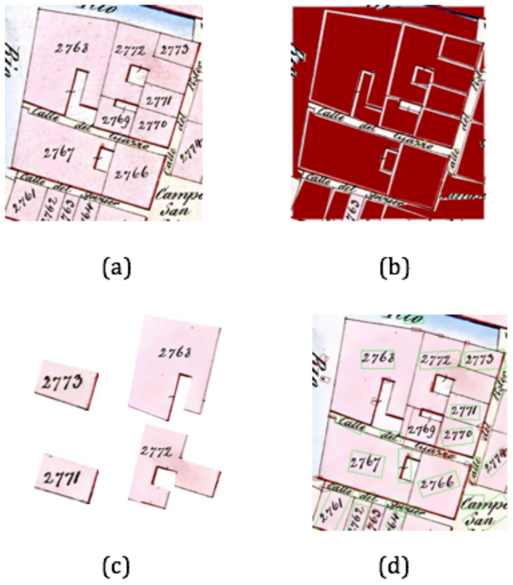

Figure 2: Sample of results: (a) original image, (b) polygon approximation of parcels, (c) extracted parcels and (d) identifier localization

Parcels with labels	810
All parcels (with and without labels)	1185
Parcels' numbers	736

Table 1: Count of ground-truth objects

	Labelled parcels			All parcels		
IoU	> 0.6	> 0.7	> 0.8	> 0.6	> 0.7	> 0.8
Recall	0.77	0.76	0.72	0.72	0.69	0.60
Precision	0.55	0.54	0.51	0.75	0.71	0.62
Ground-truth	810			1185		
Total extracted	1144					

Table 2: Results of parcel extraction with different Intersection over Union (IoU) thresholds

Concerning the digit recognition, only 10% of the identifiers had their digits correctly recognized. Since the models used have shown good performance on nicely detached digits, this is not the fault of the recognition algorithm itself but rather of the digit segmentation procedure. The current segmentation is the main hindrance to an efficient digit recognition, thus, further work should focus on a better number processing algorithm. Another alternative is to avoid the segmentation problem and use a recurrent neural network such as LTSM to process the number as a sequence.

Perspectives

Our work shows promising results for easing and accelerating cadaster processing, especially given our method's efficient parcel segmentation and digit identification. Moreover, the export of a parcel's geometry into GeoJSON format opens up further perspectives to efficiently geo-reference ancient maps. The system can be extended and integrated into a user interface to take better advantage from the results, for example by allowing the user to correct or add information about parcels and identifiers.

Inter	> 0.5	> 0.7	> 0.9
Recall	0.90	0.87	0.81
Precision	0.58	0.55	0.51
Ground-truth	736		
Total localized	1152		

Table 3: Results of parcels' number localization with different Intersection (overlapping percentage) thresholds.

	Correct number	Partial number			
		4 digits	3 digits	2 digits	1 digit
MNIST	58 (.09)	17 (.03)	105 (.16)	94 (.14)	165 (0.25)
MNIST-Sommarioni	66 (.10)	20 (.03)	90 (.14)	103 (.16)	163 (.26)
Total localized	637				

Table 4: Results of parcels' number recognition

The proposed method creates a bridge between previously seperate two data types: the raster object and the vector object. Currently, web-mapping tools consider vector objects as separate layers on the raster maps, and each object needs to be manually redesigned. The automatic vectorization process enables us to perform the visualization and annotation processes directly on the cartographic source without the prerequisite of complex skills. It should greatly facilitate large scale exploitation of such kinds of documents.

From Usability Testing and Text Analysis to User-Response Criticism

Introduction

Studies on user experience in the digital medium are often related to Human-Computer Interaction (HCI) and the construction of user models or the performance of usability tests in order to support design and evaluation of digital artefacts. User modelling research has mainly focused on the construction of “usable” and “useful” tools providing the users with “experiences fitting their specific background knowledge and objectives” (Fischer, 2001: 65). A variety of characteristics have been used to inform such models, from demographic information (age, gender, native language) or relevant experience (novice, advanced, expert), to interests, goals and plans (general interest categories, task-related objectives/sequences of actions) or contextual information (location, time, physical environment) (Sosnovsky and Dicheva, 2010: 33-34). Many of the approaches merge cognitive science and artificial intelligence (Webb et al., 2001; Biswas and Robinson, 2010; Mohamad and Kouroupetroglou, 2013), whilst usability testing, as a technique from user-centred design, often involves the iterative refinement of a prototype based on user’s feedback (Massanari, 2010). Usability studies also evaluate how a tool is actually used (Brown and Hocutt, 2015) exploring constructs such as ease of use and learnability. Other researches, from the fields of philosophy of technology or digital hermeneutics, go beyond the usefulness and usability aspects of the technology, trying to address questions related to the “human, social, cultural, ethical, and political implications of those technologies” (Fallman, 2007: 296) or to the “self-interpretation of human beings” (Capurro, 2010: 10) in the light of the code. Further directions of study propose a re-orientation of the HCI as “an aesthetic field” (Bertelsen and Pold, 2004: 23) or a cultural perspective on the “reflexive relationship between user and medium” as a “remediation” of the self (Bolter and Grusin, 2000: 230), considered as “humanistic HCI” (Bardzell and Bardzell, 2016).

This article tries to bridge the fields of HCI and Digital Humanities (DH), where HCI techniques are used to evaluate tools developed in DH projects and the results of this evaluation are analysed via DH methods, with the intention of potential development inspired by the literary theory of aesthetic response (Iser, 1980). The paper elaborates on previous work (Armaselu and Jones, 2016) and presents two case studies of usability tests conducted within the framework of interface and game design for digital historical editions and digital cultural heritage (Section 2). Section 3 describes the type of analysis applied to users’ responses, whereby we propose a typology of users and interpretation of users' experience, followed by conclusions and future work (Section 4).

Two case studies

The first case refers to the design and implementation of an XML-TEI-based platform (Transviewer) allowing the exploration of digital editions of historical documents through features for page-by-page navigation, side-by-side view (facsimile/transcription), free-text and named entities search. The usability tests inspired by previous studies (Nielsen, 2000; Jones and Weber, 2012) involved a user-group of 8 researchers in history, political science and linguistics, 4 males and 4 females, aged 25-64. They had to complete 17 tasks using the prototype and to fill-in a USE-based questionnaire (Lund, 2001). During the experiments, the users were asked to think-aloud and the audio and screen interactions were recorded. The common language was English, although none of the participants was a native speaker.

The second case uses data collected during three sessions of gameplay conducted as part of a requirements gathering and co-design process for Pilot 4 of the H2020 Crosscult project. Players were asked to play a board game and contribute reflections as they encountered historical objects pinned to various locations in the city (the Board was derived from a map of Luxembourg City). The first session contained 6 players (5 females, 1 male), the second 5 players (all female) and the third 5 players (4 males, 1 female). All players, aged 25 to 50, worked in a research environment, and none of the participants used English as his/her mother tongue. In the first session, players had 10 roles of the dice to score as many points as possible in successive rounds, the game was shortened so players had to score the most points and reach the end of a score board first.

Analysing user response

For both cases, the users' responses from the questionnaires were transcribed, when not already in electronic form. Partial transcription of the think-aloud audio recordings for the first case was performed (reflections on the experience, improvement suggestions, expressions of disorientation or frustration); the transcription of the second case video-audio recordings is not yet completed, therefore not included in the study. The transcribed snapshots were pre-processed (TXT, XML, R) according to the formats required by the analysis phase. Three types of software were used: Textexture – a tool for representing the text as a network (Paranyushkin, 2011); TXM – a statistical tool for corpus analysis; TheySay – a sentiment analysis package.

The first experiment with Textexture drew attention to noteworthy connections between different clusters of meaning related to users' experience as expressed in their responses. Figure 1 presents two examples: the first highlights how the notion of *trust* is related to the side-by-side view feature of the interface, as allowing the users to compare the transcription with the scanned original and make sure it can be trusted (left); the second illustrates the linking of the sub-networks for *player (reflection, discussion, exchange, opinion*), *place (location, malta, luxembourg)* and *story (card, map, point)*, which reveals the relations, at a conceptual level, between the significant features and interactions of the game.

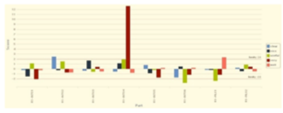
Figure 1.Textexture

TXM allowed contrasting the specificities scores (Lafon, 1980) corresponding to each user, in terms of overuse/deficit of words usage, as compared to the rest of the corpus. Table 1 shows the positive/negative specificities diagrams based on these measures for three groups of linguistic features. The scores above/under a banality threshold (+/-2.0) indicate highest specificity for responses from particular types of respondents, which allowed us to make hypotheses about a potential "typology" of users that can be described within both case studies.

Transviewer	Crosscult
Pronouns: *I, me, my, you*	Pronouns: *I, me, my, us, you, your*
	Conditionals, ability verbs and negation, uncertainty, difficulty: *can, know, n't, perhaps, should*	Conditionals, ability verbs and negation, uncertainty, difficulty: *can, complex, complexity, could, hard, might, should*
	Appreciative adjectives, superlatives: *clear, nice, useful, very, well*	Appreciative adjectives, superlatives: *good, interesting, nice, very*
	


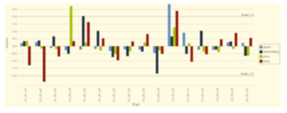


Table 1. TXM: User-response specificities

For instance, some users are characterised by an overuse of *I, my* or *you, your*, others by an alternation of them, which can create the impression of an "immersive", "distant" or "versatile" point of view: "Which *I* found strange. Yes, *I* have not yet used the big arrow buttons", "if *you* scroll, *you* have to scroll both" (Transviewer); "prefer to elaborate *my* own answer, without influence", "*I* think it triggers *your* own thinking process" (Crosscult). Similarly, the use of conditionals, negations and uncertainty adverbs are suggestive of a “sceptical” user, in contrast to experiences described with appreciative adjectives and superlatives indicative of an “enthusiastic” standpoint.

After exploring the results in TXM and identifying possible types of users, we analysed the responses via TheySay (Table 2).

	Transviewer (think aloud transcription)	**Crosscult** (questionnaire answers)
Immersed	Positive (**0.446**, 0.129, 0.425, 2163)	Positive (**0.533**, 0.082, 0.385, 253)
Sceptical	Positive (**0.451**, 0.163, 0.386, 2591)	Positive (**0.646**, 0.097, 0.256, 206)
Enthusiastic	Positive (**0.596**, 0.119, 0.286, 733)	Positive (**0.721**, 0.121, 0.158, 261)

Table 2.TheySay: overall and polarity scores (positive, neutral, negative, word count)

The results enabled us to explore differences in sentiment between the types of users. For example, the “enthusiastic” user from both experiments scores highly with respect to the measure of positive polarity, whilst the sceptical user scores are a bit lower but, interestingly enough, higher than the immersed user’s.

It was also observed that sometimes, irrespective the type of user, sentences with high score for humour may actually point to interaction-related aspects like disorientation, confusion, contrariety: “I was ... where was I?”, “I clicked on people but I don't know what happened” (scores 0.996 and 1, Transviewer); “I've never been in the flow because I can't focus on other gamers”, “didn't use any, but I don't think I would“ (scores 0.996 and 1, Crosscult).

Conclusion and future work

The paper describes two case studies in interface and game design dealing with the application of textual analysis to user-response via three systems, for visualisation of the text as a network (Textexture), corpus analysis (TXM), and sentiment analysis (TheySay). The research is still in progress and more experiments with new cases are expected to further support, test and validate the proposed user typologies and interpretation modalities, which might in the future inform humanistic interface design and approaching of user models. In addition, we expect to explore the theoretical matters, assuming that this kind of analysis, beyond its usability-oriented value, may inspire new paths of reflection on user’s self-projection in the digital space, at the intersection of digital hermeneutics, digital aesthetics, and the theory of literary response.

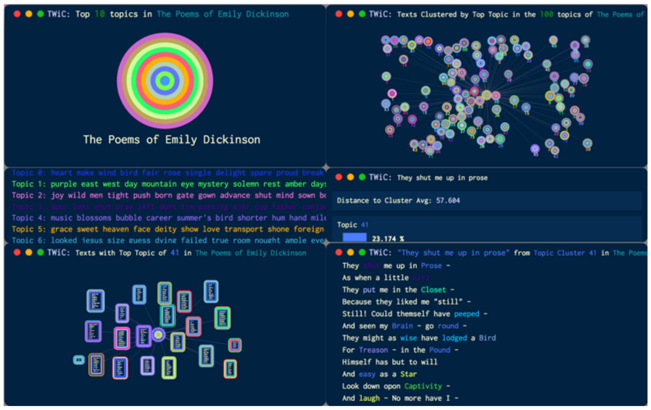
How to Close Read a Topic Model: TWiC Reads Emily Dickinson's Fascicles

Jonathan Armoza
jarmoza@gmail.com
New York University, United States of America

Abstract

The modeling of mass quantities of cultural objects has led the humanities in new and sometimes discomforting directions. Digital humanists have come to realize the stakes of such practices: emerging paths of scholarship that supplement but may also fundamentally alter the research methodologies and outputs of the humanities. Matthew Wilkens writes that the necessary "decay" of critical techniques that pay close attention to those objects is "a negative in itself only if we mistakenly equate literary and cultural analysis with their current working method" (Wilkens, 2012). One question that remains is if the quantitative working method of such large analyses is compatible with that "current working method" – in this case, the individual interpretation and critique of texts. In the years since Franco Moretti's "distant reading" paradigm became a commonplace, scholars have tested this useful if problematic dichotomy of "close" and "distant" reading. In 2013, for instance, Andrew Piper writes of the "topology" resultant from the dispersive techniques of programmatic text analysis. Setting the lexical components of texts in relation to one another, Piper envisions a tactic of "focalization" that can allow "readers" of such deconstructed texts to understand the relationships between those components (or characteristics) at multiple scales (Piper, 2013: 375). And yet there is always a "between" those multiple scales: "for every unity there can always be something between it and that which it succeeds" (381). Subsequently, there also exist important relationships between these scales of information that inform one another. When macroanalysis brings us to a point where we must return our close attention to our objects of study, we need be reminded of the model that brought us to that perspective in the first place. In focalizing, we are best served to maintain multiple foci. It is a natural tendency to want to confirm macroanalytic results by reading texts and by paying attention to the details of our mathematical models. But how might we do so while keeping the complex relationships of those models in mind?



TWiC: Top 10 topics in The Poems of Emily Dickinson

They shut me up in Prose –
As when a little Girl
They put me in the Closet –
Because they liked me "still" –
Still! Could themself have peeped –
And seen my Brain – go round –
They might as wise have lodged a Bird
For Treason – in the Pound –
Himself has but to will
And easy as a Star
Look down opon Captivity –
And laugh – No more have I –

Figure 1. “Topic Words in Context”: an in-browser tool for exploring the scales of data in a topic model

When digital humanists use topic models to explore large corpora of texts, they do so at an inherent disadvantage. Typically presented with flat files listing topics and topic weights, they are left to interpret these lists and figures separate from the texts that have just been modeled. Several significant tools have been developed to help scholars visually navigate the textual relationships in topic models. However, in the past few years I have been working on a practical, critical methodology for understanding topic models and the relations between their outputs and that "current working method" of the humanities: human-guided close and contextual reading. For this talk, I will take attendees on a visual exploration of a topic model of Emily Dickinson's poetry using a highly interactive and playful data visualization I developed for my Master's thesis, called "Topic Words in Context" – or "TWiC", for short. TWiC is a multi-paneled environment for web browsers that allows users to explore and juxtapose multiple scales of data in topic models of digital corpora. It uses shapes, colors, and cross-panel highlighting to get users of topic models from "big" data to "small" and back. Importantly, it also provides an alternate "publication" view that resituates modeled texts back into their original publication contexts (e.g. texts split for modeling purposes or texts within a collection). Recalling Piper's topological concepts, TWiC brings our focus simultaneously to these many textual and statistical relationships at play within a topic model. From corpus-wide topic distributions to texts to the topics themselves, each scale of the model when set against each other can reveal hierarchical qualities that enrich and move beyond the semantic/linguistic relationships frequently associated with the word lists of topic models. (Documentation and color screenshots of TWiC are available at in the README.md file at github.com/jarmoza/twic.) Of the many analytical techniques TWiC makes possible, I will demonstrate how we can produce expressive, critical comparisons between our close readings of texts and the smallest of quantitative scales in a topic model: individual texts and individual topics. We will look at different weighting schemes for topic and topic word distributions, how to quantitatively characterize and visualize them, and then how to compare them to traditional literary criticism. As it turns out, the expressiveness of a topic model functions differently depending on the context in which we depict its data. To show this I will turn our attention to the literary-bibliographic focus of my Master's thesis, Emily Dickinson's "fascicle" books of poetry.

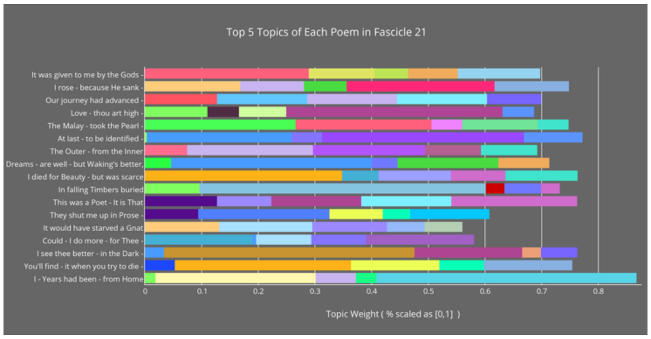

Figure 2. The topics of several Dickinson poems, displayed proportionately and in the order of a fascicle

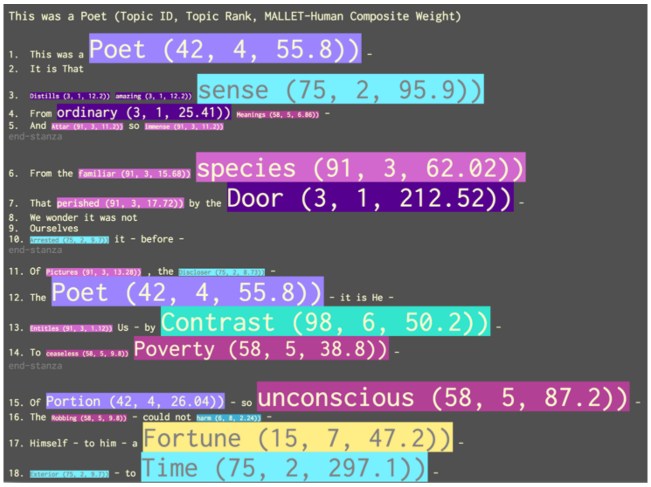
Emily Dickinson died in 1886, leaving behind in a small, wooden box an unpublished trove of poetry numbering near 2,000 individual works. Many of those poems were bound, hand-sewn into tiny books that have come to be known as her "fascicles." While her poems were being prepared to be published, a family feud arose that split the collection of her manuscripts, and also resulted in the fascicle ordering of her poems being lost for years. A long-studied, now-canonical poet, Dickinson is considered a proto-modernist, someone whose style influenced many of the American poets of the early twentieth century. However, given the size of the task, a comprehensive assessment of every piece of her writing has rarely been attempted. It would not be until the mid-twentieth century that the painstaking effort to rediscover those original orderings was made by bibliographers, notably R.W. Franklin. With that work completed, Dickinson scholars like Eleanor Elson Heginbotham, Sharon Cameron, and others have provided assessments of a select few of these orderings using all of the critical tools at their disposal honed by years of reading Dickinson: interpretations that pay attention to style, context, biography, history, textual studies, and more. Even so it just may not be humanly possible to provide a comprehensive perspective of her writing via such individual attentiveness. Dickinson's poems and their bibliographic history therefore present a fortuitous and somewhat unique set of circumstances for digital humanists. Her oeuvre as a poet is large enough in size to be mathematically modeled. There is a known ordering to much of her works. And her words are "truth told slant" enough in their polysemy to problematize a topic model's expectations of the relationships between them – even at the level of the individual line, let alone across several works.



```
This was a Poet (Topic ID, Topic Rank, MALLET-Human Composite Weight)

1.  This was a Poet (42, 4, 55.8)) -

```

Figure 3. A Dickinson poem viewed in a composite weighting scheme that utilizes both topic model weights and the considerations of a literary critic

While digital humanists still want to closely consider our objects of study away from computation, we also want to consider them from these new perspectives that digital modeling methods provide. We tend to bounce between considerations of model-induced order and the contextualizing work done by human-imposed orderings. This talk will provide a case study of how those differing worlds of order relate, how they sometimes either complement or contrast with one another. By combining the outputs of a topic model with the context of Dickinson's fascicle orderings, for instance, one can make quick comparisons between the qualitative discursive relationships of her poems and the quantitative relationships established by a topic model of them. I will introduce TWiC and its publication view to attendees as a means of exploring topic models, showing how it can be used to facilitate close readings of texts that focus on model data as well as on prior humanities criticism of those texts. This exploration will take us from the patterned, colorful shapes of TWiC to several types of analytic visuals that unweave the probabilistic threads of a topic model. By the conclusion, we will be able to proportionally compare the interpretations of a Dickinson critic and a topic model of Dickinson's poems as they are situated in the fascicle books.

Data Visualization in Archival Finding Aids: A New Paradigm for Access

Anne Bahde
anne.bahde@oregonstate.edu
Oregon State University Libraries and Press
United States of America

Cole Crawford
cole.crawford@oregonstate.edu
Oregon State University, United States of America

Archival finding aids (also called collection guides) are meant to enhance access to archival collections for researchers, and have been presented online for almost two decades. However, researchers still struggle to understand and use them, and the poor functionality of finding aids can often impede the research process. Online finding aids frequently violate many tenets of basic web usability by presenting large blocks of text, complex collection hierarchies, and connections between relevant materials in arcane and unintuitive formats. Many scholars in the humanities have struggled with archival discovery and navigation systems in the course of their research or teaching; cumulatively, these individual annoyances add up to significant interference in the production of humanities scholarship in the humanities.

Ciaran Trace and Andrew Dillon have argued that user problems with archival finding aids may be rooted in the system of power inherent in these tools. According to Trace and Dillon, the traditional archival finding aid has always "reflected, privileged, enabled, and given control to the writer (archivist) more so than to the receiver (researcher)" (Dillon 2012). Users of online finding aids are merely receivers of the information, and in many systems have no control over how the information is presented, or even what information is presented. As a static document, the finding aid limits interpretive possibilities and aggregate analysis, because it cannot be (re)configured to meet users' research needs. Passive, search-based finding aid systems hinder researchers' potential for creativity, and obscure opportunities for serendipitous discovery.

Digital humanities modalities suggest compelling ways to disrupt this power paradigm. Johanna Drucker has called for "knowledge-generating visualizations," which empower the user to produce new interpretations and arguments through manipulation and augmentation of the data presented (Drucker 2014). Tim Sherratt has advocated for the development of digital collection interfaces that enable users to visualize, augment, problematize, and critique collections and collections data (Sherratt 2011). These appeals invite questions about how users might respond to finding aids that present archival information in newly visual ways. What happens for the user when archival finding aids are stretched beyond traditional modalities to invite new interpretations of collections?

This presentation will introduce multiple models for including visualizations in both individual finding aids and discovery systems. Using case studies derived from pilot projects at Oregon State University's Special Collections and Archives Research Center (SCARC), the presenters will discuss models that allow the researcher (and the archivist) to compare, match, recognize, distinguish, arrange, combine, construct, and organize data across a constellation of data points in ways that traditional, textual finding aids cannot. Models discussed will include proof-of-concept designs for interactive geographic timelines, force-directed network graphs, circle packing units, cluster force designs, alluvial diagrams, and treemaps that enable "distant reading" of a finding aid or corpus of finding aids. These visualizations allow users to identify patterns over time or space, relationships between collections, proportions between categories of data, and more. The presenters will explore how these visualizations can impact every stage of the research process, including topic exploration, identification of relevant archival collections, and establishing context and background.

Figure 2: Example of force-directed network graph of related collections

Using several enhanced finding aids designed to promote access to archival materials, the presenters will examine practical considerations for researchers and archivists interested in creating visually enhanced digital finding aids. These considerations include platform selection, tool design, scalability, and data repurposing. SCARC faculty and staff work on multiple platforms, each tailored to specific project needs; choosing the right digital platform is critical to the long-term sustainability of a project, and this choice has only become more difficult with the proliferation of content management systems, digital publishing tools, and repository solutions.

Similarly, selecting the right development frameworks and types of visualizations for a certain data source can either enhance or limit a project’s potentialities. While the presenters have found success with libraries and tools such as d3.js, Leaflet, Sigma.js, and RAW, each archival discovery environment bears its own research complications which necessarily inform tool selection. The presenters will also talk about how both digital products and data production processes scale by considering project management and data entry workflows. Finally, the presenters will address how researchers can incorporate, clean, and repurpose existing data sources into new digital finding aids by examining a legacy finding aid that was repurposed and enhanced.

New research in the humanities often begins with consultation of finding aids and archival research environments. If access to archival collections is obscured by finding aid presentation and form, opportunities for progressive and provocative scholarship are concealed. Redesigned interfaces have the potential to invite new interpretations of collections, to encourage experimentation with research methods, and to plant new seeds of inspiration. Pairing new paradigms of visualization with recently proposed concepts of arrangement and description can open exciting possibilities; rhizomatic organization, for example, interrupts traditional hierarchy, structure, and power paradigms, and suggests a dynamic, acentric finding aid with multiple access points. If archivists create tools to make the archival research process adaptive and dynamic for users with different research needs, humanities scholars are empowered to pursue paths of inquiry never before revealed by traditional access tools.

Introduction

How do people look at and experience art? Which elements of specific artworks do they focus on? Do museum labels have an impact on how people look at artworks? The viewing experience of art is a complex one, involving issues of perception, attention, memory, decision-making, affect, and emotion. Thus, the time it takes and the ways of visually exploring an artwork can inform about its relevance, interestingness, and even its aesthetic appeal. This paper describes a collaborative pilot project focusing on a unique collection of 17th Century Zurbarán paintings. The Jacob cycle at Auckland Castle is the only UK example of a continental collection preserved in situ in purpose-built surroundings. While studies of the psychology of art have focused on individual works and distinctions between representative/non-representative topics, no work has been completed on the aesthetic appreciation of collections or of devotional themes. In this paper, we report upon the novel insights eye-tracking techniques have provided into the unconscious processes of viewing the unique collection of Zurbarán artworks. The purpose of this pilot study was to assess the effects of different written interpretation on the visual exploration of artworks. We will discuss the potential implications of these techniques and our understanding of visual behaviours on museum and gallery practice. The project brings together established research strengths in Spanish art history, experimental psychology, digital humanities, and museum studies to explore, using eye-tracking techniques, aesthetic reactions to digital representations of the individual Zurbarán artworks as well as the significance of the collection as a whole.

Overview

Our experience of art develops from the interaction of several cognitive and affective processes; the beginning of which is a visual scan of the artwork. When regarding an artwork, a viewer gathers information through a series fixations, interspersed by rapid movements of the eye called saccades. The direction of saccades is determined by an interaction between the goals of the observer and the physical properties of the different elements of the scene (e.g. colour, texture, brightness etc). Importantly, studying eye movements offers an insight that does not depend on the participants' beliefs, memories or subjective impressions of the artwork. Previous eye tracking research has highlighted the potential to transform the ways we understand visual processing in the arts (see for example Brieber 2014; Binderman et al., 2005) and at the same time offers a direct way of studying several important factors of a museum visit (Filippini Fantoni et al., 2013; Heidenreich & Turano 2011; Milekic 2010).

Zurbarán's cycle of Jacob and his Sons has been on display in the Long Room at Auckland Castle for over 250 years. It is the only cycle to be preserved in purpose-built surroundings in the UK, and one of very few of its kind in the world. It has a long history in scholarship (Baron & Beresford 2014), but many key aspects of its production and significance have not yet been fully understood. In this study we used eye-tracking in the first stage of exploring audience experience of the extensive Spanish art collections of County Durham, of which the 13 Zurbarán artworks (there are actually only 12 Zurbarán artworks, the 13th Benjamin, is a copy by Arthur Pond) are a key part of, to investigate the ways in which audiences look at Spanish art, how aesthetic experience is evaluated and whether audiences can be encouraged to approach art in different ways. This pilot project primarily investigated how participants visually explore artworks and provides new insights into the potential eye-tracking has to transform the ways we understand visual processing in arts and culture and at the same time offer a direct way of studying several important factors of a museum visit, namely to assess the effects of label characteristics on visitor visual behaviour.

Method

The aim of this study was to determine whether the accompanying written context influences how digital artworks are visually experienced. Whether contextual information impacts on where participants first look (first fixation), if gallery labels influence the time participants choose to view artworks and, especially, whether it influences their aesthetic appreciation of the works. We expected viewing time for artworks and corresponding labels to be predicted by participants' subjective experiences, artwork related features, and contextual factors. Accordingly, we measured viewing time, fixation, and saccades for each artwork and corresponding label using a fixed eye tracking technology (Tobii TX300) in a laboratory setting.

Forty Six students from the University of Durham participated in this study. All participants had normal or corrected vision, no formal training in arts or art history and received course credit for taking part. All participants gave informed consent. The study was approved by Durham University's Department of Psychology Ethics committee. A third of the participants were randomly assigned to the Museum Context group (nMC =16), who inspected digital images of the paintings in conjunction with the contextualizing labels currently in use at Auckland Castle, which rely heavily on relating the content of individual compositions to the words of Jacob in Genesis 49; a third to the Aesthetic Context group (nAC = 15), who received labels foregrounding issues of aesthetic and interpretive interest; and the final third to the No Context group (nNC = 15), who received only basic attribution data: title of composition, name and date of artist, date of composition, and nature of medium (i.e. "oil on canvas").

All stimuli were taken from Auckland Castle's collection of Jacob and his Twelve Sons by Francisco de Zurbarán. Each participant viewed high-resolution digital reproductions of the original artworks presented on the

Tobii TX300 screen based eyetracker. The stimuli were presented in the same sequence for all participants.

Results

Previous authors have shown that when a human being is portrayed in a painting, gazing behaviour is mostly focused on the human figure, independently of contextual elements also depicted in the image. In particular, attention is given to the face area, and it plays a fundamental role in aesthetic judgment (Ro et al., 2007; Massaro et al., 2012; Villani et al., 2015). Given these considerations, three key regions of interest (ROI) were identified; the head, the clothes and the contextualising element. Saccades and fixations were identified offline in Tobii Studio using the default algorithm (onset/offset criterion of 70 degrees/second and a minimum dwell time of 80ms). The key variables of interest for each ROI were (1) Frequency of First Fixation, (2) Time to First Fixation and (3) Total Fixation Duration.

When comparing the first fixation data across the three participant groups (Museum Context group (MC), Aesthetic Context group (AC) and No Context group (NC)), it possible to see an interesting trend (Fig 1) that suggests that contextual labelling appears to change the proportion of participants fixating on the face. The study revealed that the AC labels succeeded in disbursing the gaze more effectively than those that are current MC labels. In all thirteen paintings, evidence shows that participant visual behaviour changed in response to the written interpretation. This suggests that an aesthetic context labelling approach is more successful in stimulating and/or training the gaze than one rooted in theological extrapolation.

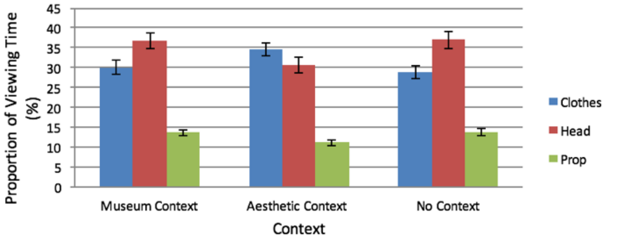

Figure 1: Graph highlighting the proportion of viewing time spent fixating on the face.

The pilot study also found that contextual labelling has a significant effect on influencing levels of aesthetic appreciation, and on the ways in which the gaze can be trained and/or manipulated to engage with areas of interest that would otherwise be overlooked. Reorienting the content of individual labels away from scripture and towards questions of aesthetics and interpretation produced a statistically significant reduction in aesthetic appreciation, which, given that the face is a key driver of aesthetic judgements, is consistent with the finding that the aesthetic context also reduced the participants dwell time on the face.

This paper will also discuss a how participants identify and rank the artworks in terms of authenticity and value. By ranking compositions, we will cross-reference attitudes with the prices (all different) paid by Bishop Trevor at auction in 1756, considering how aesthetic tastes have changed.

Summary and Conclusions

To date, studies of museum and gallery visitor behaviour primarily investigate how people behaviourally and cognitively respond to the design and layout of exhibits. However, they largely ignore the behavioural responses at the 'exhibit- face' (vom Lehn and Heath 2006) or the 'fat moment' (Garfinkel 1967) of visitors' action. Eye-tracking techniques have provided novel insights into the unconscious viewing processes of the 'fat moment' of the unique collection of Zurbarán artworks. The study highlighted statistically significant variations in levels of aesthetic appreciation. More importantly, the experiments indicated that by changing the written interpretation gaze can be redirected towards areas of conceptual significance, challenging the face bias which traditionally plays a fundamental role in aesthetic judgment.

Access to cultural heritage data: a challenge for the Digital Humanities

Access to Cultural Heritage data is a key issue in the future development of Digital Humanities (Murray-Rust, 2013). Cultural Heritage data encompass digitized resources (scanned artefacts) as well as the attached metadata, annotation or further enrichments, all of which are a necessary basis for reliable computational research. Access to high quality Cultural Heritage data and metadata is, in that sense, the condition for reliable, performing and verifiable research in many arts and humanities fields - and not just of interest to librarians and archivists.

One of the core challenges of giving access to high quality Cultural Heritage data is often the lack of institutional connection between local GLAM Institutions (e.g. Galleries, Libraries, Archives and Museums), infrastructures and research (University College London, 2010; Higgins, 2013). The initiative we want to present in this paper addresses this issue by bringing together several supra-national infrastructures. These research infrastructures develop a common online environment that allows all the relevant actors to connect and improve together access to Cultural Heritage data. This project is based on in-depth exchanges on recognized standards as well as on strategies of access, data curation and management, licensing, and an effort towards open data (Romary et al., 2016).

The "Cultural Heritage Data Reuse Charter" is currently being developed by several organisations and projects grouped together within a steering committee: DARIAH-EU, Europeana, Clarin, E-RIHS and APE together with the European projects Parthenos, HaS and IPERION-CH .

It offers a comprehensive framework regarding all aspects relevant to co-operations revolving around access to and reuse of Cultural Heritage data.

The Cultural Heritage Data Reuse Charter: an encompassing cooperation framework

The Cultural Heritage Reuse Charter is an online environment dedicated to all actors taking part in scholarly reuse of digital data generated by Cultural Heritage Institutions. It addresses five actors: Cultural Heritage Institutions, Cultural Heritage Labs, Researchers, Data Centers and Research Institutions.

- Cultural Heritage Institutions (GLAM) are considered in their function as curators of collections and objects in their physical form and as potential primary initiators of corresponding digital surrogates, from basic descriptions (catalogues of collections, metadata for specific objects) to more elaborate outputs (scans, 3D models, physical analyses, etc.) (Ray, 2014).
- Primary data can be hosted by CHIs or by Higher Education Institutions like universities, but they are in many cases curated by dedicated data centers. These centers play a key role in guaranteeing the stability, the visibility and the long time availability of the primary data. The engagement expected from them in the context of the Charter is of a more technical nature and should ensure a concrete implementation of the CHI-researcher relationship.
- Cultural Heritage laboratories have a high-level expertise in Cultural Heritage. They give essential insights into Cultural Heritage history, technologies, environment, and alteration.
- Researchers are invited to sign in person, independently from the institution for which they are working at the time they sign the Charter. However, academic institutions (departments, universities, research institution or funding agencies) wishing to sign the Charter, or even make it a requirement for their members or the projects they fund or host, are welcome to do so as well.

The Charter environment allows all five actors to declare general principles (common work ethics), and more broadly all the relevant information needed to understand how a given dataset can be reused. It allows its users to get in contact with partners they would want to work with. Institutions can declare their collections; researchers their research interests and existing publications so that these are connected together. Doing so, all of them always have the possibility to define precisely which aspects of their profile information they wish to make public and which not.

By joining forces, and by sharing the information associated to Cultural Heritage collections, the Charter will help document the knowledge generation process and, consequently, increase the quality of data and metadata accessible to research.

Signing the Charter implies making a statement about the technical quality of the data to be reused, or the data derived by such a reuse. The implementation of appropriate standards is considered a key node for the stabilization of data access (Romary, 2011). More broadly, the Charter offers a concrete implementation framework for the FAIR principles (make the data findable, accessible, interoperable and reusable).

The online environment in practice

The principles described below are addressed by a series of components allowing to define the conditions of reuse for each type of data. The Charter environment offers a framework that can be either picked among a set of recommendations or formulated in a text field by the concerned institutions or actors according to their needs and wishes.

This framework encompasses all questions related to the reuse of Cultural Heritage Data:

- Long-term and persistent access to metadata, texts, images (in the case of a manuscript for instance: archival metadata, scan of the manuscript, transcription, annotation)
- Licensing of the content (linking to relevant documentation allowing for instance researchers to gather information on licensing and citation practices they often lack)
- Formats and standards (also connecting to further information)
- Enrichments (connection of scholarly work and CHI work)
- Dissemination of both CHI information and research (visibility of the work of all stakeholders)
- Retro-provision (communicating enrichments based on CHI data to the CHI they originally emanate from)
- Quality control at all levels according to appropriate standards.

In practice, users of the Charter register in the online environment in their primary function as Cultural Heritage Institution, Researcher, Cultural Heritage Lab, Data Center or Research Institution. Identification of entities are realized on the basis of existing standards such as ORCID for researchers.

In the researcher profile, three main areas are to be defined by the registered user. First, he/she has to abide to the reuse principles defined by the Cultural Heritage Institutions regarding the collection he/she wants to work on; this is the “use of primary data” area. Second, he/she has to declare the dissemination principles he/she favours. In this “dissemination of secondary data” area, he/she can gather information on licences. The third area is that of the “cooperation ethics”, in which the researcher declares that he/she will follow best practices in citing the other Charter partners involved in his/her endeavour. This threefold profile is the basis on which the researcher can reach out to institutions or collections he/she wishes to work with.

Timeframe

The Cultural Heritage Reuse Charter is currently under development. Workshops in which information will be gathered especially on the expectations of Cultural Heritage Institutions will take place in Berlin (November 2016), Paris (November 2016), Rome (January 2017) and Dublin (February 2017). Additional input from the other actors is gathered in parallel (interviews). A soft launch of the web interface is planned for the summer of 2017, so that the interface as well as the benefits for the first signatories can be demonstrated in Montreal .

This abstract is in English in order to reach the widest possible community. Presenting the paper in French or having the slides to the presentation in French would be possible as well.

Toponyms as Entry Points into a Digital Edition: Mapping Die Fackel (1899–1936)

Adrien Barbaresi
adrien.barbaresi@oeaw.ac.at
Austrian Academy of Sciences, Austria

Introduction

The significance of place names exceeds the usually admitted frame of deictic and indexical functions, as they enfold more than a mere reference in space. In the western tradition, a current of reflexion which seems to date back to the 1960s has provided the theoretical foundations of the "spatial turn", whose epitome is the concept of space as emergent rather than existing a priori, and composed of relations rather than structures (Warf, 2009). The emergence of current named "GeoHumanities" (Dear et al., 2011) or "Spatial Humanities" (Bodenhammer et al., 2010), has prompted for a transfer of research objects between disciplines as well as an enforcement of the spatial turn in practice through specific methods of analysis. The common denominator consists in opening up new spaces and experimenting in a transdisciplinary perspective (Domínguez, 2011) in a field which has been evolving at an exponential pace since the last decade (Caquard and Cartwright, 2014).

In this paper, I introduce a visualization of collocations of toponyms in the satirical literary magazine Die Fackel ("The Torch"), originally published and almost entirely written by the satirist and language critic Karl Kraus in Vienna from 1899 to 1936. This work carries heterogeneity at its core and contains a considerable variety of toponyms (Biber, 2001) which are highly significant because of the multinational nature of the Austro-Hungarian empire and the later formation of a territorially diminished state.

In order to provide an additional, synthetic access to a digital edition of the work which is already available online (AAC-Fackel corpus), I set out on a distant reading experiment leading to maps meant to uncover patterns and specificities which are not easily retraceable during close reading. I focus on the concept of visualization, that is on the processes and not on the products (Crampton, 2001), and present them together with a critical apparatus, by giving a theoretical perspective on what is being shown and seen. In fact, digital methods in humanities ought to be criticized (Wulfman, 2014) and the cartographic enterprise bears both a thrill and a risk: "adding more to the world through abstraction", and "adding to the riskiness of cartographic politics by proliferating yet more renders of the world" (Gerlach, 2014).

Extraction of toponyms

The particular task of finding place names in texts is commonly named place names extraction, toponym resolution, or geocoding. A first stage involves the identification of potential geographic references, while a second stage resides in a disambiguation process (Leetaru, 2012). Toponym resolution often relies on named-entity recognition and artificial intelligence (Leidner and Lieberman, 2011). However, knowledge-based methods using fine-grained data – for example from Wikipedia – have already been used with encouraging results (Hu et al., 2014).

The present endeavor grounds on a specially curated gazetteer: during the 20th century there have been significant political changes in Central Europe that have severely affected toponyms, so that geographical databases lack coverage and detail. Consequently, the database developed at the Austrian Academy of Sciences (Academy Corpora) in cooperation with the Berlin-Brandenburg Academy of Sciences (Language Center) focuses on Europe and follows from a combination of approaches: gazetteers are curated in a semi-supervised way to account for historical differences, and current geographical information is used as a fallback. Wikidata API and the Geonames database are used to build the database semi-automatically.

The tokenized files of works to be analyzed are filtered and matched with the database by finite-state automatons (Barbaresi and Biber, 2016): toponyms (single or multi-word expressions) are extracted using a sliding window. A cascade of filters is used: current and historical states; regions, important subparts of states, and regional landscapes; populated places; and geographical features. Disambiguation being a critical component (Leetaru, 2012), an algorithm similar to Pouliquen et al. (2006), who demonstrated that an acceptable precision can be reached that way, guesses the most probable entry based on distance to Vienna (Sinnott, 1984), contextual information (closest-country, last names resolved), and importance (place type, population count). The results are projected on a map of Europe using TileMill.

From collocations to lines of thought

In a further analysis, I visualize co-occurrences of extracted toponyms, which can be considered to be a subset of GeoCollocations (Bubenhofer, 2014), in order to draw sequences, airborne lines following their order of appearance. The word "network" is to be used with circumspection as Latour (1999) suggests. Although it is ubiquitous in the terminology of the spatial turn, the now predominant interpretation in the sense of the World Wide Web suggests an immediacy which is contrary to the acceptions it had before, so that the concept of "meshwork" is more appropriate (Ingold, 2007). I thus interpret Figure 1 as a general meshwork which makes it possible to visualize paths depicting chains of thought (Gedankengänge) as well as their intensity (well-trodden or seldom). If they may reveal spatial patterns that would otherwise remain hidden in texts (Bodenhammer et al., 2010), these linkages are also "mappings and tracing imposed on the data" (Wulfman, 2014) which are not meant to be interpreted without further filtering.

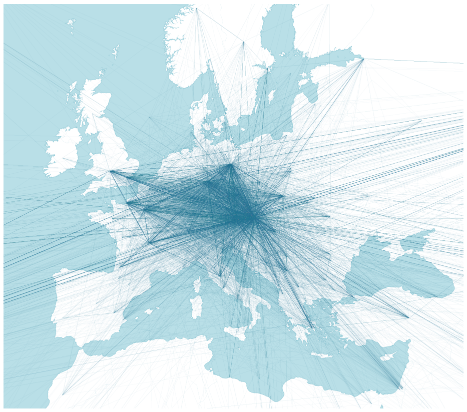

Figure 1. Unfiltered map of toponymic co-occurrences

A rhizome as entry to Die Fackel

That is why I refine the map by selecting a subset of the co-occurrences – the maximal distance between two extracted place names is fixed to twenty tokens – and by color-coding qualitative features – the typology of place names and the axis of time. The most frequent place names are printed out. Surfaces (regions for instance) cannot be represented as such because of historical evolutions and because of the difficulties of linking surfaces without tampering with map readability. Coastlines are depicted in gray to give a sense of orientation, no boundaries are drawn, as they are of a changing nature and may superimpose an artificial reading of the map (Smith 2005).

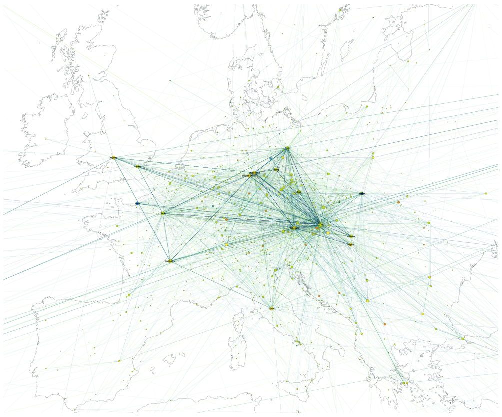

Figure 2. Refined analysis (size proportional to corpus frequency; yellow: sovereign territories; orange: regions; green: populated places; blue: geographical features; time axis represented by a gradient from light green to dark blue)

The notion of rhizome has been used in corpus linguistics by Scharloth et al. (2013) to qualify discourses captured by collocation graphs, it has originally been coined by Deleuze and Guattari (1987 [1980]). This concept is particularly adequate for Kraus, as the Austrian satirist has always been concerned by the multiple aspects of discourse and reality. In addition, his work in Die Fackel evades distant reading processes because of the number of citations used and its ever present and extensive usage of parody. It would be vain to design an authoritative cartography of Die Fackel: following from the principles of heterogeneity and "asignifying rupture" (ibid.), the lines are frequently interrupted. Phenomena in the low-frequency range are filtered out by the human eye, but clusters and interpretation cues may emerge which provide a different access to the work. In this regard, Figure 2 depicts a rhizome connecting heterogeneous information, just as we are all "traversed by lines, geodesics, tropics, and zones marching to different beats and differing in nature" (ibid.).

Conclusion

I have presented a distant reading experiment which consists of connecting toponyms extracted and projected on maps. The latter are meant to be released as an additional feature to the existing digital edition. The Software and gazetteer will be made available under open-source licenses, for development files (please refer to the Github repository). The first example displays unfiltered lines of thought, whereas the second one grounds on a refined analysis and lets the practical image of a rhizome emerge. While Die Fackel criticizes mechanical, instrumental language (Hirt, 2002), the "well-informed" linguistic instruments can help materializing dots or sequences, but not without "human" intervention. The filtering steps on the projection echo the hermeneutic circle of the philological tradition; they also make computed information visible and apprehensible which could remain "blind" otherwise (Barbaresi, 2012).

This is not an authoritative cartography of Die Fackel but rather an indirect depiction of the viewpoint of Kraus and his contemporaries. Drawing on Kraus' vitriolic recording of political life, toponyms in Die Fackel tell a story about the ongoing reconfiguration of Europe. As the map conveys the uncanny sensation that the continent is a field on which points east and west are projected, the lines of force entangle European countries and capitals. Their spatial patterns document an inclination for major cultural centers, whereas the chronological dimension captures a major shift towards the end of publication: the force field intensifies as its range narrows, showing both the interplay of major European powers of the time and the emergence of transatlantic (westwards) and transeuropean (eastwards) relationships. This evolution can be read as an intensification of tensions and a prefiguration of other schemes, this time of military nature.

Perseids and Plokamos: Weaving pedagogy, data models and tools for social network annotation

Marie-Claire Beaulieu

The Perseids Project is developing a platform on which students and scholars engage in collaborative acts of scholarship and research on ancient texts (Almas & Beaulieu, 2016). A core value of the project is the focus on pedagogy and the development of undergraduates as researchers. This is complemented by an emphasis on reuse and sharing of tools, data and resources. We keep these values in mind as we develop infrastructure to support complex workflows for the production of new forms of digital publications that are both machine-actionable and human-understandable. In this paper we describe one specific research activity undergraduate students have been conducting on Perseids, the annotation of the social networks of mythological characters. We discuss how opportunities and challenges, both pedagogical and technical, have presented themselves throughout multiple iterations of this effort, and how we evolved the architecture, information structures, and pedagogical workflows in response. We will use our findings to guide future decisions on when to build or reuse tools, and to formulate empirically founded recipes and approaches for specific user scenarios and data types.

The social network annotation project was motivated by an interest in teaching how to produce interpretations of mythological figures and texts. As explained by Schacht, annotation is an activity that is well known to produce deep engagement with a text in the form of close reading while promoting collaboration and conversation among students (Schacht 2016). In this case, we needed to produce interpretations that would be anchored in the primary materials and allow for a representation at the conceptual level. We decided to annotate *Smith's Dictionary of Greek and Roman Biography and Mythology* (Smith's), which offers both a complete narrative for each figure and references to the primary sources on which the narrative is based. This allowed for a double learning outcome. For instance, students would observe that Scylla is directly connected only to first and second generation Titans who represent monstrous or rebellious aspects of nature such as Typhon (volcanoes) and Charybdis (whirlpools). In addition, by following and researching the references to the primary sources, students would note that ancient texts characterize Scylla with words such as "rabid", "aggressive", and "deadly". In this way, students learned that mythological genealogies and social connections are the links which the Greeks made between different concepts represented by the mythological figures. By studying the words with which ancient texts characterize mythological figures, the students understood the value (positive or negative) associated with these concepts in Greek culture.

As we always look to reuse rather than build from scratch when possible, we developed an annotation workflow for this activity using Hypothes.is, an existing open source annotation tool (on the use of Hypothes.is in the classroom, see Kennedy 2016) . We also selected the Standards for Networking Ancient Prosopographies (SNAP) ontology for representation of the social network in the annotations, and the Open Annotation (OA) data model for serialization of the data (Sanderson et al. 2013a) Hypothes.is lacked support for controlled vocabularies, but offered free-form text entry as well as tags, worked on any website, and provided an API for retrieval of the annotations. We prepared explicit tagging instructions for the students with rules that would enable us to apply the controlled terms and data model to the annotations. Students submitted lists of their annotation URIs to the Perseids platform for ingest, review and publication of the data. Perseids software retrieved the students' data from the Hypothes.is API, and upon ingest, applied a transformation, producing OA-compliant annotations using the SNAP ontology. Once the annotations were approved by reviewers in Perseids, we exported the data for final publication via the GapVis interface, to which we added a social network visualization and support for Canonical Text Services data sources.

We completed two full annotation rounds with separate student groups using this workflow. A key finding from a review of the data from the first round was that the lack of ability to visualize the networks at the time of annotation left too much room for error in the directionality of the annotations (On the efficacy of visualization in computer-assisted learning, see Baek and Lane 1988). Despite having explicit instructions on how to identify the subject and object of the annotations, it was difficult for both the students and the reviewers to appreciate their importance without being able to see how their choices impacted the final data. We ended up, for example, with annotations which identified a mother as the son of her child. We tried to address this in the second round by providing even more precise instructions, but the same mistakes were made. Our instructions and transformation rules also became more complex because, having identified the pedagogical significance of the characterizations, we asked students to annotate them as well as the social network connections. Through this process it became clear that we were trying to use the Hypothes.is tool in a way which was very different from the use cases it was developed to support. As a result, we had a workflow which required too much focus on following complex written instructions. This detracted from the pedagogical effectiveness of the activity as well as the overall quality of the resulting annotation data.

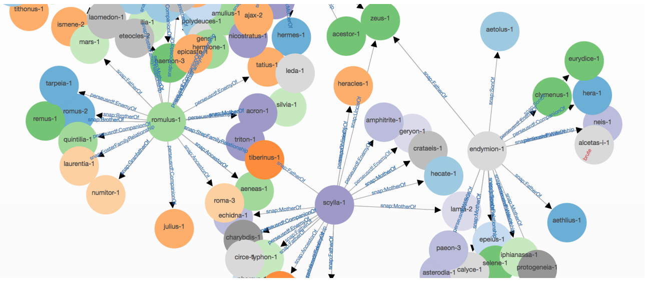

Figure 1. Plokamos network visualization based on students' annotations

At the end of this experimentation phase, we undertook a process of surgical development to address these concerns. With a much clearer understanding of our requirements, and the importance of immediate, visual feedback to the annotation and review process, we developed a targeted interface for semantic annotation which would work on any source text and allow for the data network to be visualized during the annotation process (see Fig. 1). The tool we developed - Plokamos, which is Greek for "something woven" - is a Javascript application backed by an RDF-based triple store. The Plokamos interface is also designed for reuse in other workflows and by other teams. It can be embedded into an existing application and can be extended to support other ontologies and rdf-based annotation bodies. At all times, the data itself remains separate from the tool and available for export and reuse. The configuration is also externalized from the code, and managed, along with the data, as RDF graphs. In our current deployment of Plokamos we reuse Perseids' user model, the Nemo Citable Text Services text browsing interface, and the Apache Marmotta triple store, and we continue use of the OA data model and the SNAP ontology.

We can also see the evolution and objectives of the project reflected in the underlying data structures of the annotations themselves. The annotations consist of a frame with metadata pertaining to their type, provenance and the targeted data source; linked from the frame is the annotation body containing the actual semantics of the annotation. We examine these structures at two architectural levels and from two usage perspectives.

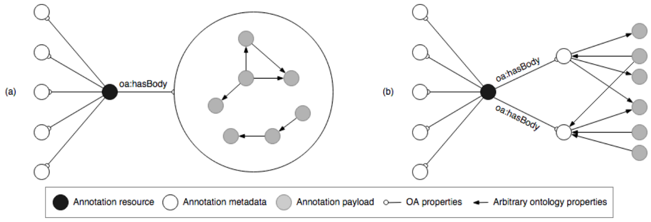

Figure 2. Graph- and Resource-based anchoring of annotation bodies

In designing the body we considered different topologies (of the connection between body and frame; and of the body itself -- structural multiplicity, see Sanderson et al, 2013b) and the compromises they represent between clarity of the annotation body and ease of traversal between annotation frame and body. An annotation body can be embedded into a distinct and uniquely named graph which is referenced by the annotation frame (see Fig. 2 (a)); or it can be anchored through one or more identifying resources which are referenced as the annotation body (see Fig. 2 (b)). The former approach enables quick and easy delineation of individual annotations and allows for complex topologies with multiple graph components. The latter approach offers less flexibility in the structure and complexity of the individual annotations but linking the payload with intermediate resources provides easier pathways to their reuse in other graphs, queries and analyses.

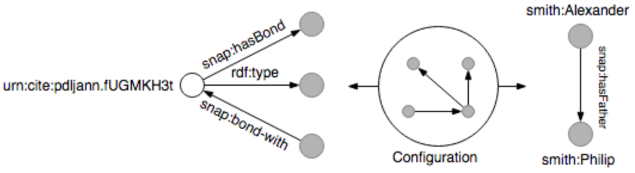

Figure 3. Transformation between machine-actionable and human-readable topologies

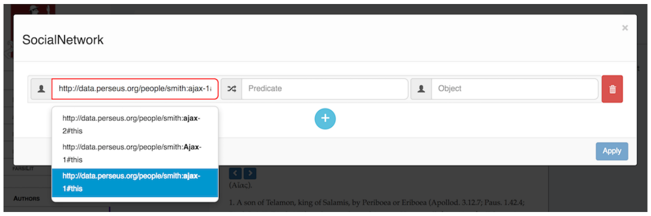
The need for the resulting annotation bodies to be understandable by humans as well as algorithmic processing is another factor impacting the data model. Both user groups have different requirements for the topology of the annotation data. Humans may prefer a more direct representation of the data in which object-relational structures are left implicit, while algorithms are not only indifferent to indirect construction but benefit from a more explicit and formal description of the underlying data.



SocialNetwork

(Αἴας).

1. A son of Telamon, king of Salamis, by Periboea or Eriboea (Apollod. 3.12.7; Paus. 1.42.4;

Figure 4. Annotation interface for entry of social network data

We have used the design of the Plokamos' user interface to help us mediate between these different perspectives. The interface guides the users through the annotation process with a simplified representation of entities and relations in the form of unadorned subject-predicate-object triples (Fig. 4), offering pre-configured choices to to help ensure data integrity, and we use a graph-based system of configuration to transform and expand to the more complex structures in the final annotation data.

Through this iterative approach to supporting the social network annotation activity, putting our core values of pedagogy and reuse front-and-center, we have been able to explore the pedagogical effectiveness of annotation as a learning method with a fairly low initial investment of resources. This allowed us to validate the importance of supporting this activity and refine our understanding of the architecture and data models that would be best suited to it. We were then able to approach the development of custom tools more efficiently, while still designing for maximum extensibility and reuse. The resulting web interface with its RDF-based data source and configuration can be used on a wide variety of existing classroom resources, and expanded upon to support new use cases with varying annotation body, target types, and visual representations.

Introduction

Spam, or unsolicited commercial communication, has evolved from telemarketing schemes to a highly sophisticated and profitable black-market business. Although many users are aware that e-mail spam is prominent, they are less aware of blog spam (Thomason, 2007). Blog spam, also known as forum spam, is spam that is posted to a public or outward facing site. Blog spam can be to accomplish many tasks that email spam is used for like posting links to a malicious executable.

Blog spam can also serve a couple of unique purposes. First, blog spam can influence purchasing decisions by featuring illegitimate advertisements or altering a product's review. Second, blog spam can include content spam with target keywords designed to change the way a search engine identifies pages (Geerthik, 2013). Lastly, blog spam can contain link spam which spams a URL on a victim page to increase the inserted URLs search engine ranking. Overall, blog spam weakens search engines' model of the Internets popularity distribution and leads to malicious pages increasing in popularity. Much academic and industrial effort has been spent to detect, filter, and deter spam (Dinh et al, 2015, Spirin and Han, 2012).

Less effort has been placed in understanding the underlying mechanisms of spambots and botnets. One foundational study in characterizing blog spam (Niu et al, 2007), provided a quantitative analysis of blog spam in 2007. This study showed that blogs in 2007 included incredible amounts of spam but does not try to identify linked behavior that would imply botnet behavior. A later study on blog spam (Stringhini et al, 2015) explores using IPs and usernames to detect botnets but does not characterize the behavior of these botnets. In 2011, a research team (Stone-Gross et al, 2011) infiltrated a botnet which allowed for observations of the logistics around botnet spam campaigns. Overall, our understanding of blog spam generated by botnets is still limited.

Related Work

Various projects have attempted to identify the mechanics, characteristics, and behavior of botnets that control spam. In one important study (Shin et al, 2011), researchers fully evaluated how one of the most popular spam automation programs, XRumer, operates. Another study explored the behavior of botnets across multiple spam campaigns (Thonnard and Dacier, 2011). Others (Pitsillidis et al, 2012) examined the impact that spam datasets had on characterization results. Luzezanu et al. explored the similarities between email spam and blog spam on Twitter (Lumezanu and Feamster, 2012). They show that over 50% of spam links from emails also appeared on Twitter.

Malay Reserved Land For Sale In Malaysial Semi-D And Strategic Location

Tue, 05/10/2016 - 10:29 — margotdorlandav6

One explanation I like Residential investment properties is i will be a realtor that has working experience in Residential properties. Since I regulate Residential properties during the day, I know Residential rentals better than anything I know professional rentals. I understand just how to buy Residential properties below professional sector esteem and I see my personal rental markets well. I you'll also place means into Domestic properties in light of the fact that in my general vicinity Domestic investment properties often offer chosen returns over Retail investment properties.Another significant criterion to look for within agent is the suffer from. Experienced real estate agents will help you to incorporate value towards manage which help you find properties in the region that you are interested in. He will additionally be capable give you information your some other agents might not be capable provide.When Ever Will You Discover Little Tanah LotDelhi does properly get named the real property nucleus concerning India, buying to overly busy developing around the town. The actual property market at Delhi shows scaled emerging height. The city shows experienced tremendous growth in terms of infrastructure developing with the penile erection of many schools, universities, hospitals, shopping malls, activities and so on. This is especially true in case of that NCR area. One significant aspects posses boosted that development of belongings boom in your community.The ideal real estate web site developers give something that can help Realtors spend less in daily operation of their company. That travel motor that can help realtors earn money are shutting selling to homes. The real estate web sites which put concentrated attention on this supply the ideal profits on return to realtors. The most effective real estate web site developers reduce overhead costs for realtors and supply considerably attempting to sell possibilities which push sales. Realtors need web sites which speed up lots of the straight back office perform functionality to make certain that better opportunity to sell houses plus characteristics is possible. Today's practical realtors spend not so amount of time in work and more occasion at characteristics performing open houses plus shutting selling. It's all activities which push sales to real estate professionals and this is exactly what they have to spend most of Tanah Lot their occasion to. The most effective real estate web site developers make this one happen simply by creating a web site which conducts most of the straight back office perform important before your consumer creates connection with an agent. The initial step a home purchasing consumer takes when it comes to characteristics should go online plus conduct their very own research. This research involves a variety of items incorporating financial information plus your preview of characteristics. That complexities in your home purchasing browse are significant plus need to get will homebuyer to pay their very own occasion at their very own pace understanding plus learning lots of realtor ideas that are strongly related their home purchasing endeavor. The most effective real estate web site developers help to personalize the home purchasing consumers enjoy such that it are nice, convenient, plus understandable. Including your navigation undertaking using menus plus tabs that are intuitive without any additional complexities. Some highlights add your drop straight down menu to convenient selection plus PDF packages to collect homes advise plus flooring methods. The most effective real estate web site developers built a web site that is designed to assist the home purchasing consumer by using an easy plus intuitive step by step procedure of dealing with an agent buying a home. Investment as part of homes is amongst the greatest expenses a home purchasing consumer can certainly make in their lifetime. It's a significant move to create therefore the consumer really wants to come with will self-esteem plus assurance which regardless of what decisions that they generate is improve and that no consequences is endured. The most effective real estate web site developers build a web site which guides the home

Figure 1: Browser rendering of the ggjx honeypot.

The underground ecosystem build around the botnet community has been explored (Stone-Gross et al, 2011). In a surprising result, over 95% of pharmaceuticals advertised in spam were handled by a small group of banks (Levchenko et al, 2011). Our work is similar in that we are trying to characterize the botnet ecosystem, focusing on the distribution and classification of certain spam producing botnets.

Experimental Design

In order to classify linguistic similarity and differences in botnets, we implement 3 honeypots to gather samples of blog spam. We configure our honeypots identically using the Drupal content management systems (CMS) as shown in Figure 1. Our honeypots are identical except for the content of their first post and their domain name. Ggjx.org is fashion themed, npcagent.com is sports themed, and gjams.com is pharmaceutical themed. We combine the data collected from Drupal with the Apache server logs to allow for content analysis of data collected over 42 days. To allow botnets time to discover the honeypots, we activate the honeypots at least 6-weeks before data collection.

We generate three tables of content for each honeypot. In the user table, we record the information the spambot enters while registering and user login statistics that we summarize in Table 1. This includes the user id, username, password, date of registration, registration IP, and number of logins. In the content table, we record the content of spam posts and comments which we summarize in Table 2. This includes the blog node id, the author's unique id, the date posted, the number of hits, type of post, title of the post, text of the post, links in the post, language of the post, and a taxonomy of the post from the Alchemy API.

Honeypot	Quantity	Mean Logins/User	# of Countries
ggjx	62992	1.066	83
gjams	28230	1.102	40
npcagent	34332	1.05	53

Table 1: User table characteristics for three honeypots

Honeypot	Quantity	Avg. Hits	Avg. Links	English Posts
ggjx	2279	28.237	2.356	1962
gjams	2225	18.178	0.311	2137
npcagent	1430	29.043	1.823	1409

Table 2: Characteristics for the content tables

Honeypot	ggjx	gjams	npcagent
# Of Entities	3430	1790	1566
# of Users	62992	28230	34332
Mean Users/Entity	18.365	15.771	21.923
Max Users/Entity	37589	14249	23577
σ of Users/Entity	666.128	359.619	611.157
# of IPs	5291	3092	2120
Mean IPs/Entity	1.543	1.727	1.354
Maximum IPs/entity	118	135	60
σ of IP Quantity	4.277	5.551	2.406
Mean Posts/Entity	.664	1.243	.907
Max Posts/Entity	163	484	664
σ of Posts/Entity	5.319	14.448	17.256
% of Entities Who Posted	15.2	12.4	13.5

Table 3: Characteristics of entities

Lastly, in the access table, we include data and meta-data from the Apache logs. This includes the user id, the access IP, the URL, the HTTP request type, the node ID, and an action keyword describing the type of access.

Our honeypots received a total of 1.1 million requests for ggjx, 481 thousand requests for gjams, and 591 thousand requests for npcagent.

Entity Reduction

It is widely accepted that spambot networks, or botnets, are responsible for most spam. Therefore, we algorithmically reduce spam instances into unique entities representing botnets. For each entity, we define 4 attributes: entity id, associated IPs, usernames, and associated user ids. To construct entities we scan through the users and assign each one to an entity as follows.

1. For a user, if an entity exists which contains its username or IP, the user is added to the entity.
2. If more than one entity matches the above criteria, all matching entities are merged.
3. If no entity matches the above criteria, a new entity is created.

We summarize the entity characteristics in Table 3. The maximum number of users in one entity is almost 38 thousand for ggjx with over 100 unique IP addresses. These results confirm what is expected - the vast majority of bots interacting with our honeypots are part of large botnets. This also allows us to perform content analysis exploring what linguistic qualities differentiate botnets.

Feature	Description	Indicates	Effective
Bag or Words	Set of words with count	Lexical content	Yes
Alchemy	Document taxonomy	Taxonomy	Yes
Link	URL core domain names	URL similarity	Variable
Vocab	Vocab complexity	Vocabulary complexity	No
Part-of-speech	A BoW of parts-of-speech	Simple syntax	No

Table 4: NLP feature sets we consider for our content analysis and their effectiveness at differentiating botnets

Content Analysis

To better understand botnets, we use natural language processing (NLP) (Collobert and Weston, 2008) for analyzing the linguistic content of entities. For our analysis, we consider various feature sets as proxies for linguistic characteristics as summarized in Table 4. We use a Maximum Entropy classifier to test which features differentiate botnets. In order to test a feature, we train the classifier with 70% of the posts, randomly selected, from the N largest entities and test it with the remaining 30% of the posts. Our final results are the average of three runs.

The first feature set we test is Bag Of Words (BoW) which models the lexical content of posts. Put simply, each word in a document is put into a 'bag' and the syntactic structure is discarded. For implementation details, see our technical report. In figure 2, we show our analysis of the BoW feature set.

When considering the top 5 contributing entities, the classification accuracy is less than 95% which implies that the lexical content of botnets varies greatly. The second feature we consider, is the taxonomy provided by IBM

Watson's AlchemyAPI [4]. Alchemy's output is a list of taxonomy labels and associated confidences. For the purpose of our analysis, we discard any low or non-confident labels. In Figure 3, we show our analysis of the Alchemy Taxonomy feature set which highlights the accuracy of Alchemy's taxonomy. We note that the Alchemy Taxonomy feature set is dramatically smaller in size than the BoW feature set while still providing high performance. This indicates a full lexical analysis is not necessary but a taxonomic approach is sufficient. Our third feature is based on the links in the posts. To create the feature, we parse each post for any HTTP links and strip the link to its core domain name.

The classifier with the link feature set had varied results, as shown in Table 5, where it was reliable in differentiating ggjx entities but less reliable for the other two honeypots. These results correlate with link scarcity from Table 2.

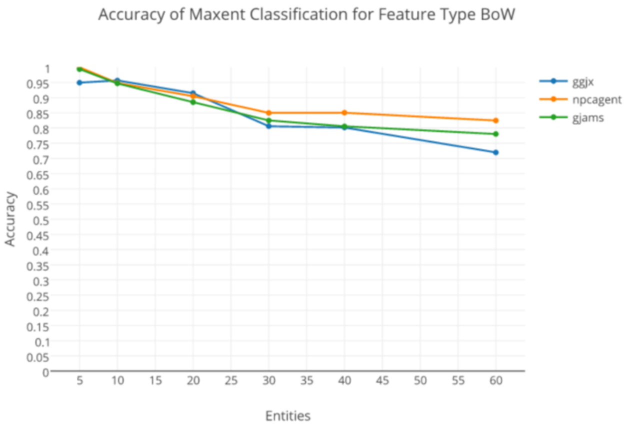

Figure 2

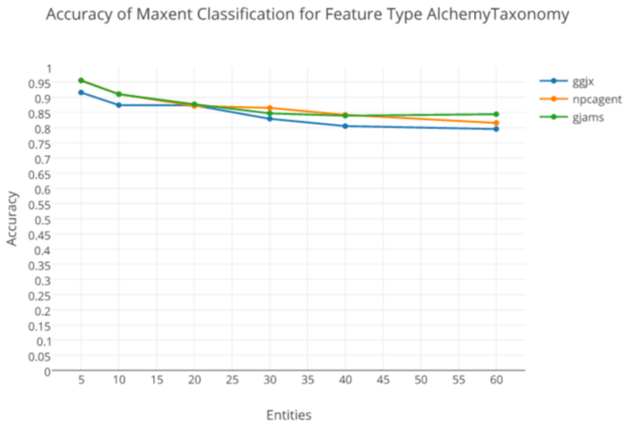

Figure 3

We test the normalized vocabulary size of a post as a feature. We derive this from the number of unique words divided by the total number of words in the post. As shown in Table 5, the vocabulary size does not differentiate botnets.

We also form a feature set based on the part-of-speech (PoS) makeup of a post using the Stanford PoS Tagger. The Stanford PoS tagger returns a pair for each word in the text, the original word and corresponding PoS. We create a BoW from this response that creates an abstract representation of the document's syntax. As shown in Table 5, the PoS does not differentiate botnets.

Feature Set	Database	Accuracy (10 entities)	Accuracy (60 entities)
BoW	ggjx	93%	71%
BoW	gjams	92%	78%
BoW	npcagent	93%	83%
Alchemy	ggjx	87%	80%
Alchemy	gjams	91%	84%
Alchemy	npcagent	91%	82%
Link	ggjx	89%	84%
Link	gjams	53%	37%
Link	npcagent	72%	61%
PoS	ggjx	32%	16%
PoS	gjams	53%	39%
PoS	npcagent	70%	60%
Vocab	ggjx	32%	17%
Vocab	gjams	50%	36%
Vocab	npcagent	74%	60%

Table 5: Accuracies for various features when identifying 10 and 60 entities using the maximum entropy classifier

Conclusions

In this paper, we examine interesting characteristics of spam-generating botnets and release a novel corpus to the community. We find that hundreds of thousands of fake users are created by a small set of botnets and much fewer numbers of them actually post spam. The spam that is posted is highly correlated by subject language to the point where botnets labeled by their network behavior are to a large degree re-discoverable using content classification (Figure 3).

While link and vocabulary analysis can be good differentiators of these botnets, it is the content labeling (provided by Alchemy) that is the best indicator. Our experiment only spans 42 days, thus it's possible the subject specialization is a feature of the campaign rather than the botnet itself.

Introduction

In the scholarly domain, annotation is a fundamental activity (Unsworth, 2000). Current web-based annotation facilities enable a specific way of annotation (via note-taking, highlighting or commenting) which are useful when scholars are exploring or gathering an initial set of resources, but more sophisticated support is needed for detailed analysis, close reading, and data enrichment. At this point, it is important to take into account the structural relations between documents and their parts. For example, when annotating a letter, annotation tools should be aware that a targeted text fragment is the name of the sender, or that the annotation of a film targets the intellectual work instead of the specific version or copy on which the annotation is made.

In addition, many standalone tools use annotation models with idiosyncratic solutions to enable the relations between different media objects and their parts, which limits the possibilities to exchange those annotations . In general, there is a lack of necessary details for durable access to and interpretation of annotations. For this, detailed information is needed about the annotated object, the annotator and the annotation itself (Melgar et al. 2016, Walkowski & Barker, 2010). In this paper we focus on the requirements for the annotated object, in a web-based environment, and propose a method for making necessary details of objects openly available for any annotation tool.

Requirements of scholarly annotation

In line with (W3C 2017b) we refer to the object that is annotated as the annotation target, the content of the annotation as the annotation body and who or what creates the annotation as the annotation creator. All three are complex entities with aspects that have consequences for interpreting an annotation (Melgar et al., 2016).

Annotation Creator: With respect to the creator it is important to know the intention/motivation for making the annotation (Walkowski & Barker, 2010) and when sharing and reusing annotations, their level of expertise, both in terms of the scholarly domain and in the nature of the annotation task (e.g. the amount of experience/expertise of the annotator in classifying objects according to a controlled vocabulary).

Annotation target: of the target it is important to know which part of the object is targeted. This is not merely about addressing media fragments. Media (e.g., html, mp3, jpg) are carriers of abstract information objects (scenes in movies, chapters in books, objects in pictures) with different conceptual levels (e.g. work, expression or manifestation , see Figure 1) and it is essential to be able to address those abstract objects and the relationships between them.

Annotation body: Of the content of the annotation it is important to know its nature (a natural language comment, structural or subject metadata, a link to another resource), in what form it is made (e.g. closed representation or natural language representation), at what level of control (from mostly uncontrolled to strictly controlled and structured) and for what scholarly purpose, e.g. gathering or exploring sources or thematic or stylistic analysis (Melgar et al., 2017).

State of the Art

There are various models for capturing digital annotations to make them accessible and interpretable. The Web Annotation Data Model (W3C 2017a, 2017b) is a generic model that covers aspects of the annotation body, target and creator. This model focuses on annotations in the context of online social interaction (e.g., commenting, sharing), not necessarily on scholarly annotations done during analysis or data enrichment .

An extended model specifically for scholarly research was proposed by Hunter et al. (2011), which includes context aspects for both the annotation body and target. The Annotating All Knowledge Coalition is also directed at scholarly annotation and lists several issues, including:

1. The lack of support for discovery, sharing and reuse of annotations.
2. Underutilization of collections.
3. The closed and non-standardized nature of current annotation tools.

Current annotation support is either part of a suite of functionalities in monolithic applications with their own models for annotation (e.g. TextGrid , Textual Communities , eLaborate , CATMA for text,Elan and Anvil for multimedia materials, and QDA software packages for mixed media qualitative data analysis), or they lack specificity in describing the annotation target, e.g. Hypothes.is (Perkel, 2015) and Pundit (Grassi et al., 2012) and site-specific annotation tools, e.g. in The Diary of Samuel Pepys).

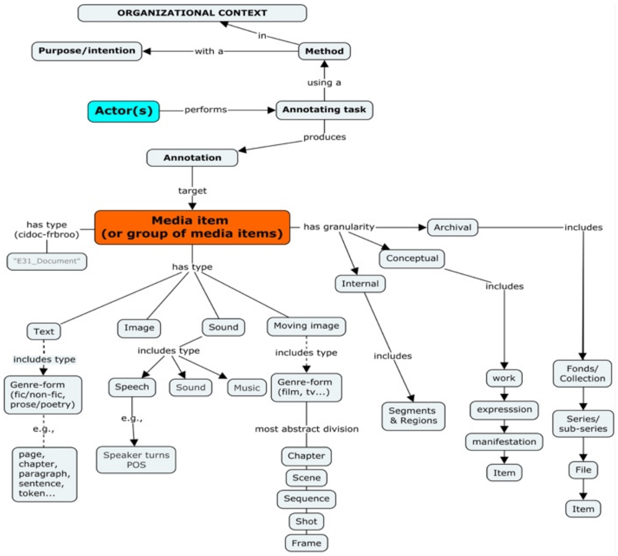

Figure 1. Conceptual model of annotated object (details of other parts of the model are left out for clarity)

Building on earlier work (Melgar et al., 2016), in this paper we argue the need for application support for more specificity of the annotation target (see Figure 1). We identify two additional issues with the current state-of-the-art:

4. The W3C annotation protocol lacks support for a potential annotation target identifying and describing itself to the annotation tool.
5. The model also lacks a schema, which would allow scholars or website maintainers to define constraints for a specific class of annotations that is applicable in the context of a specific group of scholarly objects.

Use case: annotation in scholarly digital editions

These issues are illustrated by a scenario of a digital scholarly edition where scholars have a need for annotation support (Boot, 2009, Robinson, 2004, Siemens et al., 2012). Consider an edition that wants to incorporate an external annotation tool into its pages (Figure 2): an edition server shows an edition to a client in a browser. The annotation client runs within that same browser window, but doesn't know about the edition's structure and it talks with its own server. To communicate intelligently with the user, the annotation client needs information about the structure of the edition, which has to be provided by the edition.

The annotation tool should know about the edition's structure for a number of reasons:

- The edition often contains multiple representations of the same text fragment. There might be a diplomatic and a critical transcription, one or more translations, audio versions, and who knows what other versions, and annotations made in one of these should be available in others;
- Other sites may have other editions of this particular text. It should be possible to exchange annotations between them;
- The edition has an internal structure, e.g. a book divided in chapters, or the fragments appearing in modern authors' drafts, or the elaborate structure with multiple apparatuses of some editions of medieval texts. An annotation that refers to a specific component of an edition should be able to address that component and know what sort of component it is.
- The edition should be able to propose suitable annotation types for its components. For personal names, it might suggest an annotation type that links the person to an authority file. For transcriptions, there might be special annotation types for proposed corrections to the transcription. Edition collaboratories could use the annotation functionality to solicit multiple sorts of specialised information from its collaborators.

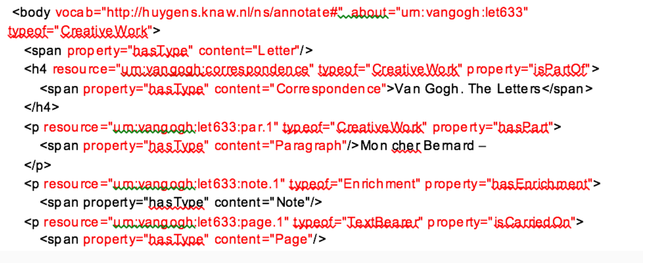
This proposal requires that: (i) the edition describes itself and its structure to the annotation tool, and provides suitable labels for the annotatable objects; (ii) the edition can suggest annotation types for the annotatable objects;

(iii) the effort to integrate annotation functionality in existing editions is minimal; (iv) the annotation tool is generic, but able to handle the created annotations with awareness of the structure that they apply to (it can e.g. return aggregated annotations); (v) the annotation targets are durable and not formulated in terms of HTML structure; and (vi) URI's should be treated as opaque (i.e., we shouldn't try to guess the relations between the annotated components based on their URIs); and lastly (vii) URIs should be canonical.

Proposed Solution

We propose a solution similar to Schema.org (an initiative for adding structural semantics to information on the web) whereby descriptive information about annotatable resources is made accessible to the client by embedding it in the HTML presentation layer through RDFa attributes (Figure 3), using an extensible resource descriptive ontology. Figure 4 shows a basic ontology for text objects (left half of Figure 4) with an edition-specific extension for the example edition (right half of Figure 4). This ontology shares concepts with the FRBRoo ontology (Bekiari et al., 2015) but starts from specific annotation-related concepts. In future work we will investigate extending the ontology with FRBRoo concepts.

Although this approach is focused on annotation of resources on the web, the same principle could be applied in offline annotation, if the offline resources are described in a similar way and annotation clients are developed to make use of this. Also, descriptive information for textual sources can be embedded as markup, but for audiovisual documents, this has to be done via a separate representation, for instance using SMIL (Bulterman et al., 2008).



```
<body vocab="http://huygens.knaw.nl/ns/annotate#" about="urn:vangogh:let633"
typeof="CreativeWork">
   <span property="hasType" content="Letter"/>
   <h4 resource="urn:vangogh:correspondence" typeof="CreativeWork" property="isPartOf">
      <span property="hasType" content="Correspondence">Van Gogh. The Letters</span>
   </h4>
   <p resource="urn:vangogh:let633:par.1" typeof="CreativeWork" property="hasPart">
      <span property="hasType" content="Paragraph"/>Mon cher Bernard –
   </p>
   <p resource="urn:vangogh:let633:note.1" typeof="Enrichment" property="hasEnrichment">
      <span property="hasType" content="Note"/>
   <p resource="urn:vangogh:let633:page.1" typeof="TextBearer" property="isCarriedOn">
      <span property="hasType" content="Page"/>
```

Figure 3. HTML fragments of a letter of Vincent van Gogh (http://vangoghletters.org/orig/let633) described by embedded RDFa. The letter is identified by a URN (urn:vangogh:let633) and defined as a CreativeWork. It is part of a larger CreativeWork, Van Go

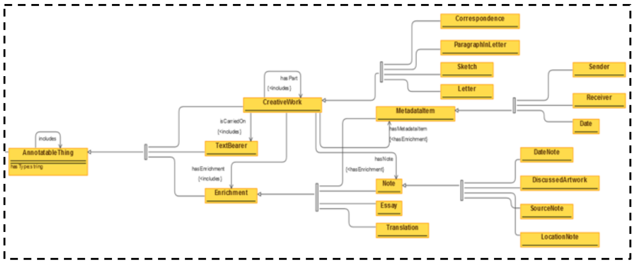


Figure 4. Basic ontology for text objects (left of dashed line) and extended ontology for Van Gogh Letters Collection (right of dashed line). The basic ontology recognizes three types of annotatable things: the creative work being edited and its parts (also creative works), the text bearers (e.g. manuscript pages), and editorial enrichment of any sort. Projects can create an extended ontology to suit their needs. The extended ontology shown here creates specialized classes for the needs of the Van Gogh letter edition (http://vangoghletters.org/).

Methodological impact

In our proposal annotatable resources describe their own semantic structure, thereby facilitating fine-grained annotations. With the RDFa attributes, annotation clients can identify the annotation target in terms of the resource structure (issue 4), which makes annotations less dependent on specific views on the underlying object. Furthermore, this allows development of lightweight open source annotation clients that web services can easily embed to bring annotation to collections of scholarly interest (issue 3).

This makes it easier for scholars to use and reuse annotations to support the argument made in a scholarly article (issue 1). It allows distinguishing different groups of annotations, so researchers can choose to display certain groups of annotations, thereby avoiding being drowned by irrelevant annotations (issue 5). It facilitates employing annotation functionality to ask for targeted comments on resource parts (what do you think of this translation? What clarification of this material are you missing?). Scholars can also more meaningfully combine and compare them across collections and media types, e.g. analyse the correspondence between book and film versions of an intellectual work (issue 2).

If the annotations are consistently stored using open protocols, it becomes possible to reference them in scholarly publications. Collateral benefit of floating this form of 'deep web' semantics to the surface is that other external services such as search engines can also use the exposed semantic information to reason about available resources.

University–Community Digitization Partnerships: Accessing Trans Collections in LGBT Community Archives

Elspeth Brown
elspeth.brown@utoronto.ca
University of Toronto, Canada

Cait McKinney
cait.mckinney@utoronto.ca
University of Toronto, Canada

This paper explores university and community partnerships to preserve and provide online access to LGBTQ cultural heritage materials, focusing in particular on projects that improve the accessibility and profile of transgender materials in traditional gay and lesbian organizations. The paper reflects on the promises and challenges of pursuing trans-positive, activist digital humanities projects within the context of a historically cis gay and lesbian analogue archive. How have anxieties surrounding digital transformations in the archive become enmeshed in concerns about changing understandings of sexual and gender embodiment within the LGBTQ community? How has the queer archive's shift to the digital engendered not only "privacy anxieties" (Chenier 2015) but also identity anxieties, as a new generation of non-binary and trans volunteers, scholars, and activists reshape the meanings of "LGBTQ" within the community archive?

The paper reports on the first three years of the LGBTQ Oral History Digital Collaboratory, a five-year SSHRC-funded project directed by Elspeth Brown at the University of Toronto. The Collaboratory works in partnership with the Canadian Lesbian and Gay Archives, a volunteer-run, community archives, to design and implement in-house digitization programs. This project has invested significant labour and technology into the acquisition and digitization of transgender materials under-represented in the CLGA's collection, and in historically "Gay and Lesbian" community archives more broadly (Rawson 2009; Morris and Rawson, 2013).

This paper will outline the technical and political concerns behind two Collaboratory/CLGA partnership projects aimed at improving access to trans materials: 1) The development of an audio digitization station for oral history cassette tapes; and 2) the processing and digitization of transsexual artist and activist Mirha-Soleil Ross' personal papers. We argue that the planning and implementation of digitization initiatives is a significant catalyst for broader, mandate-driven shifts within LGBTQ cultural heritage organizations. We argue that this is particularly the case when these partnerships drawn on humanities-based approaches that understand the archive as a worlding technology (Stoler 2010, Eichhorn 2013) caught up within broader conflicts that challenge and divide LGBT spaces. More specifically, the paper outlines how university partners can support the development of digital infrastructures in community-based, volunteer-engaged contexts. We suggest that this labour can be understood as part of a broader politics of digitization that must be approached with care when forming community partnerships. We understand digitization as a wide-ranging process that transcends the conversion of "analog" materials into digital formats: digitization has the potential to shift economies of attention in social movement organizations undergoing transition (McKinney 2015).

Theoretically, the paper engages with queer, trans, and feminist approaches to digital archives (Chenier 2009; McLeod et al, 2014; Matte 2015). In particular, we draw on scholarship that has considered how trans materials have the potential to confound, challenge, and ultimately re-formulate archival systems (Brown 2015; Roberto 2011). Here, digital spaces and technologies provide historical "worldmaking" opportunities often denied to trans histories within "LGBT" spaces (Rawson 2014). Emphasizing the relationship between "trans" and movement (Stryker, Currah, Moore 2008), we consider the moments where digitization meets trans as potentially productive but also acrimonious challenges for LGBT archives primarily concerned, in practice, with GayandLesbian (Noble 2006) cultural memory.

The paper covers two case studies from the Collaboratory/CLGA project, and will explain the technical questions and organizational concerns behind the design and roll-out of both projects in order to support the argument outlined above.

Audio Digitization Station

Begun in year one (2014), this station sought to develop a technologically accessible digitization solution for audio-cassette tapes, most of which contain oral histories produced in the 1980s and 90s. We will outline the accessibility concerns at the heart of this project, including how the audio digitization protocol the project established sought to build organizational comfort with digitization practices by integrating the system with existing database infrastructures and ways of organizing volunteer labour at the archives. This part of the paper will also address how the Collaboratory identified trans audio collections within the archives, and will touch on some of the challenges in locating these materials. This material will be useful for humanities scholars in sexuality and gender studies who are concerned about creating digital preservation plans for audio-based primary source materials they might collect or create.

Mirha-Soleil Ross Papers

Begun in year three (2016), this project is working to process, digitize, and improve access to the personal papers of Mirha-Soleil Ross, one of the most significant figures in transgender activism and cultural production in Canada. Donated to the archives in 2008, this large collection had not yet been processed by archives volunteers and as result, was mostly inaccessible to researchers. We are working in collaboration with Ms. Ross, and several members of the trans community, to organize these materials, determine access restrictions for sensitive content, create an online finding aid, and an online digital collection using the Omeka platform, which will sample from the larger volume of material. This part of the paper asks how digitization might provide an opportunity to repair damaged relationships between LGBT organizations and trans communities. It also considers some of the unique privacy concerns scholars must consider when providing online access to materials that document trans lives.

Introduction

Cultural diversity has been an increasing source of debate within the digital humanities community. The concentration within the *Debates in Digital Humanities* series (Gold, 2012; Gold and Klein, 2016) of pieces reflecting the increasing prominence of matters related to race, gender, cultural diversity and difference is but one marker of the extent to which diversity matters. The Orlando Project in feminist literary history incorporated an intersectional understanding of identity categories from the outset (Brown, Clements and Grundy, 2006-2017). Translating Orlando's Extensible Markup Language (XML) data into linked open data (LOD) to make it accessible, interoperable, and amenable to a range of analytical approaches (Simpson and Brown) requires an ontology that will serve both Orlando and the broader research community hosted by the Canadian Writing Research Collaboratory (CWRC). This paper outlines the CWRC ontology design and the challenges of shifting from semi-structured to structured data (Smith, 2016: 273).

Much work on digital diversity expresses skepticism of the ability of systematized knowledge structures to capture the performative, processual, and contingent nature of lived subjectivities. Tara McPherson (2012) stresses that "computers are themselves encoders of culture" and calls for more attention to be paid to the interconnectedness of the structures of code and the management of race socially: "Just as the relational database works by normalizing data—that is, by stripping it of meaningful, idiosyncratic context, creating a system of interchangeable equivalencies—our own scholarly practices tend to exist in relatively hermetically sealed boxes or nodes." Scholars including Lisa Nakamura (2002: 120) and Moya Bailey (2011) see value in "messiness" as a way to push against and redefine the contours of a digital humanities scholarship that remains rooted in predominantly white epistemology.

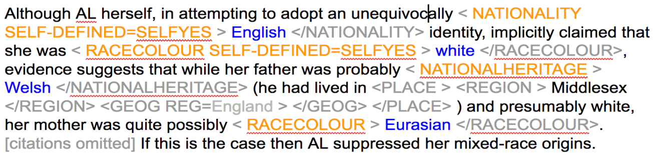
At the same time, relegating representations of difference to narrative rather than structured data will produce gaps within big data that are both impoverishing for humanities inquiry and dangerous in their political implications (Lerman, 2013; Trevinarus, 2014; "Use"; Brown and Simpson, 2013). Adriel Dean-Hall and Robert Warren (2013) have advocated approaches that respect the privacy and preferences of lived human subjects while improving the responsiveness of online systems to diversity and complexity. Within a LOD context, what are finally findable, processable, and reusable on the global graph are things, not strings, so the challenge is the extent to which nuance, context, and indeed messiness can be incorporated into a LOD ontology.

The Orlando Project (Brown, et al., 2006-2017) charted a middle ground between narrative and structure with its bespoke XML tagset. The team struggled with the hierarchical nature of XML, particularly in relation to identity categories, torn between knowledge that readers would turn to Orlando to find writers associated with particular cultural identities and recognition that such categories are discursive rather than essential (Fuss, 2013). We devised a "Cultural Formation" tagset to depict identity as neither unitary nor immutable, and as much related to representational acts as to the lived experiences into which those representations blur. Precisely because constituted through discursive and social practices, vocabularies associated with subjectivities and identities can shift over time and place, and throughout an individual's lifetime.

Cultural formation tagset

The Cultural Formation (CF) tagset recognizes categorization as endemic to social experience, while incorporating variation in terminology and contextualization of identity categories by employing tags at different discursive levels. CF tags describe the subject positions of individuals through 1) contextual tags that encode substantial discussions: class; language; nationality; race and ethnicity; religion; and sexuality; and 2) granular tags that describe, in a word or short phrase, class; ethnicity; gender; geographical heritage; language; nationality; national heritage; political affiliation; race or colour; religious denomination, and sexual identity. With the exception of gender and social class, the Orlando schema eschewed fixed attribute values for the granular tags, allowing the prose to employ the most appropriate language for the context. The structure was not entirely logical or parallel, and we are making the ontology more consistent. The granular tags possess attributes regarding forebears and whether a subject self-identified with a particular term. The tagset aimed to highlight the extent to which social classification is culturally produced and discursively embedded. Rather than disambiguating leaky cultural categories, the team considered them as mutually constitutive with historically specific discursive frameworks, including our tagging structures.

CF encoding pointed users towards a framework for raising and debating complex matters for cultural investigation rather than standardized classifications, refusing to neatly group writers into distinct and fixed categories, since those categories were neither stable nor mutually exclusive (Algee-Hewitt, Porter, Walser, forthcoming). The coding structure can represent quite complex identities, as in the case of Anna Leonowens, the writer whose story of life as governess to the royal Siamese harem was popularized in *The King and I.* Partial markup for the first paragraph of her CF description is shown in Figure 1.



Although AL herself, in attempting to adopt an unequivocally < NATIONALITY SELF-DEFINED=SELFYES > English </NATIONALITY> identity, implicitly claimed that she was < RACECOLOUR SELF-DEFINED=SELFYES > white </RACECOLOUR>, evidence suggests that while her father was probably < NATIONALHERITAGE > Welsh </NATIONALHERITAGE> (he had lived in <PLACE > <REGION > Middlesex </REGION> <GEOG REG=England > </GEOG> </PLACE>) and presumably white, her mother was quite possibly < RACECOLOUR > Eurasian </RACECOLOUR>. [citations omitted] If this is the case then AL suppressed her mixed-race origins.

Figure 1: Adapted from Brown, Clements and Grundy, “Anna Leonowens”, Life tab, Show Markup option

The CF component of Orlando’s knowledge representation is thus crucial to its intersectional approach to identity (Brown et al., 2006). Creating a LOD ontology that was not self-referential, however, requires translating the strings or literal values from CF tags, to link Orlando’s semantic structures to other semantic web communities.

LOD ontology creation

An ontology “is a formal naming and definition of the types, properties, and interrelationships of the entities that really or fundamentally exist for a particular domain of discourse” (Wikipedia, Ontology - Information Science). Using a standard ontology language such as OWL allows others to interact and exchange with a particular view of the world through a computational process of mediation. As a representation of that understanding, an ontology can be referenced, (dis)agreed with, extended, and used operationally. The coexistence of different representations provides the foundation for translations between LOD concepts.

Ontology creation in our case, as in many others, was driven by the idiosyncrasies and limitations of an existing data set. The information architectures of application databases or XML stores are not always reconcilable to a consistent information system. The CF tagset represents a major challenge in that its structure was designed to eschew disambiguation. Even the major tags were difficult to relate within a concise ontology (Figure 2).

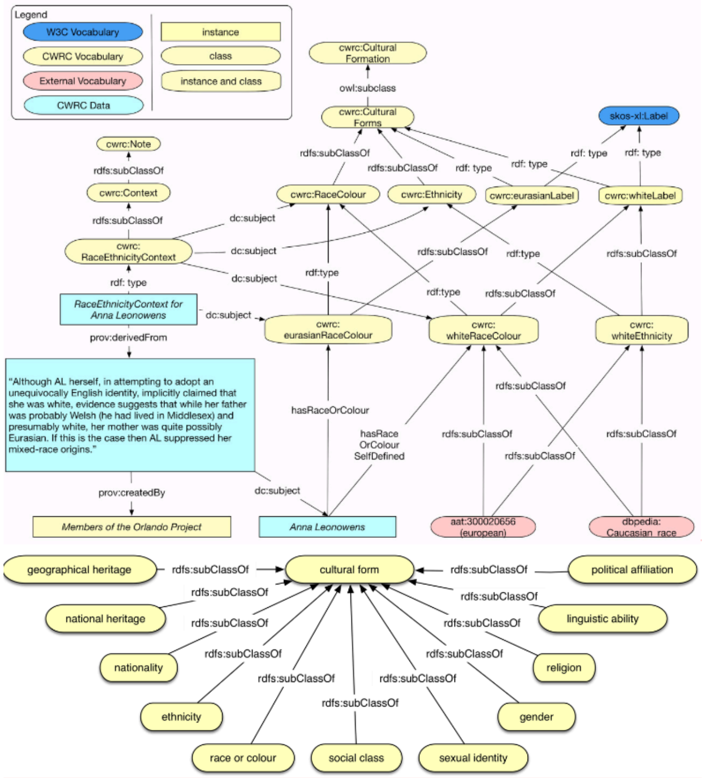


Figure 2: Schematic representation of the granular Cultural Formation tags from Orlando (Please note that these representations are simplified in order to make them legible to the reader.)

For example, nationality and national heritage are not employed as commensurate with citizenship, a well-defined legal concept related to an organized state. They can also be related to a geographical area, which may or may not coincide with a state. Finally, nationhood can reference socio-political constructs such as Lesbian Nation (Johnston, 1973; Ross, 1995; Munt,1998) or disavowals of nationality such as Virginia Woolf’s (1938: 197), which Orlando quotes alongside assigning Woolf an English nationality, a contradiction that requires contextual evidence to make sense.

Linked into context

We decided to make all human-readable annotations within the dataset instances of contextual notes to which the ontological classes are directly tied (Figure 3).

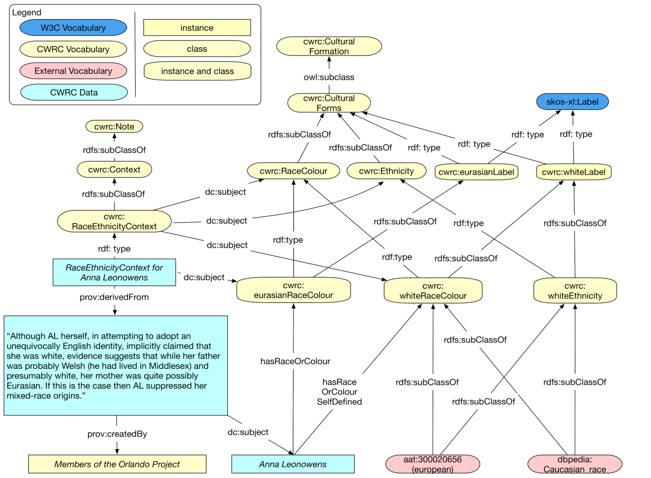

Figure 3: Schematic representation of how the discursive context (note) links to the classificatory structure, and how classificatory labels relate to predicates and external ontologies. Skos:narrower/broader relationships are also used, but omitted here to improve legibility

Thus we model the discursive context within a Race[or]EthnicityContext class. The note instance links to instances of granular category labels, here RaceColour; it provides the provenance and the basis for links to source information. Linking to the provenance of the LOD is particularly important for disputed or contradictory information, as in our example. We are modeling the original Orlando narrative as a source document for our LOD provenance using the the Web Annotation Data Model's subproperty instances. We aim to link every triple to the prose from which it is derived, providing provenance information and contains citations to the sources on which identity assertions are based.

Relating cultural formations

Cultural formation for Orlando is understood primarily as representational, which is not to say that cultural formation is not real or that it has no material effects. The complex signifiers of cultural identities float across Orlando tags as cdata or free text in a semi-structured representation of cultural identities and categories. For the CWRC ontology, we strategized to relate this ontological perspective to that of external vocabularies without conflating our truth with theirs. Our architecture does not import other ontologies wholesale, but adopts components of major vocabularies such as BIBO, FOAF, and FRBR, and relates to large vocabularies in defined ways. As indicated in Figure 3, the instances of cwrc:whiteRaceColour and cwrc:whiteEthnicity within the CWRC ontology are subclasses of the cwrc:whiteLabel. This retains the ambiguity of terms such as “ white” or “ Jewish” precisely as labels that draw together particular types of identity categories, as well as subClasses of those labels. As indicated, those subClasses can be linked to terms in external vocabularies, but both internal and external terms are understood within the CWRC ontology as labels. Indeed, constructing this ontology has brought home to us the need for the LOD community to think through with greater care the relationship between representation and “ reality” in LOD ontologies. A further complication is that identity categories are not only historically contingent but often also change over a particular individual's lifetime. The Orlando dataset supports such nuance in only a few cases, so we have not started with this gnarly problem, but we aim to build into the ontology the capacity to represent such cultural formation dynamics in order to accommodate more temporally precise data.

Conclusion

The CWRC ontology design avoids representing RDF extractions from Orlando data as positivist assertions, and yet produces machine-readable OWL/RDF-compliant graph structures. The ontology allows references to, without endorsing, external ontological vocabularies that are nevertheless part of documenting intersectional cultural processes and identities.

We will present the CWRC ontology as built around the CF design described here, and we will demonstrate its implications through several practical examples. Figure 4 shows schematically the intersectionality of multiple identity categories associated with Leonowens, including the ways that instances are related by subclass relationships in accordance with OWL principles. This importantly allows us to reference components of other ontologies (here the Muninn Appearances ontology, Library of Congress Subject Headings, Getty Art and Architecture Thesaurus, and DBpedia) without adopting them wholesale.

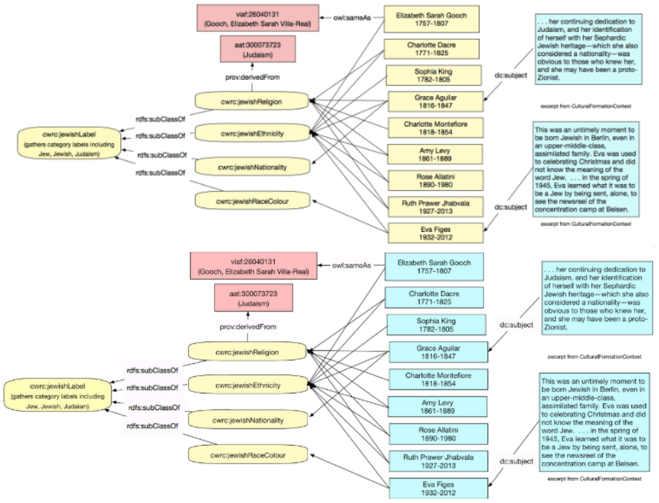
Figure 4: Cultural Formation triples related to Anna Leonowens, with corresponding XML-encoded context notes

Figure 5 indicates the ability to see patterns and outliers related to different categorizations of Jewishness in a small subset of Orlando authors.



. . . her continuing dedication to Judaism, and her identification of herself with her Sephardic Jewish heritage—which she also considered a nationality—was obvious to those who knew her, and she may have been a proto-Zionist.

This was an untimely moment to be born Jewish in Berlin, even in an upper-middle-class, assimilated family. Eva was used to celebrating Christmas and did not know the meaning of the word Jew. . . . in the spring of 1945, Eva learned what it was to be a Jew by being sent, alone, to see the newsreel of the concentration camp at Belsen.

Figure 5: Subset of CF triples related to a subset of writers, with sample context annotations and external links; predicates linking individuals to subclasses are inferred (e.g. the edge between Elizabeth Sarah Gooch and cwrc:jewishReligion is hasReligion)

The ontology thus makes all specific instances of Jewishness as religion, ethnicity and so on subclasses of the label for Jewishness that groups them and highlights the extent to which the signifier Jewish is embedded in discourse. Our live presentation will demonstrate the ontology in action using the interactive HuViz (Humanities Visualizer) interface with a larger dataset. This dataset will contain a wider range of identity categories than we have been able to lay out in the diagrams here, and show the interaction between the ontology terms and the representations of individuals.

The Course of Emotion in Three Centuries of German Text— A Methodological Framework

Introduction

Texts not only carry factual, but also affective information, such as expressions of joy or grief. In the humanities, especially literary studies, emotion expression and elicitation (often in texts from prior language stages) have been focused on in many contributions (see, e.g., Carroll and Gibson (2011), Poppe (2012), Hillebrand (2011)).

Similarly, in natural language processing (NLP), emotion analytics have developed into an active area of research (Liu, 2015). Nevertheless, there is little previous work explicitly addressing emotion in historical language and the specific methodological problems this raises. Hamilton et al. (2016) as well as Cook and Stevenson (2010) presented methods for identifying amelioration and pejoration of words. Acerbi et al. (2013) and Bentley et al. (2014) demonstrated the potential of emotion analysis for the Digital Humanities (DH) by linking temporal emotion patterns in texts to major sociopolitical events and trends in the 20th century.

Our work goes beyond these studies in two ways: we claim to be more adequate as we combine these two approaches to analyze non-contemporary **text** based on time-specific **lexical** resources. We also claim to be more informative as we employ the Valence-Arousal-Dominance (VAD) model of emotion (Bradley and Lang, 1994) instead of simple **polarity** (positiveness/negativeness) alone. We have already shown the latter to be beneficial in DH applications (Buechel et al., 2016a). We hope that our work will be a step towards a new set of tools especially beneficial for areas such as literary studies (e.g., in distant reading (Moretti, 2013)) or history of mind.

Methods

The VAD model of emotion assumes that affective states can be described relative to three emotional **dimensions**, i.e., Valence (corresponding to the concept of polarity, see above), Arousal (the degree of excitement or calmness) and Dominance (feeling in or out of control of a social situation). The VAD dimensions allow for a more fine-grained modeling than polarity alone, e.g., words like *orgasm* and *relaxed* have similar Valence but opposing Arousal values (Bradley and Lang, 1999). Formally, the VAD model constitutes a three-dimensional vector space illustrated by Figure 1 (Buechel and Hahn, 2016).

The association of words with a VAD score is captured in **emotion lexicons**. These can either be empirically determined by aggregating subjective judgments of several human subjects; or they can be semi-automatically constructed allowing for greater size but reducing accuracy on individual words. For the semi-automatic construction, the typical approach is to expand an existing lexicon (the **seed lexicon**) based on word similarity (see below). There are several competing expansion algorithms. Cook and Stevenson (2010) were the first to describe expansion algorithms for the induction of the emotion value of words for non-contemporary language stages by using word similarity values determined from historical corpora.

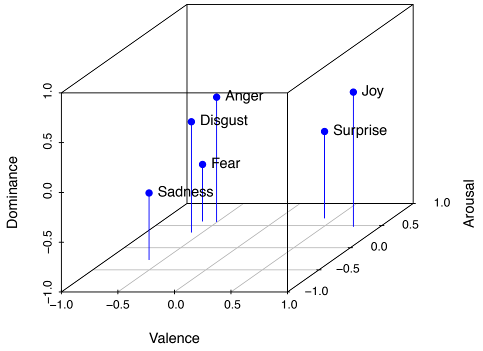

Figure 1: The VAD vector space. For ease of understanding, the positions of six *Basic Emotions* (Ekman, 1992) are given.

Extending this approach, we compared several emotion induction algorithms, viz., those by Turney and Littman

(2003), Hamilton et al. (2016), and Bestgen (2008). The former two were slightly modified to make them deal with numerical input values (for a more detailed description of these methods, see Buechel et al. (2016b) and Hamilton et al. (2016)).

We used point-wise mutual information with singular value decomposition (Levy et al, 2015; SVD$_{\mathrm{PPMI}}$) to measure word similarity, since it turned out to be superior for DH applications in previous work (Hellrich and Hahn, 2016). We used the German ANGST lexicon (Schmidtke et al., 2014) as seed. The individual algorithms were evaluated by comparing our induced historical lexicons against judgments of knowledgeable PhD students from the humanities. For this task, we asked them to make their assessments **as if** they were contemporary readers from the respective time period. The Turney-Littman algorithm performed best in this set-up and was thus employed for all subsequent analyses.

Experiments

For demonstration purposes, we here apply our methodology to the core corpus of the *Deutsches Textarchiv* (DTA; Geyken, 2013, TCF version from May 11, 2016) [German Text Archive], a well-curated and balanced collection of historical German texts. We analyzed texts created between 1690 and 1899, splitting the resulting corpus into seven slices (each spanning 30 years) to achieve similarly sized and sufficiently large subcorpora for further processing. We computed word similarities within each of these slices and then applied the Turney-Littman expansion algorithm, thus creating seven distinct emotion lexicons, each describing the emotion of words for its specific period. Given these temporally stratified lexicons, we claim that shifts in emotion association of words can be traced over time by comparing the emotion values a word exhibits in different lexicons. To validate this claim, we selected the words for which we could compute similarity scores in each time step (as these methods are more accurate for high-frequency words, rare words were excluded from our study) and standardized their VAD values for each lexicon and dimension (VAD).

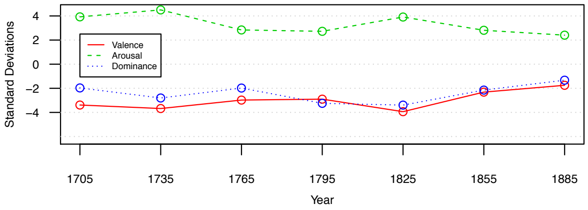

Figure 2: Development of the lexical item *Sünde* [sin] during the study period relative to the VAD dimensions.

Rank	Lemma and Translation			
	1690s		1890s	
1	todt-	(German prefix for 'death' as in 'deadly sins')	Lamm	lamb
2	Erzürnung	infuriation	hinwegnehmen	to take away
3	läßlich	minor (clerical)	Verzeihung	forgiveness
4	beichten	to confess	Ausschweifung	excess
5	Nachlaß	abatement/ inheritance	Gotte	god
6	Grobheit	crudeness	Schande	shame
7	verschweigen	to conceal	Reue	repentance
8	beweinen	to beweep	Ärgernis	nuisance
9	pichen	to pitch	Laster	vice
10	beichten	to confess	aufrichtig	sincere

Table 1: Top ten collocations of the lexical item *Sünde* [sin] in the DTA corpus comparing the 1690s and the 1890s using pointwise mutual information for scoring. Source: http://kaskade.dwds.de/dstar/dta/diacollo/

We illustrate this approach with an example from Figure 2. It displays an overall amelioration of *Sünde* [sin] whose onset roughly coincides with the age of enlightenment—often understood as the starting point of secularization (Sheehan, 2003), although care must be taken when interpreting these word course graphs since noise can be introduced from various sources (such as word similarity and emotion induction algorithms); both strongly depend on the amount of data available for each time step. This observation is in line with well-known findings from descriptive lexicography (Grimm and Grimm, 1942). The same semantic shift can also be discovered by a more established method, namely collocation analysis.

Table 1 reveals that *Sünde,* at the end of our examination period, has acquired an additional moral-bourgeois meaning facet (implied, e.g., by *Ausschweifung* [excess], *Ärgernis* [nuisance] and *Laster* [vice]) which was not present in the beginning. There, only the religious sense is traceable.

Going one step further, we then used these lexicons to examine how emotion is distributed over literary texts in the DTA in the course of time. We employed the *Jena Emotion Analysis System* (JEMAS; Buechel and Hahn, 2016), an open-source tool for emotion measurement using a configurable VAD lexicon. We processed each DTA text with the period-aligned lexicon, leading to the main methodological contribution of our work: linking the research areas of automatically inducing historical **word** emotion (e.g., Hamilton et al., 2016) and emotion prediction in historical **text** (e.g., Acerbi et al., 2013).

We scaled the resulting emotion values within each VAD dimension tracing the development of the three principal literary forms—Narrative, Lyric, and Drama—in German literature between 1690 and 1899. For each of the seven 30-year periods (organized in rows), we created three scatterplots (one for each pair of the VAD dimensions; organized in columns) resulting in 21 plots in total (Figure 3). Each data point represents one text—color and shape represent membership to the respective form.

It is evident from the plots how the distinction of the individual forms increases and decreases in emotional terms in the course of time. This application differs from typical stylometric approaches since we employ emotional features instead of word counts. We find the most distinct emotional patterns between 1780 to 1809 (approximately covering the Weimar Classicism) and between 1870 to 1899 (covering the late German Realism). Drama displays consistently more Arousal than Lyric and Narrative since 1750, whereas Lyric seems to be the most positive class (Valence) expressing the least control (Dominance). Of course, the examination of the DTA offers many more intriguing findings, however, for brevity, we limit ourselves here to presenting examples.

Conclusion

In this contribution, we described a novel methodological framework for quantifying emotion in non-contemporary text. Applying this approach to a 210-years section of the German DTA corpus, we find clear emotional signals for temporally evolving distinctions between the principal literary forms, viz. Narrative, Lyric, and Drama. All resources and software we developed for this work are publicly available.

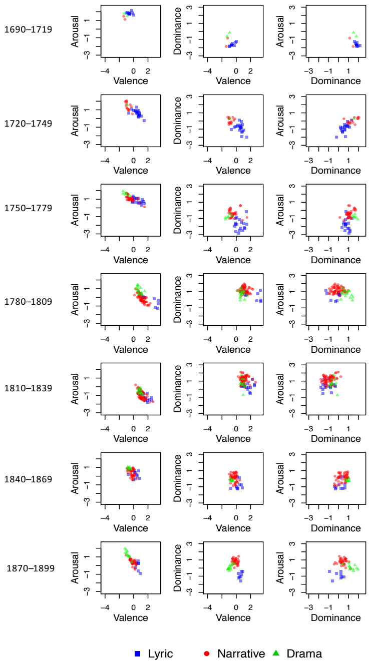

Figure 3: Distribution and development of the principal literary forms, Lyric (blue), Drama (green) and Narrative (red), relative to each pair of VAD emotions (in columns) between 1690 and 1899 (each row representing a 30-year slice).

Acknowledgments

This research was partially conducted within the Graduate School "The Romantic Model" supported by grant GRK 2041/1 from the Deutsche Forschungsgemeinschaft (DFG).

Introduction

In the mid 1990s, the Natural Language Processing Group at the University of Leipzig began work on the Wortschatz project which aims to provide corpora in hundreds of languages and in different size-normalisations, be that 100K, 300K or 1M sentences. As the resources grew in size, so did the number of requests for the data. In the early stages of the project a specific dump was created, parts of which even came with a small user-interface. The database dump was shared with interested researchers and partners in the business sector.

After some time, however, the personnel costs of this kind of collaboration became unsustainable. For this reason, a new plan was put into motion in 2004, consisting of the development of a SOAP-based API - the *Leipzig Linguistic Services* (LLS) - that enabled any interested person to access the data of the *Wortschatz* databases in any provided language (Quasthoff et al. 2006, Eckart et al. 2012). Overall 20 services were provided, delivering specific information such as baseform, category classifications, and thesaurus data. The aim of the LLS was to establish a *Service Oriented Architecture* (SOA) for linguistic resources based on small and atomic micro-services that could be combined by users for particular needs. Users were then not only able to browse through the *Wortschatz* website, but also to integrate those services with their own existing digital ecosystems.

In 2005 these services were made publicly available and by September 2006 all requests were systematically logged. In July 2014 the number of logged requests reached nearly one billion. While at the beginning the use was limited to academia, over time the services were increasingly used by the private and business sectors as well.

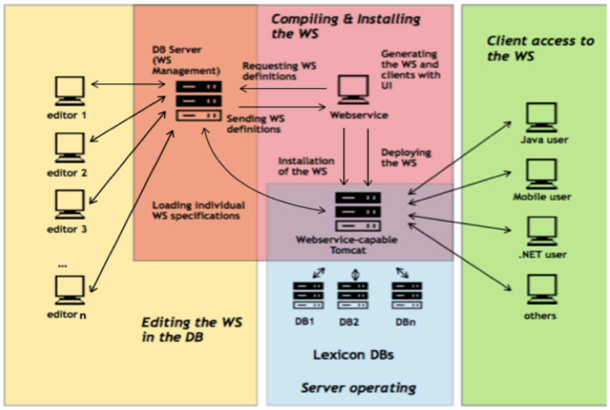

Figure 2. Four workflow modes separated by concern: editing (yellow); managing, compiling and deploying (red); hosting and operating (blue); using the LLS infrastructure (green).

The Leipzig Linguistic Services

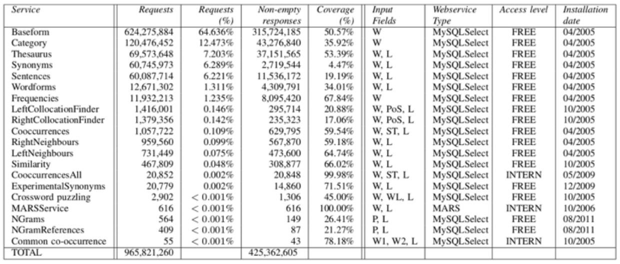
The intention of the overall LLS architecture was to be as simple and generic as possible. A generic architecture can be reused in different scenarios but tends to have too many parameters and options, while a simple architecture claims usability and guarantees a faster learning curve. In the following, we briefly describe the architecture of the LLS.

In order to create the server-side Java code for a specific webservice, a data-set needed to be added to the webservice management (yellow zone in figure 1). The necessary edits contain, besides others, information on the name and type of the webservice (see also table 1) or parameters. *Apache Ant* was used as the central tool for generating the back-end services and deploying them in a *Tomcat* server (see red zone in figure 1). The blue zone illustrates the operations of the *Wortschatz* databases. Using the generic description of the webservice in the WSDL-files a number of wrappers of generated source code were created and made publicly available by LLS users such as for C# as part of .NET, Perl, Python, Delphi, PHP, Ruby and JavaScript (see green zone in figure 1).

Independently from the underlying programming languages, over the past ten years we have observed different uses in research, business and in the private sector. In research, the LLS were used in the areas of text profiles and author classification (Borchardt 2005). The services were also used as data resources for sentiment analysis or for query expansion. Users from the business field were mainly interested in using *Baseform* or *Synonym* services for improving internal search indexes. The LLS data was also used for information retrieval tasks in portals for weighting words in a word cloud or to display enriching information. Private users accessed the LLS to complete crossword puzzles. A dedicated service was installed upon request just for this purpose (see also table 1), since it was possible to query a pattern of an incomplete word with a given word length limitation. From 2008 the SOA-based cyberinfrastructure of LLS was re-used in Digital Humanities projects such as eAQUA and eTRACES (Büchler et al. 2008).

Results

Table 1 provides an overview of the 20 services offered with a breakdown of the requests and the responses. Over half of the requests (*64.6%*) were made to the *Baseform* service. Similarly, services with high-quality and often manually-curated data, such as the *Thesaurus* and *Synonyms* services, were requested more often than the quantitatively-computed *Similarity* service, which provided similarly used words by assuming the distributional hypothesis (Harris 1954), and thus compared the co-occurrence vectors of two words. Even if the coverage for this service, *66.02%*, is significantly higher than, for example, the *Category* (*35.92%*) or the *Synonyms* (*4.47%*) services, users appeared to prefer precision over recall for their end-user applications.



Service	*Requests*	*Requests (%)*	*Non-empty responses*	*Coverage (%)*	*Input Fields*	*Webservice Type*	*Access level*	*Installation date*

Common co-occurrence	55	< 0.001%	43	78.18%	W1, W2, L	MySQLSelect	INTERN	10/2005
TOTAL	965,821,260		425,362,605					

Table 1. Overview of requests made to LLS between 2006-2014, in descending order. The Responses columns only list responses whose value was not empty. For space constraints, the values in the Input Fields column are abbreviated: Word (W.), Limit (L.), Pa

Low coverage is also caused by requests to German language databases, especially by compound nouns that cannot all be included in a *Baseform* or *Category* service. Many multi-word units (MWU) were also requested. Out of all the requests, *84,760,875* (*8.78%*) were MWUs. With regard to the distribution of the webservice usage, only the two most frequently requested services, *Baseform* and *Category*, were queried more often than the total count of the MWU requests. This speaks to the impact of MWUs.

The less frequently used webservices in table 1 were primarily limited to internal uses, to newly installed services or, as was the case for the Crossword Puzzling service, to manual usage instead of automatic bulk requests.
The following questions are discussed in the paper:

1. Geographical distribution and spread of requests
2. Requested languages distribution
3. Requests by cleanliness in terms of broken encodings or sending HTML code
4. Temporal distribution including lessons learnt from incompatibility issues of used software and their new versions causing a decrease in service usage
5. Identified service chains of the atomic LLS micro-services that users built on the client-side
6. Experiences for load balancing of linguistic services
7. Interoperability issues of programming languages and interpreting the WSDL-files differently
8. Comparisons of SOAP- and REST-based webservices

Conclusion

“If you build it, they will come“ is an infrastructure mantra that we can answer given the atomic micro-services of the LLS (more critical view by van Zundert 2012). However, with regard to easy-to-integrate and atomic micro-services we found that users were generally very pragmatic as they requested everything that they had found in texts or on webpages, such as RGB colour-sets, URLs and other meta-information. Based on the log-files, we conclude that it is easier to request a token and look for a match in the LLS database of millions of words rather than to invest only little time in conventional pre-processing and pre-selection on the client-side. Similarly, users repeatedly requested function words, sometimes only a few minutes apart. This user behaviour entailed a significant server load and user control over the requests. This type of recurring request on unchanged data could only be considered as spam.

We found that providing an infrastructure like the LLS over the course of a decade challenges the compatibility of used software components.

Moreover, from a Natural Language Processing (NLP) standpoint, the results contribute to existing conversations about the difficulty of building balanced and representative corpora. In fact, user interests detected in the LLS log-files can help to enrich corpora by adding further topics. The contribution also touches upon discussions about qualitative and manually-curated data versus automatically-computed and quantitatively-available results of language technology algorithms. Notwithstanding the improvement of NLP algorithms, our results show that users prefer qualitative data and that they often request these services even if the domain and concept coverage is relatively low. The conclusion we draw from the user behaviour observed in almost one billion requests is that research fields, including the Digital Humanities, should share their data –no matter how small– through large infrastructure initiatives like DARIAH and CLARIN in order to increase the textual coverage of linguistic resources.

Neutralising the Authorial Signal in Delta by Penalization: Stylometric Clustering of Genre in Spanish Novels

Summary

We propose a way to work with the stylometric distance measure Delta to analyse the subgenre of texts written by different authors. For that, we neutralize the author signal by penalizing the texts from the same writer, allowing the texts to have their shortest distances to other authors' works. We test this method with several subcorpora of Spanish prose and a corpus of French theatre.

Stylometry and Delta beyond Authorship

Since John Burrows proposed it in 2002, Delta has been one of the most used and researched methods in stylometry and authorship attribution. Burrows explained it as "expression of difference, pure difference" (2002: 269) and is based on basic statistical concepts like most frequent words, z-scores and the Manhattan distance between each pair of texts. Burrows closes his paper with an unanswered question about why Delta works so well.

Other researchers such as Hoover (2004b: 454), Argamon (2008), Plasek (2014) or Evert et al (2015: 79) have confirmed that we are still far from being able to answer this question. This lack of understanding has not stopped the stylometric community of trying to improve Delta (Hoover 2004a; Argamon 2008; Eder 2013). Smith and Aldridge (2011) have proposed Cosine Delta which gives the best results in different languages (Jannidis et al. 2015).

Since Delta is sensitive to aspects or *signals* like genre or period (Burrows 2002), the corpora for authorship attribution tend to be homogenous in those aspects. Research has been conducted to try to separate signals (Schöch 2013 and 2014) or selecting the words that contribute to them using Recursive Feature Elimination (Büttner and Proisl 2016). Jannidis and Lauer (2014) and Hoover (2014) show how Delta can be used to distinguish genre and periods within the works of a single author. Other researchers have used other methods such as classification (Hettinger et al., 2016; Underwood 2014) or logistic regression (Jockers 2013; Riddell and Schöch 2014) to similar ends.

Neutralizing Author Signal in Delta

Our proposal is to neutralize the author signal directly on the Delta matrix. We use a testing corpus of texts from three Spanish authors and three subgenres. Detailed information about the corpora, files, parameters and scripts is in our GitHub repository. We applied Cosine Delta (5000 MFW) with Stylo (Eder, Rybicki and Kestemont 2016) and visualized the resulting distance matrix with Python:

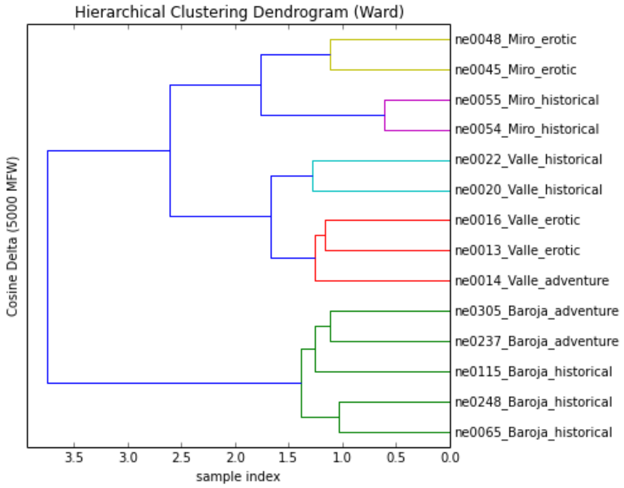

Figure 1: Dendrogram from Cosine Delta

As expected, the texts are clustered by author, with subclusters of subgenres. The underlying Delta Matrix contains distances between all texts:

Figure 2: Cosine Delta Matrix

We see a tendency of lower Delta values for documents of the same author (below 1.0) in comparison to documents of different authors (above 1.0). But what about the closest texts written by a different author? For the historical novel in column E, they are in the rows 14 and 15 and are historical novels, as well. This pattern is found for the majority of the texts. How could we cluster the texts preferring the closest text from other authors? And if we are able to neutralize the author signal, will we see noise or subgenre clusters?

Our proposal is to penalize the distances between the texts of the same author (cf. Lu and Leen 2007 for penalization in image clustering), making them closer to the average distance of texts of different authors, then cluster the neutralized distance matrix and measure the cluster homogeneity by author and subgenre.

We define the set of all documents by an author *a* as A_a, the collection containing all documents by all authors as *C* and total number of documents in the collection is defined as *c*:

$$A_a := \{d_1, \cdots, d_{m_a}\}$$

$$C = \{A_1, \cdots, A_n\}$$

$$c := |\bigcup C|$$

Note that each document is in exactly one author-document set A_i.

First, we calculate the average distance of texts of all pairwise different authors (in fig. 2, all the distances in black). We call this value the **mean of different authors or *M(C)*** and for this collection its value is 1.16.

$$M(C) := \frac{\sum\limits_{\substack{A_a, A_b \in C, a \neq b \\ d_i \in A_a, d_j \in A_b}} \Delta(d_i, d_j)}{\sum\limits_{A} |A| \cdot (c - |A|)}$$

Second, we calculate the **mean of the texts of each author a *M(A_a)*** (in fig. 2, the distances in grey).

$$M(A_a) := \frac{\sum\limits_{\substack{d_i, d_j \in A_a \\ i \neq j}} \Delta(d_i, d_j)}{|A_a| \cdot |A_a - 1|}$$

For each author, we subtract his/her mean value from the mean of different authors *M(C)* - *M(A_a)* resulting in the **difference of the author**. This value represents how far the texts of a specific author are to the mean of different authors:

author	mean	difference
Miro	0.607	0.552
Baroja	0.669	0.490
Valle	0.752	0.407

Figure 3: Means and differences of author

Third, we add the difference of the author *M(C)* - *M(A_a)* to the Delta values of text of the same author. This gives a Neutralized Delta-function as follows:

$$\forall d_i \in A_a, d_j \in A_b$$

$$\tilde{\Delta}(d_i, d_j) := \begin{cases} \Delta(d_i, d_j) & \text{for } a \neq b \\ \Delta(d_i, d_j) + (M(C) - M(A_a)) & \text{for } a = b \end{cases}$$

This converts the table from Figure 1 into a Neutralized Delta matrix:

Figure 4: Author-Neutralized Delta matrix

The values in grey are now in general above 1.0: the texts of the same author have been separated, showing relations between texts independently of authorship. Now the adventure and historical novels of Baroja in columns C and D have their closest text in works of different authors but belonging to the same subgenre.

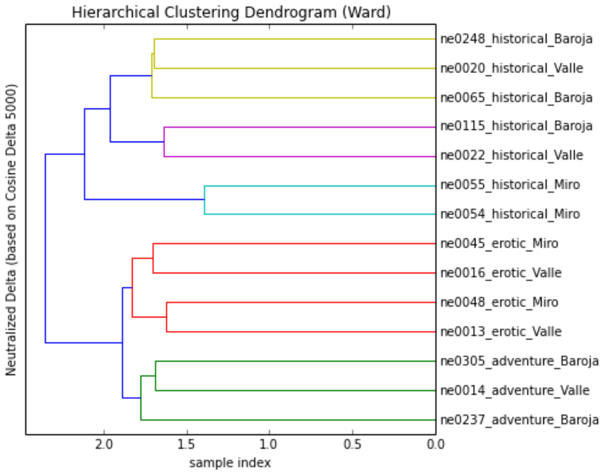

Fig. 5: Author-neutralized Delta dendrogram

In comparison with Figure 1, this dendrogram allows us to see new text relations beyond authorship but within subgenre, showing clusters with different authors but the same subgenre: for example, the cluster of historical novels by Baroja and Valle or the two very close subclusters of erotic novels by Miró and Valle.

Tests and Evaluation

For the evaluation, the homogeneity of the clusters (Rosenberg and Hirschberg, 2007) was measured. This measure yields values between 0 and 1. As ground truth, the metadata about author and subgenre have been used. The results for the dummy corpus:

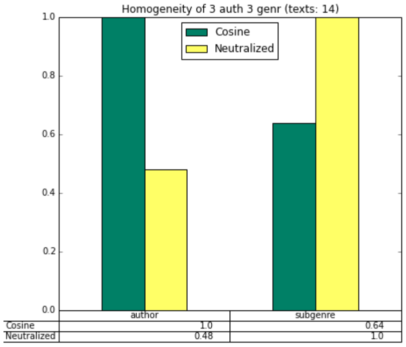

Figure 6: Homogeneity of Cosine and Neutralized Delta for author and subgenre

The homogeneity of the clusters of Cosine Delta (see fig. 1) are perfect for authors and much lower for subgenre, because the author clusters contain subgenre subclusters. The homogeneity of the clusters of Neutralized Delta (see fig. 5) is lower for authorship (as expected), but not for subgenre. In this case the neutralization of the author signal only deteriorates the homogeneity for authorship but improves the homogeneity for subgenre.

We have analysed different subgenres present in the whole corpus for test the method. We created subcorpora of historical, bildungsroman, erotic and adventure novels:

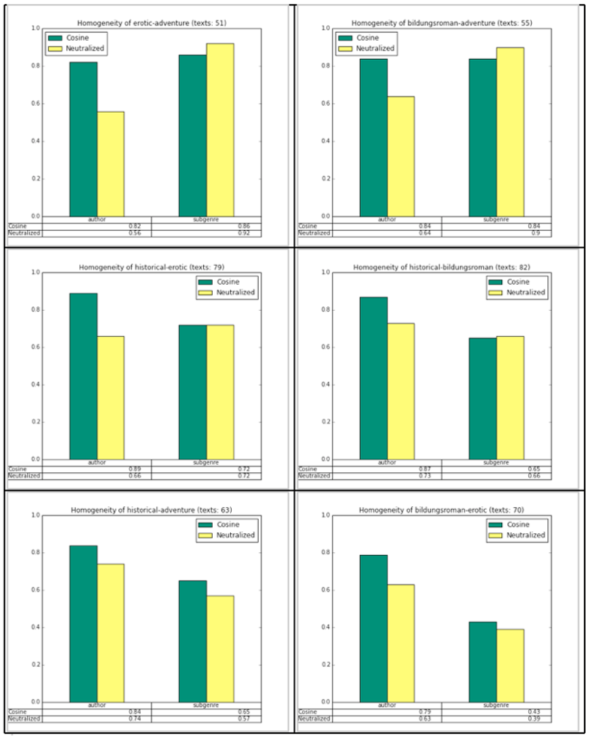

Figure 7: Homogeneities for Spanish prose subcorpora

As expected, the neutralization consistently deteriorates the homogeneity for author (between -0.26 and -0.1) while the homogeneity for subgenre is not deteriorated (between -0.08 and 0.06). The homogeneity for subgenre of adventure compared to erotic and bildungsroman get the best results (over 0.9) and they even improved on results with Cosine. Adventure novels are also best recognized in classification tasks (Hettinger et al. 2016). Subgenres which are very difficult to differentiate like historical and adventure (Pedraza Jiménez and Rodríguez Cáceres 1983: 672 and 1987: 459) get one of the worst results.

The results are similar when testing other corpora, such as a corpus of French drama (Schöch et al. 2015) and a corpus of Spanish American novels:

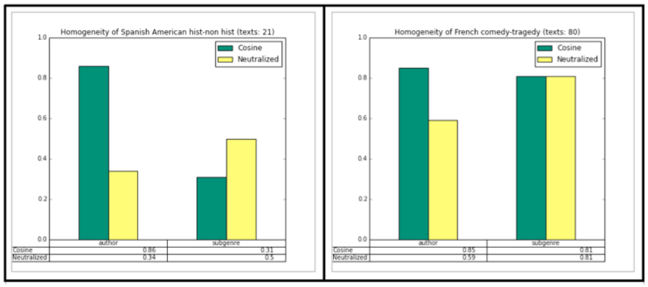

Figure 8: Homogeneity values for French drama and Spanish American novels

Conclusion and future work

Our main goal was to present a method to neutralize the Delta distances of the same author using the difference between the mean of the author and the mean of different authors. Tested on eight subcorpora, this procedure, as we expected, deteriorates the homogeneity of authorship clusters but maintains the subgenre homogeneity, improving it for some cases. That discovers relations between texts (see fig. 5) that were hidden by authorship. This procedure brings a new way of working with Delta beyond authorship attribution.

Both Cosine and Neutralized Delta show very different results for the comparison of different subgenres, something which points to the different internal structure of the subgenres. The comparison of very different subgenres (like adventure against erotic or bildungsroman) gets higher subgenre cluster homogeneity. Neutralized Delta could be used for comparing different corpora of specific subgenres and test the significance of the results to better characterize these subgenres. In an ideal scenario, we would like to test on a perfect balanced corpus where a set of authors are represented in all subgenres of the same period.

For future work, we will analyse how different parameters like versions of Delta or number of MFW affect the results. We also plan to transfer the approach to an earlier step in the Delta procedure and penalize the word z-score vectors.

We look forward to the feedback of the international DH community about this new use of the very effective “expression of difference, pure difference” which is Delta.

Acknowledgements

To avoid confusion regarding intellectual property, we would like to make it clear that the main idea and implementation are the work of the first author. Other authors have brought important remarks, feedback, some of the corpora and have helped with the redaction and the formalisations.

Introduction

The digital humanities (DH) are perhaps unique amongst humanities endeavours. They force us to confront the conceptual and ethical implications that attend the union of the humanities with engineering and organizational thinking. They demand attention to tools, methods, ethics, and pedagogy, but also organizational bureaucracy, human resource management, economics, and systems maintenance. Rather than merely prompting a bland mechanization of the humanities, as critics suggest, this offers a fascinating epistemological challenge. It challenges us to rethink how human meaning and knowledge are constructed, and how they will be remade as the twenty-first century progresses. This requires a step-change in our epistemic, ethical, and collective assumptions as much as our methods.

These issues are distilled in laboratory settings. Sociologist of science Karin Knorr-Cetina (1999) notes that labs function as blended communities, uniting researchers with technicians and administrators. Access to equipment, chemicals, data, and funding, impact the production of knowledge as much as pure research questions. Issues of finance and organizational power compete with creativity and the need for diversity. Scientists have been gaining insight into this since the nineteenth century, fostering traditions (and injustices) that are well understood . (Adas, 1999). Digital humanities labs challenge us to create parallel traditions, appropriate to the humanities and GLAM communities. King's Digital Lab, launched in November 2016, embraces this challenge, positioning itself as an experiment in infrastructural as well as conceptual terms.

Postphenomenological perspectives current in the philosophy of technology and Science and Technology Studies (STS) help explain our approach. Writers like Donald Ihde (2009b) and Peter Kroes (Verbeek, 2010) embrace the entanglement of humans with technological tools, systems, and processes, and meditate on the material reality that informs our experience of the world. They reject the Heideggerean critique of technology, based on the modernist division of subject and object, in favour of acceptance that entanglement with culture, technology, and ideology is not only unavoidable but provides a window into the nature of human experience (Ihde 2009a). Rather than mechanizing the soul of the humanities, digital humanities laboratories force us to confront our entanglement with technology, along with its enabling infrastructures and ideologies.

King's Digital Lab

King's Digital Lab (KDL) builds on a 30-year legacy in digital humanities at King's College London. The lab represents one half of a new digital humanities model, in conjunction with the Department of Digital Humanities (DDH). KDL provides software development and infrastructure to departments in the faculties of Arts & Humanities and Social Science and Public Policy, focusing on software engineering and implementing the systems and processes needed to produce high quality digital scholarly outputs. The department focuses on delivering quality teaching to its postgraduate students and growing cohort of undergraduates, and producing research outputs in line with its status as an academic department. In combination KDL and DDH include close to 40 staff, host 160 projects, served 130 million webpage views in 2014, and teach over 200 students.

KDL's business, operational, and human resource plans define its research values alongside its business and technological model. It has been established with 12 permanent full-time staff: director; project manager; analysts, software engineer, developers, designers; and systems manager. Contract and temporary staff are used as infrequently as possible, ideally to offer student experience in a software development environment. The HR model is explicitly designed to foster sustainable #alt-ac Research Software Engineering (RSE) career paths. All KDL team members, permanent or contract, are encouraged to use 10% of their time on personal projects (either on their own or in collaboration with colleagues), leading to work with Raspberry PIs, virtual reality, and an interest in maker culture.

The KDL model is based on deeply felt humanistic values, but reflects a level of organization required to manage entanglement with technological systems. The lab manages over 90 projects, including up to 20 that are active in some form, and ~5 million digital objects. The team manage over

180 virtual machines, on an infrastructure that uses 400GB of RAM and 27TB of data. New infrastructure platforms are being trialed that include access to cloud and high performance computing options, in a nod towards a future working with big data, visualization, and simulation. The goal is to facilitate a transition from twentieth to twenty-first century modes of computationally intensive humanities and social science research, but to do so in consciously humanistic terms.

In a rejection of a simplistically 'mechanized' future, development tools are proactively managed and the lab has a 'design first' philosophy (Verbeek, 2006). This is partly a way to manage the considerable complexities that come with advanced DH research and the delivery and management of multiple projects, but it also recognizes that digital tools and methods are, at their best, beautiful. Aesthetic and quality values can extend from front-end design to technological platforms, code, tools, and methods. Data, similarly, can and should be beautiful, not only in adherence to appropriate technical standards but in its conformance to scholarly best practice and deep domain knowledge. Infrastructure and systems, likewise, are always compromised by their material design and ideology (Russell, 2014), but decisions to choose open source components and emphasize access and sustainability enhances control and agency (Friedman et al, 2015).

To reduce complexity and improve sustainability, the lab uses the Python programming language, and Django web framework in preference to other options. The full technology stack is consciously oriented towards open source components, and a balance between functionality and sustainability.

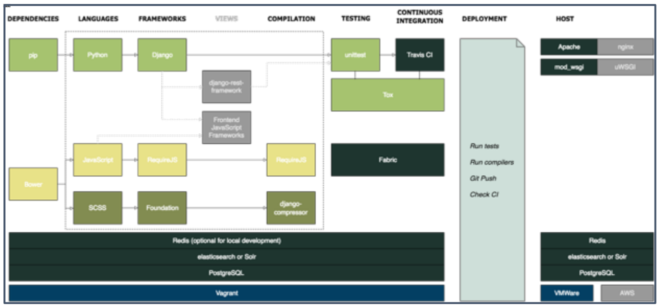

Figure 1

This level of organization helps us manage technology, but also promotes critical awareness: the current technological state of the lab is far from perfect, but it is under control and guided by known critical values. The concept of the 'laboratory' is important in this context. Rather than mechanization, it implies experimentation and risk, but also a certain intellectual seriousness. Scientists learned what a laboratory means to them over a century ago; the humanities and social sciences are only just starting to explore the implications. They are profound, not only in terms of the epistemological implications of putting tools between the researcher and the object of study (with inevitable technical constraints), but in terms of the ideological implications of using industry approaches to software development and financial management. Consciousness of this ensures the lab is sustainable, and can continue to support scholarship as well as the careers of our team members.

The technological inheritance of the lab is considerable. It includes over 90 live web-based projects, built using heterogeneous tools and programming languages by the (historic) Centre for Computing in the Humanities, (historic) Centre for eResearch in the Humanities, and the Department of Digital Humanities. Funding agencies paid for them to be built, but not to sustain them. Some Primary Investigators (PIs) have retired, or are no longer in contact with King's. Support for these projects is currently borne by the lab, generously supported by the Faculty of Arts & Humanities, but is being managed by an evolving archiving and sustainability plan that will assess each of the projects, determine their intellectual merit, and work with their owners to find the best way to maintain or archive them. The archiving and sustainability model used for this task will be published, as well as being included in the lab's Software Development Life-cycle (SDLC), to ensure sustainability will be considered on day one of every new project.

The organizational chart of King's Digital Lab is flat rather than hierarchical, reflecting an aspiration to be role-based and collaborative: a shared intellectual and scholarly space that exists to experiment with new approaches as well as deliver projects on time and budget. The scale is such that the lab design has needed to be out-sourced to multiple authors: director and project manager working with line management to define the business plan and financial model, analysts and developers developing the software life-cycle, UI developer leading the design vision, systems manager ensuring the infrastructure and networking model is appropriate. Together, it amounts to something complex and technologically dependent, but redeemed through a philosophy of shared ownership and conscious experimentation.

Networks of the Great Awakenings: Classification of Puritan Sermons by Word Usage Statistics

Michał Choinski
michalchoinski@gmail.com
Jagiellonian University, Poland

Jan Rybicki
jkrybicki@gmail.com
Jagiellonian University, Poland

Revivalism has always played a significant role in the social functioning of religion in the US. As argued by McClymond, "religious revivals are as American as baseball, blues music, and the stars and stripes" (2010, 306). This strong presence of revivalism in the American religious landscape translates into the considerable significance of revival preaching not only for the American pulpit practice, but also for American culture in general. One could argue that a certain continuity is discernible in the American revival tradition, and preachers of consecutive "Awakenings", starting with the Great Awakening, have utilized similar communicative strategies, analogous sets of cultural references, as well as persuasive ploys to forward the "New Birth" to their hearers and to spread the revival zeal. Billy Graham, the most celebrated televangelist of the 20th century, testified to the importance of this tradition when in 1949 in Los Angeles, during the "Canvas Cathedral" Crusade, he delivered to a contemporary audience the most notorious sermon of the Great Awakening (and, perhaps, of America's entire pulpit oratory), Jonathan Edwards's *Sinners in the Hands of an Angry God*. Graham was by no means a pioneer in this respect, as the 19th century American revivalists, like Charles Finney, eagerly fell back on the rhetorical heritage of the first Great Awakening sermons.

Crowds of thousands of people, the emotional reactions of the audiences which often bordered on mass hysteria, fervent theological debates and a surplus of publications played a significant role in the shaping of the early American ecclesiastical order. Similarly, the American rhetorical tradition was strongly informed by the revival developments in pulpit oratory, especially in the context of both the oratory of the American Revolution and the Civil War. New forms of preaching manifested the power of the spoken word, and propelled the dynamics of public debate in a period which was to prove vital for the development of American identity.

The study of American preaching tradition from the diachronic perspective seems particularly important. Different groups of preachers in consecutive Great Awakenings, (First 1735-1750, Second 1790-1840, Third 1850-1900, Fourth 1960-1980) appropriated the rhetorical models employed by the previous generations and built upon their output.

However, because of the sheer size of the available corpus, the comparative study of the preachers of all Great Awakening has been so far impossible. Stylometry based on word usage makes it possible to highlight the connections between particular groups of preachers, as well as to demonstrate the evolution of the American revival preaching tradition; and to confront these findings with the existing attempts at classification/chronology (Stout 1986).

In our study, 42 collections of sermons by individual preachers (one text file per preacher) have been collected, digitized and modernized to avoid an excessive chronological bias due to spelling differences; of course, purely linguistic bias could not be entirely eliminated. Of these, 13 are traditionally classified as First Awakening; 9 as Second; 19 as Third; the most traditionally controversial group, Fourth, is represented by Billy Graham alone.

Classification was made by comparing distances, or differences, between most-frequent-word frequencies of the texts using Burrows's Delta procedure (2002); the distance measure applied was "Cosine Delta" as proposed by Jannidis et al. (2015), implemented in the *stylo* package (Eder et al. 2015, 2016) for R (). The word frequencies were submitted to a consensus procedure of cluster analysis at word frequency vectors of 100 to 2000 most frequent words, and these results then served to produce network diagrams in *Gephi* (Bastian et al. 2009) using the gravitational Force Atlas 2 algorithm (Jacomy et al. 2014). This produces a network or a "map" of data points for the individual preachers' sermons; the closer and the thicker the links between them, the more similar they are.

Figure 1 presents such a network graph for the 42 preachers. The color coding follows the traditional division into four "Awakenings" (from First, green, through Second, yellow, Third, red, and Fourth, purple). A very strong evolutionary pattern emerges; apart from minor imperfections, the network shows a clear evolution from the earliest preachers to the most modern one, Graham. At the same time, the grouping of the data points suggest that a different classification might also exist in the dataset. This is why another algorithm available in *Gephi*, "Modularity," was used to discover these "communities," or groups (Blondel et al. 2008).

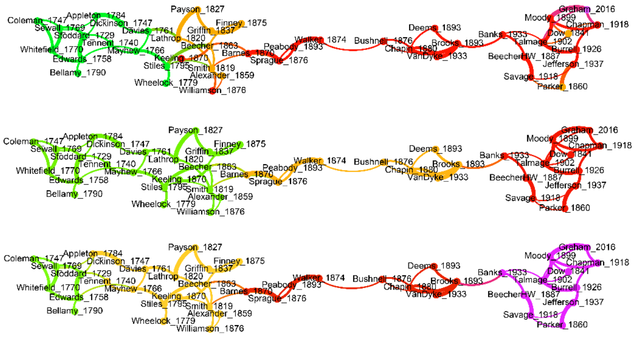

Figure 1. The four Great Awakenings in traditional classification (top); divided by modularity into 3 (center) and 4 (bottom) groups.

This produces two alternatives to the traditional division of the Revivalist movements(s). In the first of these (center), what is usually referred to as the First and the Second Great Awakening would be merged into a single group, while the traditional Third Awakening splits into early and late phases; the latter of which now also included the single representative of the Fourth. Perhaps more interestingly, computer-generated four Awakening communities (bottom) suggest a First only limited to some of Edwards's contemporaries, a Second that extends a little more than traditionally into the past, and again a limited early Third with an expanded Fourth.

This is of course not to say that the above results invalidate the traditional, or historical, division of American revivalist writing. But the stylistic (or, at least, stylometric) divisions are no less valid. Most-frequent-word usage is a significant element of distant reading; and such a distant reading of the Revivalism opens new avenues for close reading of the American homiletic tradition.

Remembrance of Contemporary Events: On Setting Up The Sunflower Movement Archive

Tyng-Ruey Chuang
trc@iis.sinica.edu.tw
Academia Sinica, Taiwan

Abstract

In the late evening of March 18, 2014, students and activists stormed into and occupied the main chamber of Taiwan's Legislature. The event set off the Sunflower Movement, signifying a turning point in Taiwan's history. Researchers at Academia Sinica arranged to acquire all the supporting artifacts and documentary materials in the chamber before the protest came to a peaceful end. In this paper, we discuss the issues in archiving and making available to the public a large collection of artifacts created by thousands of participants in a contemporary event. We demonstrate systems designed to encourage people to identify items of their own in the archive. We show how an accessible catalog to the archive can help people tell their stories hence collectively may strengthen the public's recollections about the movement.

Background

In the late evening of March 18, 2014, a small group of students and young activists stormed into the main chamber of the Taiwan's Legislature in protest of the hastily reviewed and pending signature of the Cross-Strait Service Trade Agreement (CSSTA) with China (Figure 1). The occupation of the Legislature would take several weeks and grow into an island-wide movement with strong popular support. In its aftermath it would amend the course of Taiwan politics, as well as its relation to China. It was a major contemporary event in Taiwan, and continues to influence the political landscape and societal reflection in the country. The occupation of the Legislature was streamed live, and when people vacated the chamber they left behind a massive amount of supporting artifacts and documentary materials. What would one do with these artifacts and materials, presumably soon to be abandoned, vanished and forgot? What could an archivist — or anyone who ever was involved in the movement — do in preparing for the future generations to remember the present events?

A few historians in Academia Sinica, Taiwan, seized this opportunity and reached a general agreement with the occupants to systematically collect what was in the Legislature main chamber before they would prepare to end the protest. Afterward Academia Sinica suddenly got hold of a large collection of artifacts created by thousands of participants in a contemporary event. In this paper we discuss a few issues involved in digitizing and archiving artifacts from contemporary events of this nature. We outline our approach to addressing them, and we present the current status of this archive. The archive is called the 318 Civil Movement Archive at Academia Sinica. More background information about it can be found at the archive website [About]. As the movement started on March 18, 2014, has since better known as the Sunflower (Student) Movement [W-en] [W-zh-tw], in this paper the term Sunflower Movement Archive and the term 318 Civil Movement Archive will be used interchangeably to refer to the archive initiated at Academia Sinica. Often we simply call it the Archive.

Principle

To strive for general access to the Sunflower Movement Archive probably was our topmost principle when we were starting to digitize the artifacts. This principle, however, shall be applied to a conflicting context of requirements and constraints. On the one hand, making the archive publicly accessible — on the Web of course — keeps Academia Sinica accountable to the activists (and to the public as well) about what it is doing. Academia Sinica will keep its promise in preserving all the artifacts it has acquired, and the proof is in the form of a Web catalog of all the digitized artifacts. On the other hand, as the artifacts are made by individuals, and some are of a personal nature (encouraging notes to the activists, for example), the individuals' personal privacy, publicity rights, as well as copyrights can be vulnerable when digital copies of the artifacts are made available for all to exam and use.

Because of these considerations, only thumbnail images of the artifacts are made available on the Web for the Archive. The thumbnails are still useful for artifact identification (more about this later), but they are of no plausible other values. In addition, sensitive information inscribed in the artifacts, such as recognizable signatures and phone numbers, has to be pixelated to prevent misuse. No doubt there are boundary cases challenging our judgments. Often we will rather be safe than be sorry, hence will not release even thumbnail images at all for some artifacts. Still, how shall we deal with a banner with hundreds of signatures, sent in by overseas students to support the occupants? Scrubbing out all the signatures from the digital image of the banner will surly defeat the purpose of such an expression of solidarity. We make it a general rule that if it is a form of public communication, it shall be made public, even if there are personal information (names, signatures, affiliations, etc.) on the artifact.

If what are made available are just thumbnail images and artifact metadata, a Web archive will not be too interesting. As participation to the movement is both personal and collective, we hope people will use the online archive to identify artifacts of their own (creation), and to make available high-resolution images of their artifacts to the public for general reuse. That is, we want the Web archive to be a conduit to help transit a collection of orphaned works into a domain of collective remembrance. A feature is built into the online catalog to allow registered users to identify artifacts of their own. Once identified, the user can choose to release the high-resolution image of the artifact to the public under one of the six Creative Commons Licenses, or more openly to elevate it to the public domain by using the CC0 Public Domain Dedication. Of course the claimant can choose to declare to reserve his/her copyright to the work. In this case, the high-resolution image will not be made public. To facilitate better search into the Archive, each item in the collection is annotated with rich metadata, including a transcription of the text appearing on the artifact (the words in a note, for example). People have used this feature to find and release artifacts of their making in spite of (or because of) the artifacts have been archived (and put online) for this historical event.

At the same time when the physical artifacts were being digitized, we also began to collect "born digital" documentary media such as photo images and audiovisual recordings. At the time of the Sunflower Movement, these media were widely dispersed on media sites (e.g. YouTube), social networks (e.g. Facebook), or Web storage services (e.g. Dropbox). After the event, these media may be removed for various reasons, buried in new materials, or hard to find. Many service providers where these media are hosted often scale down the uploaded originals into low-resolution media, transform them into less desirable formats, and/or strip out all the metadata embedded in the original media (e.g. EXIF data in photos). These tainted media are not for archival purposes. We chased down some of the most well-known citizen media activists who were broadcasting and reporting the events. We acquired batches of original files from them. By going after the original producers, we also get to keep better records of the provenance of the digital media in the collection. Many providers chose to donate the entire collections on their hard drives to the Archive, by using the CC0 Public Domain Dedication.

Use and Identification

We feel it necessary to have a Terms of Use (ToU) for the publicly accessible catalog to the Archive [ToU]. By this, we will be able to communicate clearly to the public the purposes of the Archive, as well as various conditions and considerations in using the catalog. As the catalog is free and open to all, even without registration, to search and browse the Archive, we do not want the ToU to sound discouraging. Still, the catalog is the outcome of a provisional project at a research institution. We cannot really warrant the continuity and accuracy of the catalog and its associated services (in particular when funding was very uncertain in the beginning). Nor should we be held liable for people's use of these services. The ToU keeps users aware, and requests their understanding, of the right of publicity, the right to privacy, and other rights of the individuals whose artifacts are collected — or whose appearances are recorded — in the Archive. We also worry about the Archive being used by the authority as a source of evidences to pursue legal cases. Therefore, specifically in the ToU, we ask all users "not to cause civil or criminal disputes," and "not to commit harassment, threat or other misconducts on any individual."

We now demonstrate how anyone can use the Archive. Let us use as an example the hand-written note shown in Figure 2. This item is a small post-it note written by a student from the Chinese University of Hong Kong [10531]. It is part of a large panel sent in by the students from Hong Kong to support the students occupying the Legislature [12958]. The panel is shown in Figure 3, with all the notes attached to it, as it is in the catalog. Each note attached to the panel has been individually digitized and cataloged; the note in Figure 2 is but one of them on the panel. Figure 4 is a photo of the panel hanging on the wall of the main chamber of Legislature during the occupation. As the hand writing in the note has been transcribed into text and becomes part of the item's metadata, one can search for it in the catalog using a few key phrases. In the note, the student says s/he is from the Department of Social Work (社工系). Using this three-character Chinese phrase, we search and indeed find this item in the catalog, as shown in Figure 5.

Would anyone actually use the catalog to search and identify his or her own artifacts? We asked this question ourselves when deciding to add functionality to the catalog to allow registered users to identify, online, artifacts of their own. We were not sure. But once the functionality is there, and after some publicity about our work on the Archive, some people do start to identify their works and mail us their Copyright Declaration and Release forms [Id]. Figure 6 shows a work of art [18247]. It was identified by its creator using the catalog to the Archive. After the identification, he also releases the art work under a CC BY-NC-SA 3.0 TW license. By identifying it, the work can now be attributed to his name (佐瑪, Zuoma). By releasing his works under a Creative Commons license, he allows us to make available high-resolution images of his works for people to download. Figure 7A shows the template of the Copyright Declaration and Release form. A customized form will be generated automatically once an artifact has been identified by its maker. The PDF form will have included all the necessary information (about both the identifier and the identified item). It need only to be printed out, signed, and mailed in — no stamp required (Figure 7B) — by the identifier to Academia Sinica.

Who is Zuoma, the maker of the art work [18247], and what does he look like? People may ask. We shall know as we happen to meet him in person! In Figure 8, he is holding his own work, now a part of the collection of the National Museum of Taiwan History (NMTH). Since November 2016, all physical artifacts in the Archive had been transferred to the museum by a mutual agreement between Academia Sinica and the NMTH. The photo was taken at a press event on 2016-11-14 at the NMTH, where a one-day conference was held on topics of preserving and archiving artifacts from contemporary events. By building information systems encouraging people to reconnect with artifacts that had been forced to be left behind, we aim to help resurrect and disseminate people's stories of the movement. In this particular case, we did get to learn why and how Zuoma made this and other art works in the Sunflower Movement.

Current Status

The catalog of the Archive has been online since March 2015, roughly one year after the events setting off the Sunflower Movement. So far we have not received any complaint about putting the catalog online. For long-term preservation, Academia Sinica has made arrangement with the National Museum of Taiwan History (NMTH) to transfer the Archive to the Museum. The information systems managing the entire collection of digital media, including high-resolution images of all the artifacts, are developed and released as open source software packages. As such, Academia Sinica and the NMTH can both host the digital archive on the Web. Currently the digital archive is still hosted at Academia Sinica even though all the artifacts had been transferred. The museum by itself has been collecting artifacts from various contemporary events for many years, including those from the Sunflower Movement. What Academia Sinica had collected were from the main chamber of the Legislature. The NMTH collects many more from other sources. There is a tentative plan between Academia Sinica and the NMTH to mutually enrich their digital collections on the Sunflower Movement.

An online recollection of the 318 Civil Movement, drawing from a group of individuals loosely connected to the people working on the Archive, was announced and made public on March 18, 2015, the first anniversary of the events. The recollection is a website expressed as a map of Taiwan covered with images and narratives; these are individual stories told with supporting materials drawn from the Archive or from other sources [Expo]. We imagine any person, any group of individuals, can use this catalog to the Sunflower Movement Archive to tell their stories. Each item in the catalog has a permanent link; anyone can use the links to weave stories about the various events in the movement.

Discussion

Remembrance of contemporary events can be both personal and collective. When artifacts are collected from contemporary events, individual and public access considerations constrained what shall and can be done with the artifacts. We hope we have maintained a balance in setting up the Sunflower Movement Archive. We hope our experience can draw some attention to, and incite more discussion about, the issues that are involved in building archives of contemporary events.

We would like to emphasize that the work on the Sunflower Movement Archive is but one among the many in the field of digital archiving and curation. We opt not to give an overview of the best practices, nor cite the many literature, in this brief paper as we fear we cannot do it properly with the current time and space constraints. A balanced and comprehensive survey of the field will be obligatory when an extended version of this paper is to be prepared. Nevertheless we note that our effort is most related to the many existing works in catching the ephemeral but personal (as compared to those in holding on to the permanent and institutional). We look forward to learning from and further extending the practices in post-disaster remembrance and diasporic recollection.

Acknowledgements

The work on the Sunflower Movement Archive has been funded by Academia Sinica and is a collaboration between the Institute of History and Philology and the Institute of Information Science. The author thank all the collaborators, especially Ming-Chong Hwang who initiated the collection of the artifacts and invited the author to join the project to archive them digitally. We thank Chi-Ling Lai, Shih-Ting Tang, and Chia-Hsun Wang for their enduring hard work on this project. Digital Memory Asia did all the digitization works. Word Gleaner Ltd. built all the information systems. Without their help, this project will not finish in time. We are very grateful to Shu-Jiun Chen for her advice on metadata, and to Shun-Ling Chen for her legal advice. We thank the Research Center for Information Technology Innovation, as well as the Office of Vice President Fan-sen Wang, Academia Sinica, for their support. Under a mutual agreement between Academia Sinica and the National Museum of Taiwan History, the entire collection of the Archive had been transferred to the Museum. We thank the Museum for giving the collection a most proper home.

Tempi Verbali e Strutture Narrative: l'Analisi Computazionale dei Morfemi Temporali nei Testi Narrativi Italiani tra Realismo e Modernismo

Fabio Ciotti
fabio.ciotti@uniroma2.it
Università di Roma Tor Vergata, Rome

Il problema: la transizione al modernismo nella letteratura Italiana

La transizione dal Realismo al Modernismo, che caratterizzò tutte le grandi letteratura nazionali occidentali nei decenni a cavallo tra l'800 e il 900, è uno dei periodi storico letterari che più hanno attirato l'attenzione della storiografia e della critica letteraria. Si tratta di un fenomeno di portata globale nelle culture occidentali che ha tuttavia avuto specificità stilistiche, scansioni temporali, espressioni di poetica e di produzione testuale diverse in ciascuna tradizione nazionale.

Nella storiografia letteraria italiana la categoria del "Modernismo" ha avuto una fortuna assai scarsa e solo nell'ultimo ventennio essa è entrata nel dibattito teorico, soprattutto per iniziativa di studiosi con prevalente orientamento comparatista (Luperini, 2014; Somigli e Moroni, 2004; Pellini 2004; Guglielmi, 2001). Per lungo tempo infatti si sono preferite nozioni storico letterario come quella di Decadentismo, soprattutto sulla scorta dell'influente lavoro di Salinari (Salinari, 1960) – e in generale di tutta la critica di impianto marxista storicista – secondo cui nel corso dell'ultimo decennio dell'Ottocento comincia a profilarsi, negli ambienti intellettuali italiani, quella "coscienza della crisi", che caratterizzerà la civiltà europea a cavallo tra i due secoli. Una crisi epocale dell'universo ideologico, culturale ed epistemico che aveva dominato nella seconda metà del secolo precedente, e che aveva dato vita alla stagione del Realismo sul piano letterario e del Positivismo su quello filosofico.

Questa periodizzazione e categorizzazione ha ovviamente determinato per lungo tempo notevoli difficoltà nel collocare le opere degli autori principali della letteratura italiana tra i due secoli: *in primis* Pirandello e Svevo, ma anche Tozzi e, in parte almeno, D'Annunzio (Castellana, 2010). Ma l'impianto analitico storicista alla base di tale inquadramento storiografico, concentrato sulla analisi delle poetiche e dei fattori socioculturali e strutturali di contesto della produzione letteraria, ha avuto anche una ulteriore conseguenza: fatta eccezione per alcuni grandi protagonisti, le cui opere sono state analizzate con grande attenzione, di rado si è cercato di verificare quali fossero i tratti testuali della produzione letteraria che permettessero di giustificare le proposte interpretative. La nostra ricerca si è posta dunque come obiettivo la ricerca di quei caratteri testuali intrinseci che fossero in grado di supportare o meno la tradizione interpretativa e storiografica.

Il paradigma metodologico: *distant reading* "critico"

Uno dei temi che hanno ravvivato il dibattito metodologico dell'ultimo decennio in ambito teorico e storico letterario è il paradigma del *distant reading* proposto da Franco Moretti (2013b). La proposta di Moretti, si noti, nella sua formulazione originale non voleva tanto promuovere l'uso di specifici metodi quantitativi computazionali nell'analisi dei testi (ciò che è poi divenuto preponderante nella "vulgata morettiana"), quanto piuttosto richiamare sulla necessità di affrontare una classe di problemi letterari che l'analisi tradizionale non riesce a descrivere correttamente.

Abbiamo più volte espresso le nostre riserve teoriche e metodologiche su alcuni aspetti e applicazioni di questo approccio, riconoscendone tuttavia la validità qualora esso sia applicato su domini e aspetti testuali di adeguato livello descrittivo (per intenderci, fenomeni che comportano l'analisi di corpora testuali vasti per individuare macro-fenomeni sincronici e diacronici), e la sua applicazione sia guidata da un adeguato inquadramento teorico e da specifiche ipotesi interpretative (Ciotti, 2014; 2016).

Crediamo che il problema che ci siamo posti e la sua dimensione cronotopica (la tradizione letteraria Italiana nel periodo che va dalla metà del 1800 al 1920) sia un candidato ottimale per una indagine basata sul *distant reading* e sui connessi metodi computazionali. Nel nostro studio abbiamo circoscritto il dominio dell'analisi alla produzione narrativa (sia nella forma romanzo sia nelle forme brevi) che, per vari rispetti, rappresenta in modo prioritario le problematiche individuate in apertura.

Per quanto riguarda l'inquadramento teorico, siamo convinti che un metodo di analisi computazionale riveste interesse in ambito critico letterario nella misura in cui fornisce dati osservativi che possano essere correlati a termini o nozioni teoriche adottate in una ipotesi interpretativa. Moretti nel suo lavoro più eminentemente metodologico, adotta la nozione di "operazionalizzazione" derivandola dalla epistemologia di P.W. Bridigman (Moretti, 2013a). Non concordiamo con il riduzionismo quantitativo presupposto nella accezione dell'operazionalismo di Moretti. Preferiamo concepire l'analisi computazionale non esclusivamente come un metodo quantitativo/numerico, ma come l'elaborazione di un modello formale funzionalmente isomorfo al dominio, cui si possono applicare processi computazionali. Da punto di vista critico si tratta di una versione computazionale della nozione di interpretazione critico/semiotica proposta da Umberto Eco (1990).

Il metodo: i tempi verbali nel testo e le tesi di Weinrich

Muovendo da queste considerazione metodologiche, il nostro lavoro ha richiesto in prima istanza l'individuazione del quadro teorico di riferimento. Da questo punto di vista ci è sembrato che lo studio del sistema dei tempi verbali secondo le indicazioni a suo tempo fornite da Harald Weinrich (1978) potesse fornire importanti indicazioni per l'analisi narratologica (Cazalé, 1989; Segre, 1985).

Per Weinrich i tempi verbali, nella loro dimensione testuale, non possono essere considerati esclusivamente dei veicoli lessicali atti ad esprimere il "passato", il "presente" e il "futuro" in quanto attributi del tempo reale. A tale visione "referenzialista" lo studioso tedesco oppone una teoria funzionalista dei tempi verbali, i quali, in quanto morfemi ostinati (presenti in gran copia, dunque, in ogni tipo di testo), fanno parte dei segni istruzionali a disposizione dell'emittente per orientare la ricezione del messaggio da lui emesso. I tempi verbali, dunque, appartengono alla classe dei *deittici*, poiché modellizzano la relazione tra il processo di comunicazione e il testo stesso: essi hanno la funzione di istituire e orientare il processo comunicativo, come istruzioni che il lettore deve seguire per recepire la catena sintagmatica correttamente (Weinrich, 1988).

Questo processo di mediazione avviene attraverso tre funzioni fondamentali che caratterizzano il sistema dei tempi verbali. Weinrich le individua in via empirica, basandosi su spogli e analisi di testi narrativi in lingue romanze, in tedesco e in inglese: opposizione tra tempi commentativi e tempi narrativi; divisione dei tempi tra funzione retrospettiva e funzione anticipativa; divisione dei tempi narrativi tra tempi del primo piano e tempi dello sfondo.

La distribuzione paradigmatica e sintagmatica dei tempi verbali nel testo, e le loro reciproche transizioni, dunque, costituiscono la manifestazione sul livello discorsivo del testo del rapporto comunicativo autore-mondo narrativo-lettore, e contribuiscono a manifestare alcuni importanti aspetti strutturali del testo narrativo:

1) rapporto tra autore/narratore e materia della narrazione (eventi e stati narrati);
2) realizzazione discorsiva dei rapporti tra intreccio e fabula;
3) articolazione sintagmatica delle sequenze narrative e descrittive.

Individuare come e in che misura questi aspetti del testo si articolino nel corpus sia a livello diacronico sia a livello sincronico ci permette di indagare il problema della transizione al modernismo nella letteratura italiana partendo da dati testuali, come ci eravamo prefissati.

Naturalmente la fenomenologia di questi elementi della semiotica narrativa non viene esaurita dalla distribuzione di tempi verbali, e a essa contribuiscono in misura notevole gli aspetti semantici della lingua. Si può dire che il sistema temporale dei verbi costituisce un quadro strutturale di fondo che consente al lettore di orientarsi nella ricezione del testo, uno schema rispetto al quale ogni autore costruisce le sue deviazioni idiolettali.

L'analisi

La configurazione quantitativa e sintagmatica dei tempi verbali nei testi è una proprietà testuale lineare che può essere soggetta a scrutinio computazionale con una relativa facilità - sebbene non siano pochi i problemi pratici da affrontare, soprattutto in ragione delle difficoltà che emergono nell'applicazione di sistemi di *part of speech tagging* al rilevamento dei morfemi temporali composti, e in generale a un linguaggio letterario che differisce notevolmente da quello dei *corpora* cui sono abitualmente applicati. Data la natura statistica dell'analisi tuttavia, una dose di errore statistico nel riconoscimento dei morfemi temporali è comunque accettabile.

Il corpus testuale di riferimento (composta da circa 400 testi unici) è stato estratto in gran parte dalla collezione del progetto Bibit. Alcune ulteriori edizioni digitali sono state estratte da *corpora* minori, tra cui le collezioni testuali prodotte dall'autore nel corso della sua pregressa attività didattica e di ricerca.

I risultati ottenuti finora sembrano indicare che esiste una mutazione nella configurazione dei morfemi temporali coincidente con la transizione di fase letteraria. Questa a sua volta è funzionale a una destrutturazione dell'impianto narrativo realista che avviene sia mediante una rimodulazione dei canoni tematici, sia mediante la trasformazione delle strutture formali e compositive dell'intreccio e del rapporto tra voce narrante/punto di vista e situazione narrativa. La transizione di paradigma culturale di fine secolo si riflette dunque all'interno dei sistemi modellizzanti secondari (Lotman, 1990), come quello letterario, nell'abbattimento dei confini tra i generi, nella commistione tra stili e registri espressivi e nella rifunzionalizzazione delle strutture narrative.

Une Preuve de concept pour la sémantisation et la visualisation orientée utilisateur de données archivistiques

Florence Clavaud
florence.clavaud@culture.gouv.fr
Archives Nationales, France

Emmanuel Château-Dutier
emmanuel.chateau.dutier@umontreal.ca
Université de Montréal, Canada

Notre présentation concerne un travail exploratoire aux objectifs qualitatifs, qui ambitionne de fournir des pistes de réflexion pour avancer vers la sémantisation des métadonnées des documents d'archives et la représentation à l'écran de ces données RDF, en vues multidimensionnelles, porteuses de sens et manipulables.

Trois organismes français (les Archives nationales de France, la Bibliothèque nationale de France, le Service interministériel des Archives de France) et un laboratoire de recherche canadien (le Département d'histoire de l'art et des études cinématographiques de l'Université de Montréal) se sont associés en 2015 pour réaliser une preuve de concept visant à démontrer qu'il est possible :

- de représenter en RDF, en veillant à la précision, à l'exactitude et à l'utilisabilité des triplets obtenus, des métadonnées archivistiques produites de différentes manières et selon diverses perspectives (celles d'institutions patrimoniales, celles d'un chercheur) ;
- d'enrichir les triplets obtenus en créant de nouveaux triplets, qu'il s'agisse de procéder à des alignements ou d'établir de nouvelles relations par inférence ;
- de produire une interface de recherche et d'exploration analytique et graphique qui soit dynamique, ergonomique et signifiante, sans sacrifier la granularité informationnelle ni la lisibilité.

Il s'agit donc de réaliser un démonstrateur, sous la forme d'une application web construite en utilisant des composants libres, dont les sources seront placées sous licence libre et déposées dans un entrepôt public.

Cette opération est relativement complexe. Il n'y a pas de réel précédent dans le domaine des archives. De plus, jusqu'à ce jour, il n'existait pas d'ontologie générique du domaine. Enfin, il n'existe pas a priori de librairie ou logiciel satisfaisant directement la totalité des besoins, en particulier pour ce qui concerne la visualisation des jeux de données.

Les bibliothèques, comme la Bibliothèque nationale de France (avec *data.bnf.fr),* et plusieurs musées, se sont lancés dans la conversion en RDF de leurs métadonnées et dans la réalisation d'interfaces de présentation de ces données, dès lors que des modèles conceptuels et ontologies appropriés ont été disponibles pour représenter leurs collections (CIDOC-CRM et FRBR). Par contre, si divers projets spécifiques ont déjà, soit produit des ontologies pour la description des archives et mis en œuvre ces ontologies (par exemple le projet LOCAH, dont les résultats sont consultables via *The Archives Hub Linked Data*), soit cherché à produire des représentations analytiques ou graphiques de ces descriptions, jusqu'ici ces réalisations n'avaient pas en même temps les ambitions de la généricité, de la complétude et d'une grande précision.

Il a fallu attendre fin 2016 pour la publication d'un modèle conceptuel global pour la description des archives (*Records In Contexts-Conceptual Model* ou RiC-CM) ; l'ontologie OWL correspondante, *Records In Contexts-Ontology* ou RiC-O), qui est l'ontologie de référence pour notre projet, sera publiée en 2017.

En outre, si la data visualisation est aujourd'hui devenue, en s'appuyant sur des technologies de plus en plus performantes, un important domaine d'action et d'innovation pour les humanités numériques, il est à notre connaissance encore très rare de trouver articulés la dimension temporelle, très forte en archivistique et en histoire, et une représentation précise, en graphe, d'objets historiques et des différents éléments de leur contexte, le tout étant susceptible de former un réseau très dense. Ainsi, les divers projets réalisés jusqu'ici présentent uniquement de façon relativement simple les agents et les documents (bibliothèque publique de la ville de New York), ou encore uniquement des réseaux d'agents (SNAC), ou encore des agents, leur histoire et leurs relations dans une perspective diachronique, mais pas les ressources documentaires liées (*Kindred Britain*).

Dans le cas de notre projet, nous avons commencé par choisir un périmètre pour les jeux de métadonnées source et préparer ces jeux de métadonnées, chaque partenaire travaillant de son côté, selon sa propre perspective, tout en respectant quelques règles élaborées en commun.

Les jeux de métadonnées sont composés de notices descriptives d'organismes et personnes physiques acteurs dans deux domaines fonctionnels de l'administration française (la gestion des monuments historiques et bâtiments civils des années 1795 à nos jours ; la gestion des bibliothèques publiques et de la lecture du 19e siècle à nos jours) et d'instruments de recherche archivistiques décrivant les ensembles documentaires produits par ces entités. Ils sont conformes aux standards archivistiques actuels que sont les normes ISAD(G) et ISAAR(CPF) et leurs transpositions techniques, la DTD EAD 2002 et le schéma XML/EAC-CPF. Nous avons choisi de procéder nous-mêmes à la sémantisation de ces jeux de métadonnées. Un vocabulaire des fonctions des entités encodé en SKOS/RDF, le seul à avoir été produit collectivement, s'ajoute à ce corpus.

Un cahier des charges a été élaboré, une consultation lancée et une société de services a été choisie fin octobre 2016 pour concevoir et réaliser le démonstrateur. Elle réalisera le travail selon une approche agile, en interaction forte avec l'équipe projet, qu'il s'agisse d'analyser l'ontologie et les triplets RDF fournis en entrée, de bâtir des scénarios de recherche, d'alignement, d'enrichissement ou de visualisation, ou de tester les versions successives du logiciel.

Comme le projet sera achevé fin octobre 2017, une version quasiment définitive du prototype devrait être disponible en août 2017. Un bilan critique, méthodologique et prospectif sera ensuite réalisé et publié par les entités impliquées. En avant-première, après une présentation rapide des objectifs, des enjeux et de l'historique du projet, nous nous attacherons à évoquer deux de ses aspects principaux :

- la mise en œuvre, pour la représentation en RDF des métadonnées archivistiques retenues, de l'ontologie RiC-O : présentation de l'ontologie et de ses principes de conception, discussion des choix d'adaptation qui ont été faits pour les besoins du projet, présentation des résultats obtenus, évaluation de ces résultats en ce qui concerne la granularité d'expression et les possibilités de raisonnement induites ;
- la conception de l'interface de recherche et de visualisation : présentation de la méthode suivie, des choix faits et des résultats obtenus, de leur intérêt et de leurs limites pour l'utilisateur final, que celui-ci soit un chercheur averti ou un amateur moins connaisseur des concepts archivistiques.

Introduction

The standard process for negotiating legal and quasi-legal texts over more than two hundred years has been a parliamentary one that (with variations) is still recognizable as the one described in Thomas Jefferson’s *Manual of Parliamentary Practice* (1801) (U.S. Government Publishing Office, 2016; May, 1844). Proposals are examined by a series of committees, amendments being proposed and voted on throughout this process. Since the late eighteenth-century, many of these negotiations of historical note have left records that record the proposals made and the outcome of decisions taken. Such records are difficult to read—especially when they concern any protracted or complicated process of negotiation, since it rapidly becomes impossible for a reader to keep track of the state of the documents under discussion. Fully comprehending the records if not read in chronological sequence is impossible.

Building on code written for collaborative document editing, we have built a sophisticated, web-accessible platform for the study of negotiated texts. We kept the underlying data-model as simple and generic as it could be while modelling the various procedures suggested by a range of Parliamentary Procedure handbooks. We considered the needs of several distinct classes of users — those doing the work of data-capture, those reviewing that work, those wishing to comment on the detail of the text, producing secondary materials for a variety of audiences, and those wishing to navigate through the material for a variety of purposes.

Initial application

One such process of negotiation was that which created the United States Constitution. The Records of the 1787 Convention, despite being imperfect and not (initially) intended for public release, in fact enable a detailed reconstruction of the work of the Constitutional Convention. These records have been available in various printed forms since 1819 when the official *Journal* was first printed; these printed records have been digitized as both images and transcribed text (Lilian Goldman Law Library, 2008; Silverbrook and Johnson, 2007; National Archives Catalog, 2016; Library of Congress, 2016). While indexing and searching increase the utility of both paper and digitized versions (by allowing readers to discover when particular topics were debated), neither format allows the reader to understand the full context of a particular debate. This is of no small importance, because opinions of participants in the negotiations about particular matters shifted as surrounding questions were answered one way or another.

Other digital projects

Whereas the *Comparative Constitutions Project* has pioneered the comparison and display of finished constitutional texts (Elkins and Ginsburg, 2005), and some other web projects have attempted to make the text of the United States constitution easier to navigate (Surden, 2015), our project focuses instead on the process of negotiation. Other projects have attempted to overcome the limitations of the Convention's records by giving users narrative outlines of the key events in a way that can guide their reading (Lloyd, 2016; Linder, 2016; EDSITEment, 2016). More generally, websites tracking the progress of Parliamentary debates have focused on **milestone** moments in the history of texts, rather than letting users track the detail of a document's evolution (Parliament, 2016; Tauberer, 2004).

Challenges

The records relating to formal negotiations are typically a set of minutes that record of proposals and the votes taken upon them. The principal aim of those recording the minutes is to facilitate the record-keeping process necessary during the work of committees, not to provide later readers with an easy way to reconstruct any particular moment. Each formal proposal to amend a document has at least two contexts that are relevant to readers — what does the document look like when the amendment is proposed? what does the document look like when the amendment is approved or rejected? Due to the nature of committee work, these contexts may differ significantly. Making sense of these records, therefore, poses a significant memory-burden on readers. Detailed and specific discussion of issues presented by these records is hampered by the need for authors to provide their own reconstruction of elements of this process, presented in a narrative form that is necessarily partial and can itself become difficult for readers to follow.

This problem might have been partially addressed using creative re-purposing of either version-control systems designed for computer-science applications (such as the tools *rcs* (GNU, 2013), *git* (Software Freedom Conservancy, 2016), or *mercurial* (Mercurial, 2016)) or else the creation of a layered XHTML document (The University of Virginia Press, 2009). However, we rejected these solutions as being either incapable of fully capturing the nature of the source material or else as likely to result in a fragile platform that would have been too much tied to the specific documents and unsuitable for more general applications. Since future work will compare different negotiations, a more generic platform that could work with a variety of sources with minimal new coding was required.

Our solution

Quill is a newly developed platform for the study and presentation of formal negotiations. It was developed initially with a view to presenting the records of the 1787 Federal Convention that created the Constitution of the United States, but was designed to be a generic platform applicable to a wide range of materials, including the creation of constitutions, treaties, and legislation. The model captures formal negotiations — that is those where there is a procedure of considering and deciding upon discrete suggestions for the wording of documents, and where minutes capturing these deliberations have been taken.

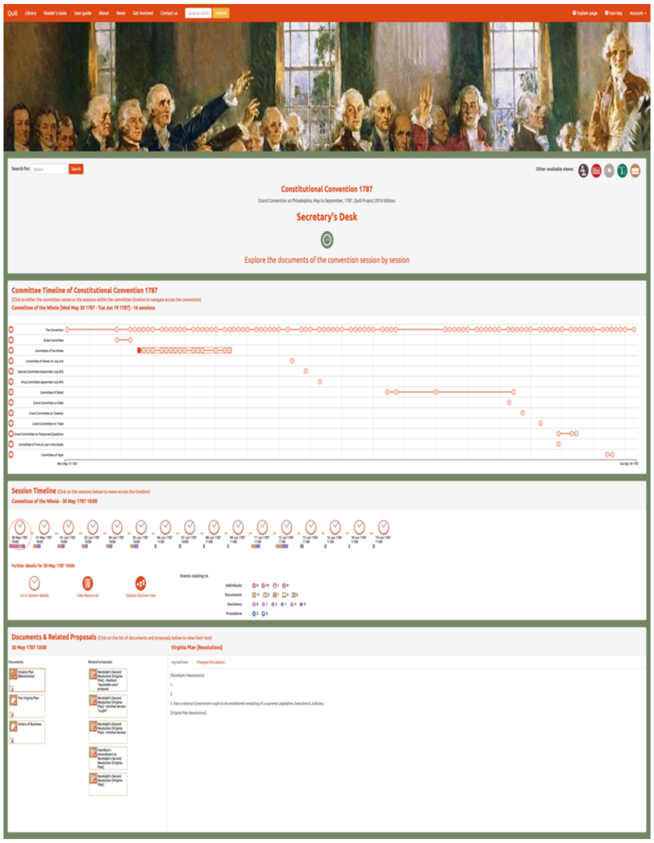
An innovation was to present not merely the reconstruction itself but to integrate a publishing platform that would allow authors to present their own commentary on the material in a way that would allow analysis to be presented alongside specific events within the timeline.

Links to relevant material held on other websites (for example, images of the original manuscripts) are similarly presented to users where relevant. In this way, the website integrates with existing materials, enhancing their value as well as its own and avoiding duplication of effort. We encourage such co-operation with other projects through machine-readable interfaces, a flexible permissions system and a system of **resource collections** that allow third-parties to manage links to their own assets and control how they appear within our platform.

For the 2016 release we relied on the 1911 edition of the Convention Records published by Farrand, even though we know these to be imperfect transcriptions of the surviving manuscripts. This choice allowed us to focus on the development of the software platform. The Quill Platform is capable of presenting different versions of the same event, and future work using the original manuscripts will refine our presentation of the records.

Supporting information–seeking and exploration

Negotiations of this type are extremely complex and assisting users to access the information they require is a challenge. In our public interfaces, we have guided users to access material in several ways. To acclimatize users to the idea of navigating the history of an evolving text, we present a *Secretary's Desk* view, which allows users to navigate the state of documents as they existed at the end of each committee session (see Figure 1).



Constitutional Convention 1787

Grand Convention at Philadelphia, May to September, 1787, Quill Project 2016 Edition.

Secretary's Desk

Committee of the Whole [Wed May 30 1787 - Tue Jun 19 1787] - 16 sessions

Session Timeline (Click on the sessions below to move across the timeline)

Committee of the Whole - 30 May 1787 10:00

Further details for 30 May 1787 10:00:

Documents & Related Proposals

Virginia Plan [Resolutions]

Figure 1: The Secretary's Desk for the Committee of the Whole on the 30 May 1787

This view hides much of the complexity of the negotiations, but allows new users to quickly grasp the concept of our reconstruction. We also present visualizations that allow users to explore the structure of negotiations through a variety of tree-diagrams (Herman, *et al.* 2000) (see Figure 2) and sunburst-style (Stasko, *et al.* 2000) visualizations.

The role of individuals and specific delegations, as well as voting patterns, are presented in separate visualizations. All of these views guide users who need more detail down to views that present the work of individual committee sessions moment by moment. Users looking for information on a specific topic are guided towards a search tool. In addition, users can also navigate the platform through a variety of resource and commentary collections, making it possible to provide users with a more guided experience.

Conclusions and future work

The process of negotiating the constitution was complicated (we have modelled close to 4,000 discrete events), and our presentation transcends the possibilities of narrative accounts while making access to and intelligibility of the extant sources much quicker and of greater utility for a broad range of users. The model system itself is content-agnostic and could be used to model a wide range of similar processes. Future work will continue to enhance the user experience both through refinement of the visualizations and user interface, and through the creation of guided views in to the material in collaboration with others, as well as expanding the range of material.

Wider public engagement and education is a key aim of this project. We are collaborating with non-profit organizations in the United States to develop guided views suitable for classroom use and integrated in to existing curriculum materials.

Getting at Metaphor

Katharine Coles
katharine.coles@utah.edu
University of Utah, United States of America

This paper will discuss how our newly prototyped POEMAGE visualization tool (see McCurdy et al, 2015), created to identify and visualize complex sonic relationships within individual poems, has provided poetry scholars with new ways to identify and conceptualize metaphor, which has previously been considered computationally intractable because of its semantic and syntactic complexities. It focuses not on the tool's technical details but on the ongoing re-theorization of poetry it has engendered,

Close readers are trained to connect every element in a poem to every other in an ambiguous, shifting complex of meaning, which the reader, bringing her own complexities to the process, activates. This poetic dynamic makes computational analysis and visualization of any aspect of poetry a challenge. The goal of our research team has been to take a single poetic element—sound—and treat it computationally and visually at a level of complexity that will make POEMAGE useful to poets and scholars performing sophisticated close readings of poetry, even as it makes poetry more accessible to students and casual readers. Though sound interacts with the other features operating within a poem, unlike most other features it can be looked at in its own terms and is subject to computer analysis through quantification.

As we began, poet Julie Gonnering Lein and I sought to preserve poetry's qualitative, aesthetic experience; computer scientists Miriah Meyer and Nina McCurdy sought to address open questions in their field. Both goals required moving beyond what the machine could already do. Off-the-shelf software can see exact rhyme quickly, as can a good reader—who will swiftly move on to look for sonic relationships that don't replicate themselves but enact disruptive changes that are hard to identify computationally. To capture the progression of sonic clusters as they repeat in different and evolving combinations not only within but across syllables presents a computational problem that required our technical team to develop RhymeDesign, which allows users to query a broad range of sonic patterns within a poem and to design custom templates to query patterns we haven't imagined. Built on top of RhymeDesign, the POEMAGE interface visualizes and allows users to explore interactions of the queried patterns.

In performing this work, we have looked for (and not yet found) computational breakthroughs that might bring metaphor within reach, a process that has required us to consider closely how metaphor works. The difficulty with metaphor inheres even in simple instances. Getting the machine to understand why "Hope is a bird" (or, more problematically, "'Hope' is the thing with feathers") is a metaphor but "Juliet is a Capulet" and "Karen is a Carpenter" may be either similar or different statements of fact is not straightforward.

Poets as different as Dickinson and Donne play complex metaphors out across entire poems in elaborate and shifting figural structures. To develop a tool that can reliably identify metaphoric relationships as POEMAGE identifies sonic relationships—in real time across the entire poetic field—would require the solution of multiple open problems in computer science.

However, recent readings of poems by Dickinson and others, undertaken using POEMAGE, suggest that it is possible to use the tool to access some metaphors not directly but indirectly, leveraging the fact that both rhyme and metaphor operate by substituting one word for another that is different-but-similar, and that inevitably sites of sonic difference-in-similarity point to semantic difference-in-similarity as well. In close reading, we have noted that places the machine marks as being sonically "interesting" are also sites of metaphorical action, and that this action often inheres in, rather than simply existing alongside, the sonic relationships being indicated by the tool. This inherence can emerge through various kinds of sonic relationships, including but not limited to homonyms like "knot" and "naught," which POEMAGE shows in Bradstreet's "Prologue," and eye-rhymes like "blood" and "mood," which it picks up across Pelizzon's "Blood Memory," about menstruation. In presenting these words as related, even conjoined, the machine opens a space for us to tease out figural connections between a loop in a rope and nothingness, or menstrual blood and emotional pain.

A more complex example of metaphor developing through sound occurs in Dickinson's #313:

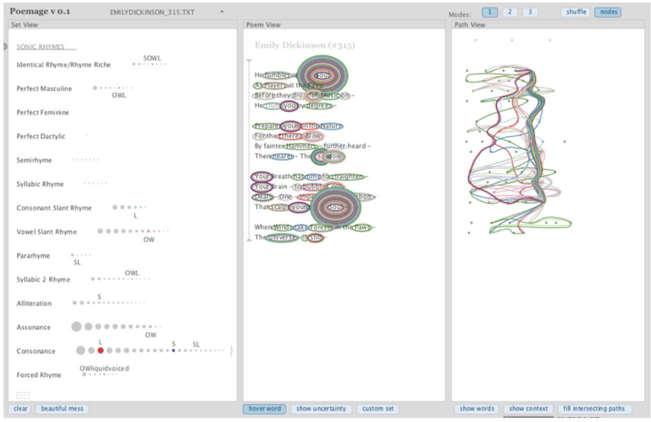

Figure 1: The user selects from the sonic rhymes available in the left-hand panel. The middle panel shows by color which words are implicated in a particular rhyme and which share phenomes. The right-hand panel shows how various rhymes flow through the poem.

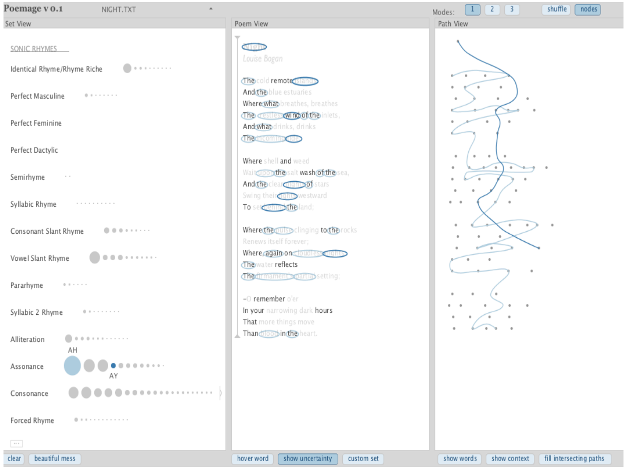
The visualization, which shows words that connect with "soul" through specific sonic relationships, makes clear at a glance that "soul" is sonically implicated with virtually every other word in the poem, though of course it is more strongly associated with some words than others. Its identification with "you" and "your" is notable, but I am more attentive to its strong links to "so" (a perfect rhyme and identical except for one dropped phoneme), "slow" (which deploys exactly the same three phonemes, with the second two reversed), and "still," which begins and ends with the same phoneme. Here, then, the "soul," identified with "you," is also sonically and so (because words mean) semantically identified with, in this order, intensity, slowness, and stillness. Beyond this, the tool invites an unlikely leap: the connection of "soul" with the poem's last word, "paws"—a big enough stretch that I am not sure I would make it without the tool's suggestion. This sonnet, which ends with what should be a rhymed couplet, teases by failing to do so. However, the tool's connection of "paws" with "slow" and, through "slow," to "soul" and finally "still," may suggest to the attentive reader an absent but implied homonym, "pause." Here, through an indirection of sound, the poem creates a semantic "rhyme" between "paws/pause" and "still."

Another case arises from our group's interest in uncertainty analysis, rooted in our understanding of ambiguity as a fundamental function of language, which led us to include in POEMAGE a "show uncertainty" button. Even beyond vagaries of accent, numerous words—*tear* comes to mind immediately—can be pronounced in more than one way, and mean differently depending on pronunciation. Every such word requires the machine to make a "guess"—a statistical prediction—about how the word is pronounced within the poem. The "show uncertainty" button allows the user to see words with alternate pronunciations as well as how the machine has chosen to pronounce them.

In "Night" by Louise Bogan, the tool mishears [short i] "wind" as [long i] "wind" (note that it rhymes with "tide":



Night
Louise Bogan

The cold remote islands
And the blue estuaries
Where what breathes, breathes
The restless wind of the inlets,
And what drinks, drinks
The incoming tide;

Where shell and weed
Wait upon the salt wash of the sea,
And the clear nights of stars
Swing their lights westward
To set behind the land;

Where the pulse clinging to the rocks
Renews itself forever;
Where, again on cloudless nights,
The water reflects
The firmament's partial setting;

–O remember o'er
In your narrowing dark hours
That more things move
Than blood in the heart.

Figure 2

Given its instructions, and the overwhelming probability that any one-syllable word comprising a beginning consonant and "ind" will have a long and not a short vowel, the computer had little choice but to make the "judgment" it did, even though the proficient *human* native speaker would not make this delightful mistake. In this "mishearing" of the poem, an inlet winding becomes "restless," and in this restlessness the central metaphor of the poem takes shape. Through such reading, we can see that tools designed to help forestall error in science may reveal disturbances that add to the richness of a poem by opening interpretive space and not only the possibility for but the actual presence of metaphor.

Of course, "getting at metaphor" in this oblique way, even if we give it a separate button in the tool, is not the same as creating a tool that will algorithmically identify and visualize metaphor through its syntactic or semantic construction. However, in some cases this method may still be useful, especially for users who believe, as we do, that the purpose of any visualization is not to replace human reading but to send us back to the poem. An unexpected by-product of our tool, it is already provoking rich readings, which show that shaping our queries about sound so that the machine can answer with metaphor helps us understand dynamics inherent to poetry, which invites readers to connect every feature to every other feature. Thus, POEMAGE furthers the larger goal of reliably identifying metaphor through computational methods. It also suggests ways forward in our overarching goal of identifying such complex features for visualisation in their own right.

These are just a few instances among many in which POEMAGE queries, by locating sonic difference in similarity, have identified places in poems that are not only sonically but metaphorically rich. Though we often believe the complexity of language may create an obstacle to the computational analysis of poetry, this argument represents a re-theorization of ways in which a tool originally meant to aid in one kind of analysis can give access to information and insight not originally predicted or even sought, not in spite of but because of poetry's linguistic complexity.

Tracing Swerves of Influence: text reuse and the reception of Lucretius in 18th-century England

Charles Cooney
chu.cooney@gmail.com
University of Chicago, United States of America

Clovis Gladstone
clovisgladstone@gmail.com
University of Chicago, United States of America

Over the past several years, as part of a Digging into Data Grant and in conjunction with Oxford University’s e-Research Centre, the ARTFL Project at the University of Chicago has been developing a large-scale online resource that allows scholars to examine text reuse in the 18th century. We used sequence alignment algorithms to compile a database of textual repetitions found in the Gale-Cengage *Eighteenth Century Collections Online* (ECCO) corpus, which contains the 200,000 works that represent most of the printed literary and scientific output in Britain from 1700 to 1799.

At Digital Humanities 2016 in Krakow, we presented the methodology and algorithms we used to identify these reuses and showed the early results of our work (Roe et al, 2016; for earlier discussions of this project, see Roe et al, 2015 and Abdul-Rahman et al, 2016). For the upcoming

Digital Humanities conference, our presentation will have two facets. First, we will outline the technical and editorial approaches we took when building the final version of the alignment database to maximize its usability and usefulness as a scholarly resource (See the *Common Place Cultures* project site, and its page on the University of Chicago domain). Secondly, we will discuss a use case of the database in which we examined reuses and citations of the first-century BC Roman poet, Lucretius, as a means to get a broad understanding of the 18th-century reception of the *De Rerum Natura*, the philosophical poem that proposes a materialist conception of the universe.

To construct the database, we used the PhiloLine (see Horton et al, 2010) sequence aligner to identify many millions of similar passages in the often low-quality OCR of the ECCO dataset. These passages range from a handful of words to large extracts of documents. We then used a similar passage matching algorithm to identify passages that were reused many times. The resulting database allows users to track specific passages, identify citations of specific texts in later texts, and find borrowed passages in later documents of an author's oeuvre.

As the creators and users of our navigational tool, we had to decide on the nature and scope of research the database should support and then strike balances between feasibility, usability, and performance. One of our earliest concerns was to allow users to get a fairly long view of textual reception/citation. To be able to identify the true source of any given reuse, we made the editorial decision to include texts that predated the 18th century. We therefore extended our alignment detection procedure to a variety of curated datasets such as the King James Bible, Classical Latin texts, and EEBO-TCP.

Our extended alignment experiment was extremely successful: we uncovered more than 40 million text reuses across our multiple datasets. At the same time, this success raised the problem of devising a way to explore result sets of a huge scale efficiently, leading us to focus on building a navigation tool that provides filtering and sorting control to users in a precise and intuitive way. We added various UI elements to guide users in their exploration: a list of the most commonly cited authors just a click away from the input box; a faceted browser to help users narrow down search results; and a timeline view of any given text reuse (see Appendix for screenshots) Combined together, these choices greatly enhance the capabilities of our web application, making it a tool that can very easily track intellectual influence from the classical Latin era to the late 18th century.

In the second part of our presentation we will discuss a use case of our database, examining citations of Lucretius's Latin text in 18th-century English texts. Our aim was to fill in gaps in current scholarship and discover the aftereffects of the resurgence in interest in Lucretius's work, the *De Rerum Natura* (*DRN*), at the middle of the 17th century in England (for example, Greenblatt (2011) gives only very cursory treatment to reception of Lucretius in the 18th century in *The Swerve*). During this so called "Epicurean revival," John Evelyn (1656) and Lucy Hutchinson (unpublished) were the first to translate, either in part or whole, the *DNR* into English. Walter Charlton published his *Physiologia Epicuro-Gassendo-Charltoniana, or, A fabrick of science natural, upon the hypothesis of atoms* in 1654. And though Thomas Hobbes never cites Lucretius directly in his *Leviathan* (1651), the Latin poet's ideas about the material nature of the universe are a distinct antecedent to Hobbes's mechanical philosophy.

Even around the time of the revival, the reception of the *DRN* was vexed. Lucretius's statements about the materiality and mortality of the soul, the role of chance in the universe, and the detachment of the gods were far too radical ever to gain wide acceptance in early modern England. In the backlash against Hobbesianism in the 1660s, Lucretius was a prime target for criticism. Cottegnies (2016) argues that the backlash against Hobbes's ideas in the 1660s also marks the end of the Epicurean moment. Theologians writing against Hobbes attacked Lucretius's atheistic materialism. And though Lucretius's stature as a poet continued to grow, praise for *DRN* was almost always tempered. His more extreme ideas were to be dismissed or ignored. In the notes to his translation of *DRN* in 1682, the first complete translation published in English, Thomas Creech argued against Lucretian and Epicurean attitudes toward the soul and divinity (Creech and Dryden, 1700; these citations refer to the text published using the PhiloLogic build of eebo). John Dryden, the preeminent arbiter of literary taste of his era, quoted Lucretius often in his plays and included translations of select passages in *Sylvae* (1685). In his preface to that collection, Dryden praised the directness of Lucretius's poetic expression, pointing out the "positive assertion of his Opinion" and his "Magisterial authority." But the subject of his poem is "naturally Crabbed" and the poet himself is "often in the wrong" (Dryden, 1685; text published online by Philologic).

Reuses and citations found in the Digging into Data database suggest that this basic framework for understanding Lucretius largely played out across the 18th century. Lucretius was at once an admired poet, a materialist attacked for not admitting divine involvement in the universe, and a philosopher who in fact had important things to say about living well. Even so, the alignment database allows us to see a handful of authors, mostly medical and scientific writers, whose views of Lucretius and his ideas veer from this basic narrative. Mainly toward the middle and latter parts of the century, some reuses suggest a less troubled acceptance of Lucretius's naturalism.

Through this presentation, we hope to show that this alignment database, through the accumulation of so many instances of citation, can facilitate a kind of large-scope reading that allows scholars to gain a nuanced sense of longer term intellectual trends. Built on a huge quantity of uncorrected OCR, the database provides scholars the specific source evidence -- and a ready means to access it -- that they might need as a starting point to pursue even deeper investigations into the thought of the 18th century.

What News is New?: Ads, Extras, and Viral Texts on the Nineteenth-Century Newspaper Page

Ryan Cordell
rccordell@gmail.com
Northeastern University, United States of America

David Smith
dasmiq@gmail.com
Northeastern University, United States of America

Newspapers became a truly mass medium in the nineteenth century due to the steam press, the post, the telegraph, and, especially in the U.S., mass political parties. Many scholars working on newspapers and other nineteenth-century media have noted the high level of "exchange" between different publications and the importance of understanding what was reprinted for understanding what readers and editors of the period valued (see, for instance, McGill, 2003; or Garvey, 2012).

In the first stages of the Viral Texts Project, we developed efficient clustering methods based on statistical language modeling and alignment to identify reprinted texts in digital archives of newspapers and magazines, beginning with the Chronicling America corpus and expanding to include papers from the UK, Australia, and Europe. Approaching the newspaper corpus through the lens of text reuse, Viral Texts has led to substantial insights into low-level problems of text reuse analysis in errorful OCR archives, higher-level network analysis of cultural circulation (Smith et al, 2015), the informational mode of nineteenth-century newspaper reprinting, the network effects of authorship in the nineteenth-century newspaper medium (Cordell, 2015), the circulation of popular "fugitive poetry" during the period (Cordell and Mullen, forthcoming 2017), the bibliographic implications of errorful OCR (Cordell, forthcoming 2017), among other things (project publications and press are available on the project site, and the project data sets are available on Github).

The computational methods of the Viral Texts Project produce a database view of the textual field. We read nineteenth-century newspaper snippets as "clusters" of reprints in a spreadsheet or database. We do not read them in the contexts of their original publications, but as disambiguated segments of text excerpted, aggregated, and listed. Such a database view is not *substantially* distinct from much older bibliographic views. The "clusters" of reprints generated by this algorithmic approach are still, essentially, enumerative bibliographies of textual snippets that circulated in nineteenth-century newspapers. Organized in a database, their appearance and presentation echo the conventions of printed bibliographies that list, for example, all known witnesses of a particular author's works.

Considering a text's bibliography allows us to speak of it in terms of circulation, audience, and influence, but the meanings of those corpus-scale phenomena are not evenly distributed among the witnesses that comprise its bibliography, when considered individually at the codex scale. Our current work seeks to map what we know of reprinting at a systemic level back onto the newspaper page, taking up the challenge in Matthew Philpott's recently articulated "understanding of the conceptual dimension of a periodical as a statistically self-similar, fractal form across all levels of scaling, from the periodical as a whole in its full publication run, to the year or annual volume, and down to the individual issue or number." (Philpotts, 2015) Likewise, what we are learning about disambiguated reprinted texts can help us understand the generic conventions and material operations of particular newspapers from our corpus over time, and to compare such features among papers.

Since developing our methods to detect reprints, project Ph.D. student Jonathan Fitzgerald has developed classification methods for sorting the millions of resultant clusters into meaningful categories: separating poetry from prose, for instance, or fiction from advertising testimonials and hard news (for discussion of some of this early classification work, see Fitzgerald, 2016). Building on Fitzgerald's classification work, we can now ask what generic trends we can spot within particular newspapers, or across the corpus. Some genres prove quite amenable to automatic classification, with success rates well over 90% for classifying advertisements and news and 84% for classifying poetry. Nineteenth century scholars and book historians, for instance, would expect to see poems in particular corners of the newspaper: the top left corner of page one in some papers, or the top left corner of page 4 in others. Drawing on tens of thousands of automatically identified poems, we can test those ideas more broadly, asking just how consistently the *Lewisburg Chronicle, and the West Branch Farmer* reproduced poems in the page one poetry corner, or just what percentage of papers chose one or the other of these two conventional placements. Perhaps more interestingly, we look for outliers in the data: newspapers that printed poetry in ways that defied generic norms, which may prove to be particularly interesting for periodicals and book historians.

Another structural aspect of periodicals addressed by this approach could be summed up with the question, "What news is new?" In short, while we know newspapers relied on reprinting and other kinds of textual recycling to fill column inches with limited staff, we can now compare habits of reuse within papers and among papers, asking for instance which newspapers relied more or less on reprinting—which were primarily producers or consumers of content—and how reprinted content populates the pages of particular newspapers. Again, we ask what patterns of new vs. reprinted content we can map across issues of particular papers, or how those patterns compare among different papers. Finally, we investigate how reprinted material migrates within particular newspapers over time; as stories age, can we trace them moving from page one through the latter pages of subsequent issues?

At an even finer level, we can ask how much total content was kept set up in type from one newspaper issue to the next. In the early and middle nineteenth century, many newspaper advertisements ran continuously for weeks or months at a time. Some advertisements even had short codes printed at the end for start date and duration, so that compositors could check whether an ad should be kept. In addition, news stories might be only slightly updated from day to day. By tracing this reuse among consecutive issues of the same newspaper, we can better estimate how much work by editors and compositors went into putting together the paper. We can also see how these practices changed over the course of the century as wire services and national advertising campaigns increased the freshness of newspaper content (figure 1). By illuminating precisely what text was kept in standing type, both in particular newspapers and comparatively across the corpus, we generate new insight into the workings of the nineteenth-century printing office, as well as the priorities and work habits of editors and other newspaper employees. Given the new internationalism of our corpus, we can also compare such practices across national and linguistic boundaries.

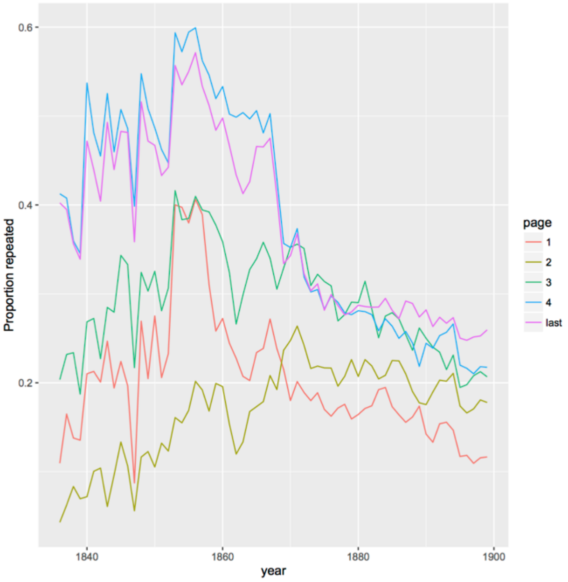

Figure 1: Average proportion of text on a page repeated from the previous issue of the same newspaper in the Chronicling America dataset, 1835–1900. Separate lines show reprint proportions on page 1, 2, 3, and 4. Through the early part of this historical period, most newspaper issues had four pages. A separate line shows reprint proportion on the last page, whatever it is. Repeated content is measured by globally aligning each page with all pages of previous issues in the last seven days.

For this paper, we build on the alignment and clustering methods developed in the Viral Texts project in two ways. First, by applying text categorization at the cluster level, we are able to make more robust inferences about genre than we would by scanning an individual newspaper page. Since each cluster of reprints preserves the location on the original page of each witness, we can then easily map these inferences back onto each issue. Second, we implement new, efficient global alignment algorithms to trace repeated ads, boilerplate, and news updates across successive issues of all newspapers in the corpus. We can prune the search space of this alignment algorithm more aggressively since texts kept in set type will retain the same line breaks, spelling errors, etc., as their previous printings. For robustness in the face of OCR errors, we align each issue to one or two weeks worth of previous issues. While global, linear (monotonic finite-state) alignment gives us promising initial results (see figure 1), we are also experimenting with greedy top-down inference that allows block moves of passages. Finally, we note that this procedure for detecting repeated passages across consecutive issues gives us yet more evidence about the boundaries of stories, which might not be typographically marked by, e.g., headline fonts.

These are just a few examples of how we are modeling the structure of newspaper layout and production. Such modeling allows us to test ideas about newspaper materiality advanced by scholars working with particular publications and ask new questions about both trends and outliers in the newspaper system of the nineteenth century.

Digital Humanities from Scratch: A Pedagogy-Driven Investigation of an In-Copyright Corpus

Brian Croxall
brian.croxall@brown.edu
Brown University, United States of America

Following the publication of Franco Moretti's *Graphs, Maps, Trees*, scholars looking to apply digital humanities methods to literature have increasingly been drawn to "distant reading." The influence of distant reading in digital humanities is apparent not only in the work it has inspired (see, among others, Cordell and Smith; Elson, Dames, and McKeown; Jockers; Long and So; Rhody; and Underwood) but also for its regular inclusion as a method in courses introducing DH. "Teaching digital humanities," it turns out, often means "teaching distant reading."

Teaching students the techniques of distant reading can be challenging as it depends on re-framing the familiar object of study. But another difficulty altogether is that this approach depends on a digitized corpus; and such a corpus, in turn, depends on someone, somewhere doing the difficult labor of digitization. One might ask, then: if "teaching digital humanities" means "teaching distant reading," shouldn't it also mean "teaching digitization"?

In this paper, I will discuss a collaborative, multi-year assignment that I conducted in two of my "Introduction to Digital Humanities" courses at Emory University: the digitization and analysis of the complete works of Ernest Hemingway (Croxall). With the goal of teaching my students not only how to do distant reading but also about the intense labor that goes into corpus preparation, we digitized the whole of Hemingway's work in just two weeks. Working from newly purchased copies of the texts, the students and I rapidly scanned hundreds of pages, performed and corrected optical character recognition, and assembled a corpus—with each of us spending no more than 4 hours on the task. Our from-scratch corpus was composed expressly so we could draw important distinctions among Hemingway's works: individual works vs the whole collection; fiction vs non-fiction; and works published before while Hemingway was alive vs those that appeared after his death in 1961. I will detail what we learned from rapid digitization and how those lessons affected the second iteration of the assignment.

After preparing the corpus, students worked in groups to analyze the many works of Hemingway that they had not had time to read. Making use of Voyant Tools, they identified themes in the corpus and charted patterns that could never have been observed through regular, close reading methods. For example, the class confirmed that while Hemingway insists on writing about "men," the women to whom they are attached are inevitably just "girls." In an attempt to chart the patterns of Hemingway's diction, another group of students investigated the terms he uses to introduce dialogue. Unsurprisingly, the students discovered that "said" is by far the most frequent such term across the entire corpus. What was more surprising, however, was to observe that in late and posthumous writings, the frequency of "said" suddenly drops by 50%. In short, by building our own corpus from scratch, the students were able to conduct original research, something that is relatively rare for many undergraduates in humanities programs.

Building our collection of texts from scratch had two critical advantages. First, we were able to create a small, relatively clean corpus whose provenance we knew. This provided a sense of confidence in the data as we began to distant read. Furthermore, while our analysis of Hemingway's works was "distant" compared to traditional close reading of a single novel or story, it was not nearly as distant as projects that deal with several thousand texts. We became engaged, in short, in close-distant reading. Second, digitizing the texts ourselves allowed us to skirt a problem that frequently plagues distant reading texts from the twentieth century: copyright. As an educational endeavor focused on teaching the students how to prepare their research materials, this guerilla digitization project fell under the regime of fair use in the United States.

To close, I will discuss how students at Brown University and I have taken further steps with the Hemingway corpus and with their digital humanities education as we have used it as a means to explore the methods and utility of topic modeling. Topic modeling is frequently deployed to come to terms with large and unwieldy corpora (see Jockers; Nelson; Nelson, Mimno, and Brown; Underwood and Goldstone). But working with a small, relatively clean corpus that is created from scratch allows students to better understand what takes place via unsupervised machine learning. At the same time, topic modeling allows us to ask in a new way some of the same questions that my former students had already uncovered: how does Hemingway's dialog differ from his prose? how different are the topics in Hemingway's fiction from those of his non-fiction? to what degree does his late—or even posthumous—work differ from what he wrote three decades earlier?

In the end, the process of modeling Hemingway becomes a means by which we can model all of digital humanities—both analysis and corpus creation—in a student-focused environment (see also Brier; Croxall and Singer; Harris; Hirsch; Jewell and Lorang; and Swafford). By doing digital humanities from scratch, students can be engaged in original research and see for themselves, from start to finish, how digital humanities gets done.

A World of Difference: Myths and misconceptions about the TEI

James C. Cummings
james.cummings@it.ox.ac.uk
University of Oxford, United Kingdom

Introduction

The Guidelines of the Text Encoding Initiative are generally recognised in the digital humanities as important and foundational standards for many types of research in the field. The Guidelines of the TEI are generalistic, seeking to enable the largest possible user base encoding digital texts for a wide range of purposes. Working on many TEI-based projects, teaching TEI workshops, and advising researchers on data modelling needs, I have encountered many misunderstandings about the TEI. Indeed, one keynote lecture (not at DH) once told me that "the problem with the TEI is it has too many tags and there is no way to change it". Inspired by myths like this, this paper will detail and expose common misconceptions about the TEI -- all of which have been espoused to me at some point -- but will concentrate on the more technical myths in a hope to increase knowledge about the TEI while dispelling some misconceptions along the way. Some of those to be investigated include:

"The TEI is too big (or complicated)"

While there is some truth to this -- the TEI Guidelines are numerous, consisting of around 565 elements -- no single project needs them all. Indeed, the TEI has mechanisms for customisation and recommends doing so to any project. The Guidelines themselves are modular and not all chapters will be appropriate or necessary to read for all projects.

"There is no way to change the TEI"

Although I have heard even well-respected keynote lecturers (not at DH) espouse this belief, it is patently and demonstrably false. This myth arises from unfamiliarity with the fact that the TEI is a framework entirely based on the concepts of adaptability and modification. Not only does the TEI have a sophisticated literate programming methodology to create meta-schemas which subset, constrain, and extend the vocabulary for any individual encoding project, but it also provides a variety of tools to enable users to do so.

"The TEI is too small (or doesn't have <my:SpecialElement>)"

While seemingly the opposite of #1, a frequent complaint made by those unfamiliar with the customization mechanisms of the TEI is that it does not have the special element needed for a particuar encoding project. There is, naturally, a reluctance to add new elements to one's customization -- and getting more generalized solutions into the TEI Guidelines themselves is indeed a better solution -- however, many new elements are added to the Guidelines through community development across disciplines. Any user is free to add <my:SpecialElement> but generally it is a better idea to get a number of individuals or a special interest group to agree a more detailed proposal.

"The TEI is XML (and XML is broken or dead)"

This idea is usually espoused by those who want to support some other, newer, format. Leaving aside the need some feel to denigrate one format in order to support another, XML is a widely supported format which will be with us for many years to come. However, TEI is **not** XML -- it is currently serialized as such, but previously it has been serialized as SGML, and in the future it may be expressed in another format(s). While there is currently no other widely adopted format which meets the many and varied needs of the TEI's central format, this does not mean that the TEI cannot be used with many other formats (as input, output, integrated with it).

"XML (and thus TEI) can't handle overlapping hierarchies"

Many people have discussed their concerns of overlapping hierarchies in XML, and while it is true that there are limitations in expressing multiple hierarchies in XML, it also has solutions built into it, such as empty elements to represent one or more alternative hierarchies. Primarily, this misunderstanding is also based on the assumption that all markup is embedded markup. The TEI Guidelines include a chapter on representing non-hierarchical structures, and the TEI framework has many features for representing fragmented element structures, out-of-line and stand-off markup, and the association of additional annotation through URI-based pointing. In addition, many DH text encoding projects only require two hierarchies (e.g. intellectual vs physical representations) and the TEI provides transformation solutions to alternate between these.

"You can't do stand-off markup in XML (or TEI)"

This myth shows a misunderstanding of both XML and the TEI. The former is a language for markup vocabularies and puts no restriction on whether that markup is embedded, out-of-line, or entirely stand-off. The TEI Guidelines provide a number of solutions entirely geared to stand-off markup, and its community is working towards introducing more features in this area. The combination of fine-grained markup, URI-based pointing and/or XPointer schemes, and descriptive markup designed to function this way, means that stand-off markup is supported in the TEI.

"You can't get from TEI to $myPreferredFormat"

One of the benefits of XML is that it is easily processable to other formats. The TEI Consortium provides around 40 conversions to/from other formats, including, for example: bibtex, cocoa, csv, docbook, docx, dtd, epub, html(5), xsl-fo, json, InDesign, latex, markdown, mediawiki, nlm, odd, pdf, rdf, relaxng, slides, txt, wordpress, xlsx, xsd, and many more. There exist RESTful web services like *OxGarage* which can provide a pipeline for these and other conversions.

"There are no tools that understand the TEI"

This is false -- thousands of TEI projects have created many tools which process, mine, convert, and visualize TEI data. While the TEI Wiki lists some of these, one of the problems is that projects do not necessarily advertise and openly share their tools. Much of the software developed by projects is also bespoke and specific -- they are not necessarily generalisable to other projects' needs. There are also many sophisticated encoding activities (such as stand-off markup) for which there are few general tools, since these are usually implemented in project-specific methods.

"If you create a TEI-based digital edition you must learn other $tech"

While historically it has been the case that to create TEI-based digital editions one must learn, or employ those who know, various technologies, this is increasingly less of an issue. Out of the box software like *eXist-db's TEI Publisher* and *TEI Boilerplate* mean researchers are able to publish digital editions for themselves. Moreover, the TEI has introduced implementation-agnostic methods for documentation of intended processing models in a TEI customization. This can then be used to generate project-specific code based on changes to the customization, as in the case of the eXist-db implementation of the TEI processing model. This new aspect of the TEI enables developers to write more generalized software which relies on the TEI ODD customization file for information on the processing model.

"TEI is only for Anglo/Western works"

There is much about the TEI Guidelines that is based in Anglo and Western European textual traditions, but the Guidelines also make an effort to enable use in other languages and cultures. The definitions and glosses of elements (etc.) can be viewed in a number of languages (English, German, Spanish, French, Italian, Japanese, Korean, Chinese). There is an entire internationalization framework built into the TEI Guidelines and the TEI Customization language, which means that the schemas can routinely display these internationalized definitions in editors and those creating customisations can have definitions, examples, and attribute value descriptions, in any Unicode-expressable language.

"Interoperability is impossible with the TEI"

Interoperability is a good and laudable goal, but the potential richness of TEI encoding for research and analysis purposes should not be sacrificed for this (depending on the point of the initial encoding project). While interoperability does suffer in a framework that is customizable and extendable (which are necessary for such a generalized system), it is certainly possible. Usually it is a process of crosswalks or some scripted transformation to a lowest common denominator that involves someone knowing both resources. The creation of sub-communities (such as the TEI subset EpiDoc), which agree encoding standards that are tighter than the necessarily general and flexible TEI, can improve this significantly.

"The TEI is only for digital edition(s)"

The TEI may be used for many forms of output, for example camera-ready copy. The primary mistake here is to assume a one-to-one relationship between TEI encoded files and a single particular output. If significant encoding has taken place, a wide variety of outputs are possible. If the format is used to its full potential, many aspects of an edition can be created, as well as supplementary files, indices, introductory material, interactive data visualizations, and more. The use of the TEI can also be used outside of edition-building, for the creation of linguistic corpora, digital facsimiles, and other resources.

Summary

While these are only some of the myths surrounding the TEI, discussing these will be beneficial to the DH audience, and will hopefully lead potential TEI users to question other "received wisdom" about the Guidelines.

A Common Conceptual Model for the Study of Poetry in the Digital Humanities

Mariana Curado Malta
mariana@iscap.ipp.pt
Instituto Politécnico do Porto, Portugal

Elena González-Blanco
egonzalezblanco@flog.uned.es
Universidad Nacional de Educación a Distancia, Spain

Clara Martínez Cantón
cimartinez@flog.uned.es
Universidad Nacional de Educación a Distancia, Spain

Gimena Del Rio
gdelrio.riande@gmail.com
CONICET, Argentina

Many of the DH approaches to poetry have focused on its metrical aspect (Birnbaum & Thorsen, 2015a, 2015b; Pue, Teal & Brown, 2015; González-Blanco, Martínez Cantón & Rio Riande, 2015). Following Chatman & Levin (1967, p. 142) we could say that meter is a "systematic literary convention whereby certain aspects of the phonology are organized for aesthetic purposes." In this sense, versification is an abstraction of linguistic phenomena in which words (in their formal and semantical aspect) relate to rhythm and rhyme for artistic purposes. Although many theories about versification and metrics have been developed for different languages and traditions, our work is interested in a structural and formal approach that looks at poetry into discrete units, categories, and their relationships. Thus, we are involved in analysing how metrical repertoires in digital form model those structures.

A digital repertoire of poetry metrics is a catalogue that gives account of the metrical and rhythmical schemes of either a poetical tradition, a period or school, gathering a corpus of poems that are defined and classified by their main characteristics. This kind of repertoires may sometimes contain the text of the poem and information related to authors, manuscripts, editions, music, and other features, all of them related to the poems. In the beginning, repertoires were printed books in which we could find information listed in a way similar to an address book. The digital era has changed the way in which information is displayed allowing the user to perform complex and multiple searches. In all these cases there is an ontological leap when the data is put in digital format.

There are a vast number of European digital metrical repertoires available online in open access – e.g. French lyrical collections (Nouveau Naetebus), Italian (BedT), Hungarian (RPHA), Medieval Latin (Corpus Rhythmorum Musicum, Annalecta Hymnica Digitalia), Classical Latin (Pedecerto), Galician-portuguese (Oxford Cantigas de Santa María, MedDB2), Castilian (ReMetCa), Dutch (Dutch Song Database), Occitan (BedT, Poèsie Neotroubadouresque, The last song of the Troubadours), Catalan (Repertori d'obres en vers), Skaldic (Skaldic Project), or German (Lyrik des Minnesänger), among many others. Each one of these metrical repertoires was developed in a specific technology and stores data in its own database. This data is locked in the information silos of each repertoire, not available freely to be compared and used by intelligent machines that could infer over the data. The lack of interoperability between the different digital repertoires dealing with poetry across different languages, literatures and traditions is a problem that needs to be addressed (González-Blanco & Seláf, 2014; González-Blanco, Rio Riande, Martínez Cantón & Martos Pérez, 2014; González-Blanco, E. G., Rio Riande, G.del & Martínez Cantón, C., 2016a). There is an interoperability problem since the technological solutions used for building the database of each digital repertoire employ a different data model.

POSTDATA is a project funded by a Starting Grant of the European Research Council whose main goal is to study European poetry in a comparative and wide context. Its starting point is the analysis of digital metrical repertoires as digital objects that have been developed to expose European poetry on the Web of Documents in open access. POSTDATA is an idea that resulted from previous work developed by a network of partners that own digital metrical repertoires and that have been working together for some years.

The POSTDATA project focuses mainly on the possibilities of Linked Open Data (LOD) technologies in order to publish the data available on information silos in the Web of Data as LOD. A side effect of this project is that not only this network will be able to publish its own data in LOD but also any other entity that owns data related to poetic metrics. Once the data is structured the same way and published in the Web of Data, anyone will be able to deploy new software that uses this data. It will be possible to compare, extrapolate and create new views of the data, opening doors to new knowledge in i) literary research communities since POSTDATA results will enable comparisons of poetic traditions and the creation of new repertoires, and ii) literature learning environments for e.g. the development of editorial projects following the common conceptual model.

LOD technologies are very powerful since one can implement intelligent agents to infer over the data (W3C, 2010). Another advantage of LOD over other paradigms is the infinite possibilities of linking data, allowing agents to rely also on other sources of information to build knowledge.

The first step of POSTDATA is the development of a Metadata Application Profile (MAP) for the community of practice of Digital Humanities that deal with poetry. An MAP is a semantic model, a construct that enhances interoperability (Nilsson, Baker, & Johnston, 2008).

The development of an MAP is a crucial task for any community of practice. This development should be structured, and has to integrate –since the early phases of development– elements of representative members of the community. Commonly the organizations of a community of practice differ in organization-type, location, culture and in the language they speak. In poetry studies, all these are key factors, since metrics and their features are based largely on the nature of the languages. In addition, in the case of the Digital Humanities Poetry metrics community, the way metrics has been conceptualised in the different traditions is however diverse, as there are multiple ways of encoding and understanding metrical systems. Finding a common ground of understanding in such an environment becomes a huge challenge. These digital metrical repertoires are the key to build an inclusive MAP for poetry, since they reflect different approaches of conceptualising poetry and their formal features.

POSTDATA is using Me4MAP, a method for the development of metadata application profiles (see Curado Malta & Baptista 2013a, 2013b), to develop the referred MAP. According to Me4MAP, the first activities in such a development are "S1 – Developing the Functional Requirements" and "S2 – Developing the Domain Model," these two activities result, respectively, in the Functional Requirements deliverable and in the Domain Model deliverable. S1 activity feeds S2 activity.

A Domain Model is a conceptual model that is used to explicit the concepts that exist in a certain universe of discourse. The concepts have properties to show how they are defined and related.

As described in Curado Malta, Centenera & Gonzalez-Blanco (2017), the work-team is developing the Domain Model at the same time S1 activities occur, slightly changing the order of S1 and S2. This change is possible since Me4MAP is also under evaluation and testing in a Design Science Research methodological approach –for more information about this process see Curado Malta (2014). This Me4MAP testing is leaded by one of the authors.

The goal of this paper is to present a preliminary version of the Domain Model of the MAP for Poetry – Domain Model V0.1. The following paragraphs give details on how this version of the Domain Model was developed.

The Domain model V0.1 was developed based on the analysis of eleven data models of databases of metrical repertoires (see Table 1) using a reverse engineering technique –for more details about this technique see Curado Malta et al. (2017).

Table 1. Repertoires which databases were used as basis for Domain Model V0.1

These repertoires have different technologies and paradigms: ten are in the Web of Documents and one is deployed locally. The technologies in which the databases are implemented are: 1) MySQL databases, 2) XML databases and files, 3) Perl scripts and, 4) Worksheet files.

The Domain Model of the MAP is represented as an Unified Modeling Language (UML) class diagram that expresses POSTDATA proposal for a common conceptual model for the European Poetry. The Domain Model V0.1 is available online (permanent link). The technique used to represent the domain model is UML since it is a standard technique (ISO/IEC 19505-1 and 19505-2) to model businesses and processes very well known in the software engineering community –see Rumbaugh, Jacobson and Booch (2004).

This first version will be tested in a Workshop held in March where partners of the project will follow a hands-on session to test the Domain Model V0.1 using a resource of its own database. POSTDATA will give to each partner a template testing sheet and information about the mapping between the database in question and the Domain Model. The conclusions of the testing and of other workshop discussions will feed the process of development of the Domain Model. The work-team programs to deliver a version 0.2 out of this worshop conclusions. This process of development is highly iterative; it will be fed by the following activities:

- development of S1 activities (as already referred before);
- Analysis of the results of a survey to final users: POSTDATA wants to know the needs of final users of repertoires in order to understand their problems and how they can be solved. Part of the survey is created based on the existent models. The survey also has open questions for users to fill in freely.
- Analysis of other poetic repertoires: there are still at least eleven databases' data models to be analysed. POSTDATA is still looking for more poetic repertoires in order to have a wider representation of other languages and traditions (plewease see the geographical view of the repertoires) Analysis of the information of two case studies: two researchers are building a digital repertoire at the same time the MAP is being developed; they will inform the workteam about their needs.

Once a stable version of the Domain Model is available, POSTDATA will follow the activities described by Me4MAP. One important activity is the mapping of the Domain Model to a semantic model, where every property of the Domain Model will be matched by an RDF vocabulary term, other constraints such as cardinality, domain and range must also be defined. In order to enhance interoperability, this matching has to be done taing care that the most popular vocabularies of the LOD ecosystem are used. A study of the most used vocabularies will be performed so as to find the best options for each term. Examples of RDF vocabularies that might be used are Dublin Core Metadata Terms, Digitised Manuscripts to Europeana (DM2E), Friend of a Friend (FOAF) vocabularies, among others. This semantic model will be tested in an iterative process of development, using resources from metrical repertoires that were not used as cases in the metadata application profile process development.

Vers les Données Liées : Conséquences Théoriques et Pratiques Pour les Sciences Humaines

Lyne Da Sylva
lyne.da.sylva@umontreal.ca
Université de Montréal, Canada

Introduction

Le Web ne sera peut-être jamais plus comme on le connaît maintenant. Ce vaste répertoire de connaissances et informations publiées et commentées par les internautes risque, si la tendance des travaux du W3C se maintient, de s'enrichir d'une couche de représentation supplémentaire. Le Web sémantique et les données liées ne visent pas à remplacer le Web existant, mais à s'y greffer. Ils représentent un nouveau paradigme de représentation de l'information sur le Web, non plus comme des documents cohérents (des pages Web lisibles par l'humain), mais plutôt comme des jeux de données (Linked Open Data) représentant des relations binaires entre un objet et une propriété de celui-ci : des « triplets », encodés selon des standards précis et permettant des traitements automatiques à grande échelle. À la place du Web existant, ou en complément de celui-ci, le Web de données ouvre de multiples possibilités de mise en rapport d'informations diverses. Il fait miroiter des possibilités de recherches d'information plus élaborées (parce que basées sur des ensembles d'inférences éventuellement complexes) et de traitements automatiques sophistiqués sur les données.

Tout ceci est sans doute vrai; plusieurs membres de la communauté scientifique et de diverses communautés professionnelles ont déjà contribué à construire le désormais gigantesque réseau Linked Open Data (Europeana, OCLC, Library of Congress, ACM, BBC Music,...).

L'objectif de cette communication n'est pas de remettre en question le processus, mais bien de poser un regard éclairé sur certaines des conséquences de ce passage des documents aux données liées pour les sciences humaines.

Brève description du Web sémantique et des données liées

Le Web sémantique repose de manière importante sur l 'identification et la description d'entités : les entités dignes d'importance, dans les représentations du Web sémantique, incluent toute entité sur laquelle on peut vouloir exprimer des propriétés ou relations. Ces entités peuvent être des ressources présentes sur le Web (des sites web, des bases de données, etc.) ou non : des personnes en chair et en os, des livres imprimés, des sites géographiques, archéologiques, touristiques, etc. Ou toute autre entité abstraite comme une date, une couleur, un rite funéraire, etc.

Nous présenterons les éléments de base du Web de données : les identifiants (URI) qui représentent les entités, les relations de diverses natures qui permettent de relier les entités, les triplets RDF qui servent à encoder les relations entre entités, les vocabulaires et ontologies qui permettent des descriptions uniformisées, les triplestores qui emmagasinent les jeux de triplets RDF.

Nous soulignerons également les avantages de l'utilisation de données liées en sciences humaines, en illustrant à l'aide de quelques projets de recherche récents (en histoire : Michon, 2016; en littérature : RDA, 2015; en musique : Cannam et al, 2011)

Conséquences pratiques

Suite à cette brève présentation, nous examinerons d'abord les conséquences pratiques du passage aux données liées pour les sciences humaines. Celui-ci influe premièrement sur le focus de la recherche, qui se fait alors graduellement vers l'information et non le document (processus antinomique à certaines disciplines en sciences humaines). Deuxièmement, le travail nécessaire à l'extraction des données est considérable, contrairement à ce qui est de mise en sciences pures (où une partie de l'encodage des données liées est fait à partir de données discrètes obtenues par des appareils de mesure : sondes océanographiques, lectures géologiques, observations astronomiques). Troisièmement, nous verrons que cette transformation rappelle la notion de « redocumentarisation » déjà observée pour le document numérique (Pédauque, 2007). Le terme est utilisé pour décrire les bouleversements induits par l'apparition du document numérique; l'encodage des données dans les technologies du Web sémantique exige d'extraire l'information encodée dans des documents existants et de l'exprimer dans un nouveau format. La création de chaque triplet nécessite un travail d'analyse fine des documents et la décomposition en ses unités élémentaires. On parlera ici de l'atomisation de l'information contenue dans les documents, qui a également des conséquences théoriques (voir ci-dessous). Mais les conséquences pratiques sont déjà considérables.

Conséquences théoriques

Les conséquences théoriques du passage au Web de données touchent d'abord la nature des objets de l'étude. En premier lieu, nous aborderons la réification des éléments d'information : tout énoncé (triplet RDF) destiné au Web de données requiert (i) que l'entité à décrire soit définie ontologiquement dans l'univers de référence (le vocabulaire ou l'ontologie); (ii) que l'entité qui lui est reliée reçoive le même traitement (même lorsqu'il s'agit de concepts abstraits comme la couleur d'un objet); et (iii) que la relation entre les deux entités soit elle aussi réifiée. La réification des deux entités ne choquera pas le chercheur, habitué à scruter l'essence des concepts qu'il étudie. Mais la réification de la relation – l'élévation au rang de concept de tout type de relation comme « est l'auteur de » ou « a correspondu avec » – changera sans doute de manière considérable la vision que le chercheur aura de cette relation.

Une deuxième conséquence théorique du passage au Web de données est le fait que la distinction entre données et métadonnées devient floue, voire inutile. Par le biais de l'extraction de données à partir de documents primaires, tout ce qui est encodé devient métadonnée. Mais si tout est métadonnée, de quelles données sont-elles les métadonnées? Les données disparaissent-elles? ou est-ce plutôt le concept de métadonnées qui disparaît?

Nous discuterons également de l'uniformisation exigée par les vocabulaires (ou référentiels) partagés. Si les vocabulaires sont davantage stables dans les sciences dites exactes, la terminologie fait moins consensus en sciences humaines et sociales (ceci a été largement documenté dans la construction de thésaurus documentaires). On peut s'attendre à un plus grand nombre de référentiels concurrents. Il est possible que le travail sur les ontologies ait un effet important sur la définition des concepts de base des disciplines et les tentatives de rapprochement entre disciplines. Les travaux en terminologie et en conception de thésaurus pourraient être mis à contribution dans l'entreprise. D'un autre côté, le fait que les données soient liées permet des interconnexions (et un potentiel de normalisation) qui n 'est pas requis lorsque les recherches se font davantage en parallèle.

Enfin, nous présenterons la notion de l'atomisation des objets de recherche. L'apport intellectuel des chercheurs en sciences humains est le résultat d'un travail d'analyse, de mise en rapport, d'abstraction à partir de données disséminées (documents historiques, phénomènes linguistiques, observations sur le terrain …). Or ces documents sont des créations, des synthèses, exprimant des idées réunies par l'auteur en propositions, en phrases, en paragraphes cohérents. À partir du moment où ces informations sont atomisées pour le Web de données, ce travail d'analyse est (potentiellement) perdu, disséminé dans les simples triplets. On peut avancer qu'au contraire, les relations identifiées par les chercheurs, et exprimées par les documents résultants, peuvent faire partie des relations exprimées par les triplets RDF. Mais on doit bien prendre conscience du fait que chaque énoncé reste, dans le formalisme, isolé des autres. Reste aux chercheurs futurs la tâche de développer des moyens de faire des abstractions additionnelles (à un niveau plus macro) à partir des simples triplets RDF.

Conclusion

Le passage au Web de données peut être extrêmement utile à la recherche en sciences humaines. Nous présenterons un certain nombre de conséquences pratiques et théoriques de cette mutation. Le passage aux données implique l'atomisation du sujet de recherche et la redocumentarisation de sa matière première, qui exige un travail important d'extraction d'informations et de réencodage. Il a comme conséquence la réification de chaque élément d'information inclus dans la nouvelle description. Les représentations résultantes brouillent la frontière entre métadonnées et données. Enfin, le passage aux données liées entraînera un partage des référentiels, un potentiel de plus grande interopérabilité entre les descriptions et, peut-être, une injection de travaux sur les concepts fondamentaux des disciplines, de pair avec des travaux en terminologie et en vocabulaires contrôlés. Il est important pour les chercheurs en sciences humaines de mesurer l'apport potentiel du Web de données et les transformations qu'il pourra apporter au développement de leur science ; la présente communication veut amorcer la réflexion sur le sujet.

Numbers into Notes: digital prototyping as close reading of Ada Lovelace’s ‘Note A’

Lovelace and Babbage

Ada Lovelace is widely held to be the first computer programmer, composing the first algorithm designed for execution by a general purpose computing machine. The algorithm was published in the “notes by the translator”, appended to her translation of Menebrea’s 1842 French account of Charles Babbage’s 1840 seminar on his proposed steam-powered computer, the Analytical Engine, at the University of Turin (Lovelace, 1842).

This third-remove contribution appearing in small print after the main article belies both the closeness of her friendship with Babbage and how extraordinary her vision was of what such a general purpose computing machine could achieve. The phrase often quoted in the literature of computers and music offers another insight into her imaginative response to the hypothetical Analytical Engine:

“Supposing, for instance, that the fundamental relations of pitched sounds in the science of harmony and of musical composition were susceptible of such expression and adaptations, the engine might compose elaborate and scientific pieces of music of any degree of complexity or extent.” (Note A)

Our work described in this paper explores this observation, taking inspiration both from Lovelace’s ideas and from composer Emily Howard’s creative response to them. Using digital technologies, we have prototyped software and hardware to investigate Lovelace’s theory of creative computing. We developed a web-based tool, Numbers into Notes, which we used as a prompt to engage the public with these ideas at live musical performances. The musical outcomes of our research are recorded as Digital Music Objects (De Roure, 2016a) which include provenance records.

Following Galey and Ruecker, we suggest that this application can be viewed as a designed digital artefact analogous to a critical work, explicating our interpretation of Lovelace’s words (Galey, 2010).

Simulator

Babbage’s Analytical Engine remains unconstructed, but today we can simulate the execution of programs on it digitally, based on the detailed accounts of the Engine’s design provided by Babbage and Lovelace. As an experiment in hearing what Lovelace might have imagined, we coded an algorithm to run on a simulator in order to generate number sequences which are then mapped to instruments. The numbers are strictly faithful to nineteenth-century mathematics. Human intervention decides the algorithmic parameters and the mapping of the numbers to notes and instruments, to be explored based on the musical context of the time. This experiment led to the creation of the Numbers into Notes web site, making the tools available to others for investigation and composition.

Performance

Emily Howard has also responded creatively to Note A, and the life of Lovelace, in composing her *Lovelace Trilogy* (Petri-Preis, 2013). ‘Ada sketches’ is a short operatic work for mezzo-soprano, flute, clarinet and percussion. Howard’s time as Composer in Residence at the University of Liverpool’s Department of Mathematics, and her work there with Lasse Rempe-Gillen, led to this piece which has been performed in formats that encourage audience response and participation. A performance at the University of Oxford as part of celebrations to mark Lovelace’s 200th birthday investigated the audience’s reception of the work. Its most recent performance, at the Royal Northern College of Music, used our Numbers into Notes web application.

Digital–physical

The Numbers into Notes software invites a thought experiment: had Lovelace lived longer, and had Babbage successfully built the Analytical Engine, what might have happened in pursuit of Lovelace’s musical observation? We extended this thought experiment to ask “what might Lovelace do today?” To explore this, we constructed multiple physical devices (based on the Arduino open-source electronic prototyping platform) to re-enact the algorithms designed for the Analytical Engine (De Roure, 2016b). Today Lovelace could combine multiple machines, and the computational power would enable real-time synthesis, putting into practice the mathematical notions of consonance that were established in the eighteenth century.

Experimental humanities

This approach, which we suggest might be framed as *experimental humanities*, has attracted engagement during events and online, and has also been a successful vehicle in teaching (in the Social Humanities strand of the Digital Humanities at Oxford Summer School). Our work uses digital tools, co-designing digital and digital-physical artefacts, to explore and re-imagine prospective and theoretical technologies of Lovelace’s day. Through this we provoke new responses and discoveries relating to music practice and performance, and to the philosophy and history of technology. The practice of this *experimental humanities* approach enables critical reflection and re-interpretation: we suggest that the digital artefacts we have produced are each interpretations drawing on the life and writing of Lovelace, and the value of this practice lies in the new insights and works they inspire.

This paper recounts these experiments that play at once into generative design and into alternative histories of algorithms and mechanisms. Through making, through prototyping and co-design, we close-read the thought processes Lovelace and Babbage recorded. We point to paths in the development of computing and programming that were not taken, and extend beyond what was practicable in the nineteenth century. Our work also touches on creativity, as anticipated by Lovelace and recast in the "Lovelace questions" (Boden, 1990), and manifest today in the fields of computational creativity and creative computing.

A Capacity Building Framework for Institutional Digital Humanities Support

Quinn Dombrowski

Coalition for Networked Information
United States of America

The development of well-known institutional digital humanities programs-- such as those at the University of Virginia, University of Victoria, University of Maryland, and others -- has been significantly influenced by unique combinations of dynamic individuals and receptive institutional circumstances. Faculty and administrators in leadership positions at a growing number of universities are interested in developing some form of institutional support for digital humanities research and/or pedagogical practices, but are starting with a fragmented local landscape. Where previous work has focused on particular facets of successful digital humanities programs (e.g. organizational models in Maron & Pickle 2014), addressed digital humanities within a particular organizational context (e.g. in libraries, Varner & Hswe 2016 and Schaffner & Erway 2014) or provided case studies from a single institution (Maron 2011), to date there has not been a holistic framework that can serve as a guide for improving institutional support.

In spring 2016, the EDUCAUSE Center for Analysis and Research (ECAR) and the Coalition for Networked Information (CNI) convened a working group of fifteen library and IT professionals representing a wide range of institution types in the US and Canada, with the goal of developing a "maturity framework" for institutions that are either getting started on developing a digital humanities support program/center or striving make additional progress with their existing efforts. While the maturity framework model is commonly used in ECAR working group publications to describe the adoption or implementation of new technologies or methodologies, particularly in an IT context, the working group quickly reached a unified decision that "maturity" was the wrong model for the development of a digital humanities program. Instead, the working group adopted a similar structure -- using defined stages of development across multiple parameters-- and termed it a "capacity building framework", in order to acknowledge that different institutions may prioritize different kinds of capacity, and those choices have little bearing on the “maturity” of the program as a whole.

The working group’s recently-published white paper identifies five major facets of developing institutional support for digital humanities, and characterizes for each one three stages in the development of institutional digital humanities support: early, established and high capacity. The paper acknowledges that different institution types, and even individual institutions, will choose different areas to prioritize, and there is no “one-size-fits-all” recommendation.

1. **Governance** -- how, and at what level(s), are decisions made? At the early stage, there is no governance in place beyond the individual project level. As a result, individual projects or courses flourish, or fail to do so, largely based on individual PIs’ personal connections and ability to secure funding and resources. For well-connected and charismatic scholars, the early stage may seem like the ideal one, as there are no systems in place to impede them from making any technical decision that suits them, and involving as many support staff as they can convince to participate. While the early stage model may be conducive to individual project capacity, given a particular kind of PI, it does little to build capacity at the institutional level. The white paper takes the position that governance is an important aspect of institutional capacity-building, by providing structures for transparent decision-making that apply equally to all projects. Depending on the institution, governance structures may be in place to determine allocation of internal grant funding or consulting resources, coordinate the purchase of software licenses or expensive hardware, and/or provide input into larger decisions in program development (e.g. whether or how to offer degree programs, whether to participate in consortial efforts to develop infrastructure or training programs, etc.)

2. **Infrastructure** -- providing access to both technology and expertise -- sits at the core of institutional support programs for digital humanities. The specific tools and resources provided can vary across institutions, depending on the needs and interests of researchers and instructors, as well as the particular skills and expertise of those providing support. The white paper notes that the effectiveness of technical infrastructure is contingent upon the availability of experts who can help scholars make use of that technology. While this is especially true for resources that have a high barrier to entry (such as high performance computing clusters), it also applies to software (e.g. for GIS, 3D modeling, text analysis, and OCR) and more prosaic infrastructure such as web hosting.

3. **Roles and Capabilities** -- successful digital humanities work is most often conducted in teams, with roles and capabilities from three complementary categories: technical experts, champions of engagement, and content innovators. Within these broad categories, there is great deal of overlap and interdependence; and it is through the overlap of roles and interdependence of capabilities that DH can flourish. Depending on the organizational model in place, projects may draw upon skilled collaborators at various places within an institution (e.g. museums and archives, central IT units) or even at other institutions through consortial agreements.

4. **Communication and Outreach** -- in the early stage of institutional support for digital humanities, individual practitioners are not aware of one another, and there are no established channels for disseminating news and announcements about events, workshops, grants, and other opportunities relevant to digital humanities. As institutional support becomes established, digital humanities mailing lists and event calendars are created, funding is accessible for one-off events and activities, and beginner-oriented training becomes available. High capacity for communications and outreach involves coordinated, regular communication, dedicated funding for activities, and multiple levels of training covering a range of skills.

5. **Acceptance** -- i.e. the acceptance of digital humanities work as a component of promotion and tenure, of course assessment, and of performance reviews for librarians and IT staff. The white paper notes that academic acceptance of digital humanities work is significantly influenced by developments within particular disciplines, for example, the development of guidelines such as those produced by the Modern Language Association (2012), American Historical Association (2015), and College Art Association (2016) for evaluating digital humanities scholarship. Nonetheless, an institution can increase its capacity at the local level by having department chairs, deans and provosts publicly take a position supporting the assessment of digital scholarship as part of tenure dossiers and advocate for the consistent application of disciplinary guidelines, where available. Acceptance of digital humanities also applies to the evaluation of courses with digital humanities components, as well as to performance evaluations for librarians and staff who support digital humanities work. In the early stage, librarians and IT staff provide digital humanities

> support “on the margins” of their jobs, whereas at a higher-capacity stage, digital humanities support is an officially recognized aspect of IT staff and librarians’ job descriptions, and is factored into performance evaluations accordingly.

To complement the capacity building framework, the white paper includes a section on getting started with developing institutional capacity. This section has pointers for how to do an environmental scan and needs assessment, a discussion of interdisciplinarity, recommendations for the kinds of partnerships that support institutional capacity-building, and a number of commonly-used organizational models.

Corpora and Complex Networks as Cultural Critique: Investigating Race and Gender Bias in Graphic Narratives

Alexander Dunst
dunset@mail.upb.de
University of Paderborn, Germany

Rita Hartel
rst@uni-paderborn.de
University of Paderborn, Germany

Introduction

This paper reports on efforts to integrate cultural critique into a DH project that analyzes a corpus of book-length comics, or graphic narratives. We argue that the analysis of issues such as gender, race, and class should be central to digital scholarship that aims to become accessible to the public and appear relevant to the humanities at large. Therefore, cultural criticism needs to be integrated into digital projects from the very beginning. Our research takes up calls to “design for difference” and to develop visualizations that “enact [the] humanistic properties” of complexity and contradiction (McPherson and Drucker, 242). Part I looks at the construction of a corpus of graphic novels, memoirs, and non-fiction. Basing our corpus on academic databases, international comics awards, literary histories, and online booksellers provides insight into institutional gender and racial biases, as well as the opportunity to address them. Part II takes up Drucker’s criticism of network analysis as reductive and static. We present networks of a pilot corpus that pay attention to social inequality and replace reductive edges with distinct forms of communication. Part II exemplifies our intention to make DH scholarship relevant to a wider public. The broad appeal of comics presents an ideal point of entry for people who might not otherwise be interested in digital research. We apply the popular Bechdel Test (proposed by Alison Bechdel in a comic strip but used mainly to study film and TV), to highlight the male bias of graphic narratives.

Corpus Analysis of Institutional Gender and Racial Bias

The traditional canon of literary studies has long been criticized for its exclusion of female, non-Western, and minority authors. As a much younger field, comics studies lacks the extensive canons and bibliographies produced by literary historians. This does not mean that similar biases are absent, however. As part of a larger project, we have built a monitor corpus of book-length comics by drawing on sources that include academic databases (JSTOR, MLA), international comics awards, literary and cultural histories of comics, news media coverage, and Amazon.com (Dunst et al.). Of 220 titles included in the corpus by fall 2016, 84 per cent were written by male authors and 73 per cent were identified as white. Biases are unevenly distributed:

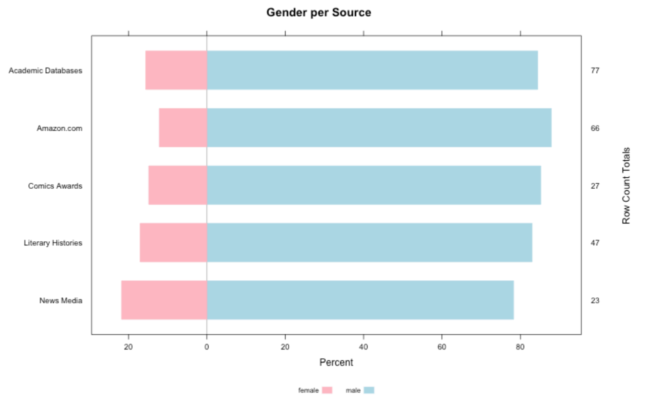

Figure 1: Gender of issue's author grouped by book's source

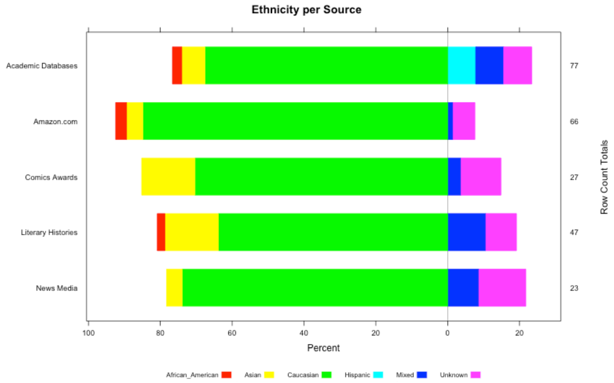

Figure 2: Ethnicity of issue's author grouped by book's source

The absence of reliable bibliographies means that the size, gender and racial make-up of the population remains uncertain. Yet given the considerable differences between sources, institutional biases appear likely. To address these existing biases, two steps were undertaken. A survey sent to comics scholars (five female, five male) asked them to suggest between five and ten graphic narratives written by women that should be included in the corpus. Of a total of 53 suggestions by nine respondents, nine volumes were listed by more than one scholar and 12 had already been included in the corpus, while 14 fell outside of the sampling frame. 16 new works were added, bringing the ratio of female author to slightly less than 22 per cent. The second step includes a comparison of the monitor corpus and collections held at the Library of Congress and the Billy Ireland Cartoon Library at Ohio State University. By checking authors in these collections against a list of names that were assigned genders by the US Social Security Administration, we compare their gender make-ups and will potentially add to our corpus.

Gender and Interaction Types in Semi-Automatic Networks

Network analysis has steadily grown as an area of research since Franco Moretti's visualization of Shakespeare's *Hamlet* (Moretti). Scholars have focused on automatic extraction and statistical analysis of data from novels, plays, and intellectual networks (Elson, Dames & McKeown; van de Camp & van den Bosch). Recent efforts include computing main characters and operationalizing dynamic networks (Jannidis et al; Karsdorp & van den Bosch; Xanthos et al). While these networks answer some of Drucker's criticism, the approaches remain reductive. Limiting interactions to undifferentiated edges appears particularly unsatisfying for visual media, in which communication takes visibly different forms: characters may look at and touch each other, or appear together in a panel. Despite recent advances, computer vision has trouble recognizing non-perspectival drawings and applying OCR to handwritten comics fonts remains fraught with difficulty (Dunst et al; Rigaud 2013 & 2015). As the automatic extraction of network data is some way off for comics, we focus on networks that are semantically enriched via manual annotation to engage with the central questions posed by cultural studies. The following network (Figure 3) of Karasik and Mazzuchelli's *City of Glass* combines different types of interaction with gender assignations:

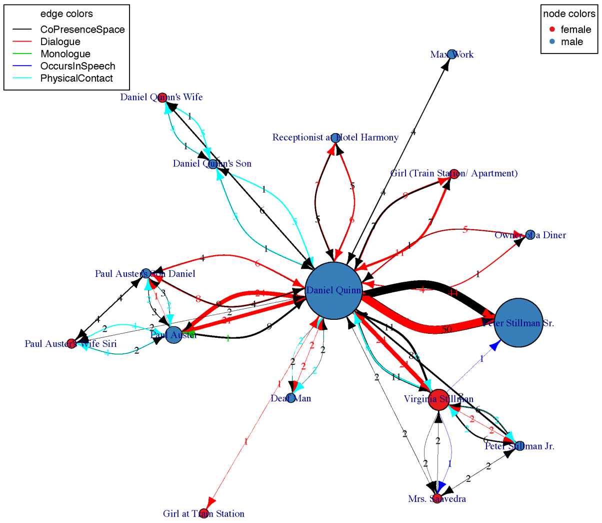

Figure 3: Interactions and gender assignations in *City of Glass*

These networks and the SSA name database allow us to study the relation between authors' gender and its fictional representation. Male characters are consistently more central to works by male authors. Notably, female characters show higher betweenness centrality in narratives written by women, as Figure 4 shows.

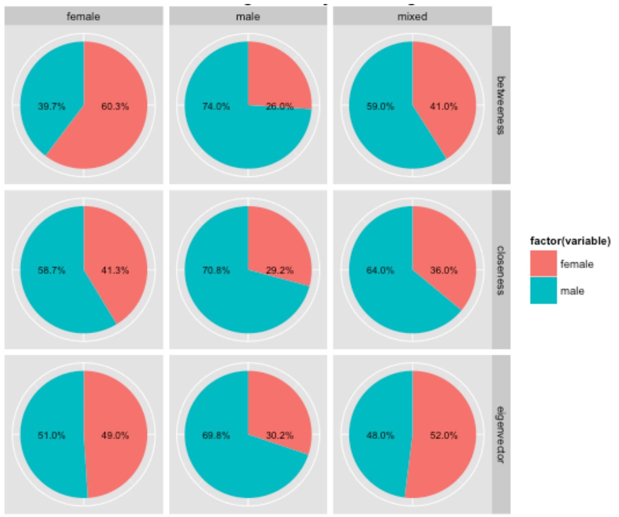

Figure 4: Centralities of character's genders by author's gender

Semi-Automated Bechdel-Test for GNML-Annotated Graphic Narratives

Efforts to automate the Bechdel Test have been limited to plays and film scripts and led to poor results (Lawrence; Agarwal et al). Three conditions need to be met to pass the test: 1. At least two female characters appear in the story. 2. There is at least one conversation between women. 3. The conversation is **not** about a man. Our XML-annotation language GNML, an extension of John Walsh's CBML, allows for automatically checking if graphic narratives fail criteria 1 and 2, and aids evaluation of whether the remaining narratives pass criteria 3. We decided not to rely on error-prone full automation but to use semi-automatic processes that aid human annotators/analyzers in retrieving quality results. GNML annotations contain information on all character occurrences, the gender of a character, and their interactions. As discussed by Agarwal, even sophisticated machine learning approaches lead to unreliable results in deciding whether a conversation centers on a man. Therefore, for criteria 3, we simplify decision-making by providing the annotator with a ranked list of dialogues, based on the number of male names or male personal pronouns per conversation. Significantly, even if a conversation's focus on a male character could be identified automatically, the test would still be error-prone. Conversations may span several panels or pages and automatic separation of these conversations remains difficult

Conclusions and Future Research

We present corpus metadata and semantically-enriched networks of a widely popular but understudied medium that is only beginning to attract attention by DH researchers. These methods are used to analyze gender and racial biases and suggest ways in which DH can appeal to scholars in cultural studies and the wider public. Future work includes expanding pilot studies to cover our entire corpus by integrating advances in OCR and computer vision and thus working towards fully-automatic extraction and analysis. In the meantime, our networks may function as conceptual models exploring how humanistic forms of complexity can be introduced into network analysis. Analyzing and addressing racial biases against minority authors presents hurdles of a different sort. A repeat of our survey for minority authors appears unproblematic but assigning racial identity to names or authors could be viewed as unethical and, given the international nature of our corpus, would have to consider the complex relationship of racial, national, and regional identities.

Short samples in authorship attribution: a new approach

Maciej Eder
maciejeder@gmail.com
Institute of Polish Language
Polish Academy of Sciences, Poland

Introduction

The question of minimal sample size is one of the most important issues in stylometry and non-traditional authorship attribution. In the last decade or so, a few studies concerning different aspects of scalability in stylometry have been published (Zhao and Zobel, 2005; Hirst and Feiguina, 2007; Stamatatos, 2008; Koppel et al., 2009; Mikros, 2009; Luyckx and Daelemans, 2011), but the question has not been answered comprehensively. In his recent study, Eder proposed a systematic approach to solve the problem in a series of experiments, claiming that a sample should have at least 5,000 running words to be attributable (Eder, 2015).

The above studies (and many other as well) tacitly assume that there exists a certain amount of linguistic data that allows for reliable authorial recognition, and the real problem at stake is to determine that very value. However, one can assume that the authorial fingerprint is not distributed evenly in a collection of texts. Just the contrary, many experiments seem to suggest that the authorial voice is sometimes overshadowed by other signals, such as genre, gender, chronology, or translation. Some authors, say Chandler, should be easily attributable, while some other authors, say Virginia Woolf, will probably have their fingerprint somewhat hidden. Moreover, authorship attribution is ultimately a matter of context: telling apart Hemingway and Dickens will always be easier than distinguishing the Bronte sisters. On theoretical grounds, then, the minimal sample size can not be determined once and forever for the entire corpus, but may be different for different texts in the corpus.

Method and Data

To scrutinize the above intuition, a controlled experiment has been designed, in which particular text samples were assessed independently (one by one) and compared against the corpus. A following procedure was applied: the entire corpus served as a training set, out of which one text at a time was excluded. This temporarily excluded text was further pre-processed: in many iterations, longer and longer samples of randomly chosen words were excerpted (100 independent samples in each iteration), and then tested against the training set. In each iteration, the total number of correctly “guessed” authorial classes – a single value between 0 and 100 – was recorded, resulting in a row of accuracy scores for a given text as a function of its sample size. The same procedure was repeated for each text in the corpus. The above setup does not need to be supplemented by any cross-validation, because the experiment itself is a variant of a leave-one-out cross-validation scenario. Moreover, each text is re-sampled several times, which can be perceived as an additional way of neutralizing potential model overfitting.

The experiments were repeated a few times. Firstly, three different classification methods have been tested: Support Vector Machines (SVM), Nearest Shrunken Centroids (NSC), and a distance-based learner that is routinely used in authorship attribution tests, namely Burrows’s Delta (Burrows, 2002). However, Delta was used as a general classification framework combined with a few custom kernels that seem to outperform the original setup. These included Cosine Delta (Evert et al., 2016), min-max measure (Kestemont et al., 2016), Eder’s Delta (Eder et al., 2016), and, obviously, the original measure as introduced by Burrows and mathematically justified by Argamon (2011). Secondly, all the tests have been repeated for different vectors of input features, or most frequent words: 100, 200, 300, 500, 750 and 1,000. While the choice of the vectors’ lengths was arbitrary, it was aimed to follow usual stylometric scenarios in their various flavors, ranging from a considerably short list of mostly frequent words, to a longish vectors overwhelmed by content words.

The aforementioned method of testing was applied into two roughly similar corpora (one at a time): a corpus of 100 English novels by 33 authors (male and female), covering the years 1840–1940, and a similar corpus of 100 Polish novels. Both corpora, referred to as the Benchmark Corpus of English and the Benchmark Corpus of Polish, have been compiled by Jan Rybicki (pers. comm.). The corpora used in the experiment, as well as the complete code needed to replicate the study, will be available in a GitHub repository.

Results

A lion’s share of tested samples revealed a very consistent and clear picture. According to intuition, the performance for short samples falls far beyond any acceptance rate, sometimes showing no correct “guesses” at all. This is followed, however, by a very steep increase of performance which immediately turns into a plateau of statistical saturation, despite the number of analyzed features (frequent words). An example of such a behavior is *The Ambassadors* by Henry James (Figure 1), as well as many other novels by Blackmore, Chesterton, Foster, Lytton, Meredith, Morris, Thackeray, and Trollope. As one can see, the amount of text needed for a reliable attribution is less than 2,000 words (!), an amount radically smaller than the previous study suggests (Eder, 2015). Sometimes the picture is somewhat blurry, nevertheless the same general shape reappears, as in the case of *Felix Holt* by

George Elliot (Figure 2). As one can see, using shorter vectors of features requires longer samples to extract the authorial profile.

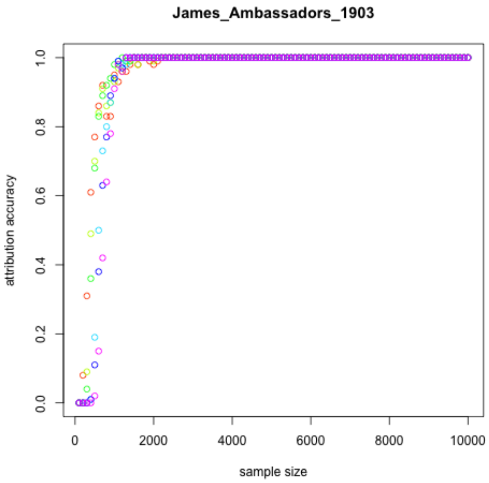

Figure 1: *The Ambassadors* by Henry James contrasted against a corpus of 100 English novels: the attribution accuracy as a function of sample size (in words). Colors represent the results for different vectors of MFWs: 100 (red), 200 (yellow), 300 (green), 500 (cyan), 750 (blue), and 1,000 (violet).

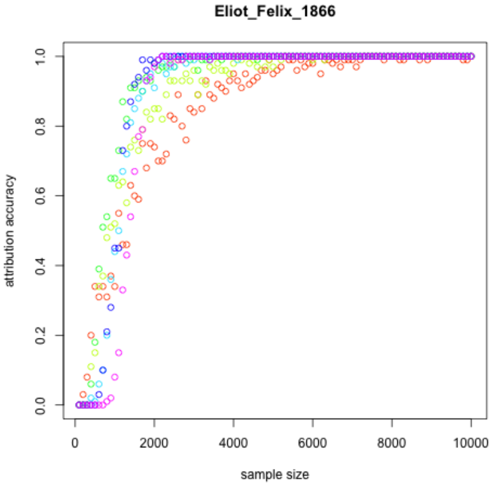

Figure 2: *Felix Holt* by George Eliot: the dependence of authorship recognition and sample size.

Optimistic as they are, however, the results might differ significantly. E.g., in some cases, the statistical saturation does not really take place, even if very long samples are used (Figure 3: scores for *Saints Progress* by John Galsworthy). What is more important, however, the final results additionally depend on the number of analyzed features. In Figure 4, a representative example of this behavior has been shown, namely *Bleak House* by Dickens.

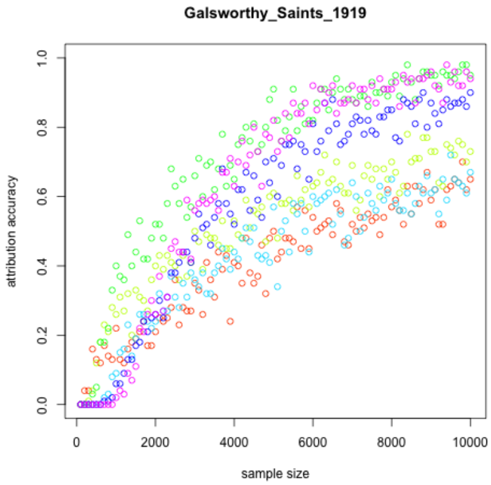

Figure 3: *Saints Progress* by John Galsworthy: the dependence of authorship recognition and sample size.

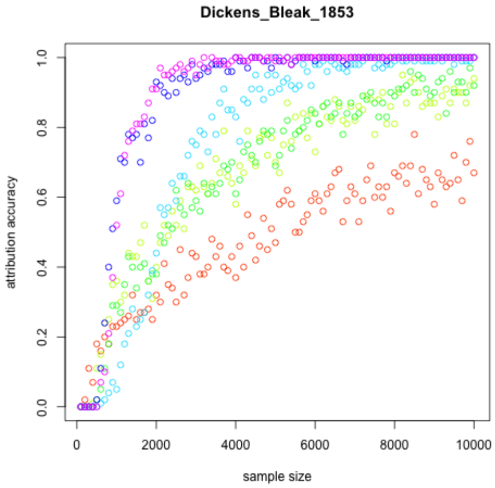

Figure 4: *Bleak House* by Charles Dickens: the dependence of authorship recognition and sample size.

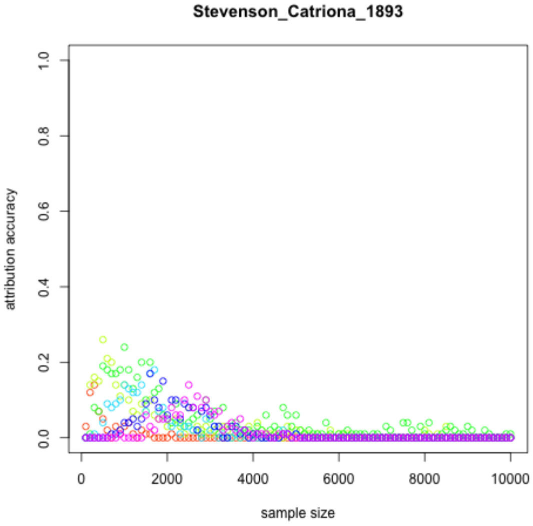

Figure 5: *Catriona* by Robert Louis Stevenson: the dependence of authorship recognition and sample size.

Last but definitely not least, there are a few texts that are never correctly attributed, no matter how long the extracted samples are (Figure 5). The question why some novels were misclassified will be addressed in a separate study. Here, it should be emphasized that such a behavior is unpredictable. Certainly, it can be easily detected, as long as one tests novels of known authorship; it becomes an obstacle, however, when one tries to scrutinize an anonymous text.

Detecting Outliers

The outcome of the above experiment shows that the minimal sample size can be lowered substantially, from ca. 5,000 running words as suggested previously (Eder, 2015), to less than 2,000 words. However, this is true only for those texts that exhibit a clear authorial signal; otherwise the risk of severe misclassification appears. To take advantage of the above results, then, one has to be sure which category an analyzed text belongs to. In a controlled experiment, the task is simple, in a real-case attribution study, however, one has no chance to fine-tune the model by testing the disputed sample against the corpus. What if an anonymous text does not reveal a clear accuracy curve, as the one in Figure 1?

To overcome the sample size issue of unknown texts, an additional measure can be involved to supplement the accuracy scores. (Due to limited space in this abstract, a compact outline of the proposed solution will be presented, rather than a complete algorithm). In the case of misclassification, one would like to know if the wrong response is consistent, or if different classes were assigned chaotically. To address this question, an indicator of consistency would be useful. The Simpson index is a very simple measure of concentration when observations are classified into a certain number of types (Simpson, 1949):

λ = Σpi2

where pi is the proportion of observations belonging to the ith type. The index can be easily adopted to indicate imbalance between assigned classes in supervised classification. To this end, the obtained classification scores (for a given sample size) have to be divided by the total number of trials (in this case, 100). The value 1 reflects purely consistent results, lower values mean that the assigned classes were fuzzy.

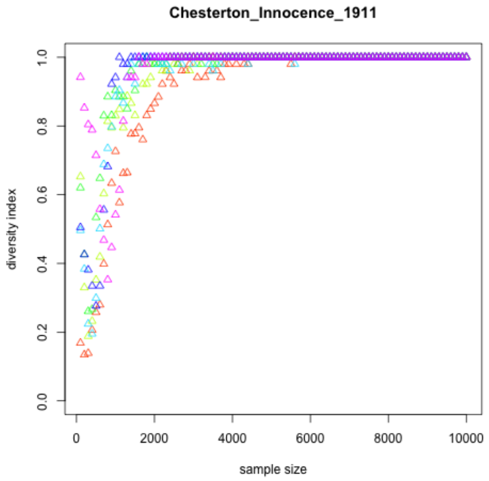

Figure 6: Diversity scores (Simpson index) as a function of sample size.

To make a long story short: the texts that distribute their accuracy curves as in Figure 1 will also exhibit the same shape of the diversity index (see Figure 6). However, when the accuracy scores are low and/or ambiguous, the diversity index might provide a priceless hint. It is especially important when the accuracy scores are consistent (Figure 5), and the Simpson index is not (Figure 7). Instead of being mislead ("Stevenson did not write Catriona", which is not true), we are warned that the classification is inconsistent. Thus, to reliably test a minimal size of a disputed text, one has to take into account two values (accuracy and diversity). The bigger the dispersion between the indices, the smaller the probability that the text is attributable – perhaps a longer sample has to be involved, or a different set of features?

Conclusion

The study was aimed at re-considering the minimum sample size for reliable authorship attribution. The results of the experiments suggest that a sufficient amount of textual data may be as little as 2,000 words in many cases. However, sometimes the authorial fingerprint is so vague, that one needs to use substantially longer samples to make the attribution feasible. A question of some importance is to which category an unknown (disputed) text belongs.

De la chaîne éditoriale à la plateforme de recherche : structurer, enrichir et diffuser de vastes collections numérisées de publications scientifiques

Nathalie Fargier
nathalie.fargier@persee.fr
ENS de Lyon, France

Brief Summary

Persée développe une plateforme de numérisation, d'enrichissement, de diffusion et d'archivage de publications francophones en SHS, de la 1ère parution à la période la plus récente (revues scientifiques, actes, livres). Résultat d'un travail collégial entre chercheurs, éditeurs, bibliothécaires et ingénieurs, cette plateforme diffuse près de 650 000 documents scientifiques en open access. Elle constitue une expérience originale et concrète pour explorer les enjeux croisés de la numérisation patrimoniale, de l'édition électronique et de l'analyse sémantique. La communication vise à décrire le passage de documents imprimés (représentation arborescente) à une publication numérique puis à un ensemble de données structurées (représentation réticulaire sous forme de graphe) et, à analyser la recontextualisation opérée et les transformations à l'œuvre. La bibliothèque numérique, l'entrepôt OAI et le triplestore Persée sont des points d'accès complémentaires et offrent des potentialités radicalement nouvelles de fouille de texte et de données, d'analyse, de mise en relation et de réutilisation.

Full abstract

Persée est une plateforme de production, d'enrichissement, de diffusion et d'archivage de collections de publications francophones en sciences humaines et sociales, de la 1ère parution à la période la plus récente (revues scientifiques en 1er lieu mais aussi actes de colloques et livres). Résultat d'un travail collégial entre chercheurs, éditeurs, bibliothécaires et ingénieurs, cette plateforme diffuse actuellement plus de 650 000 documents scientifiques en texte intégral et en *open access* et, elle poursuit son enrichissement.

Une décennie après l'ouverture de persee.fr, alors que la numérisation du patrimoine documentaire est massive et que de nouveaux modes de publication ont émergé, cette plateforme constitue une expérience originale et concrète permettant d'explorer les enjeux des collections numériques dans un monde connecté et les interactions entre numérisation patrimoniale et édition électronique. Dans le cadre de cette présentation, il est proposé de décrire les conditions du passage du monde de l'imprimé à celui du numérique, de volumes papier à un ensemble de documents structurés et reliés entre eux et, d'analyser la « *recontextualisation* » qui a été ainsi opérée et les transformations structurelles qui sont à l'oeuvre.

Méthode de fragmentation et chaîne opérationnelle de traitement

Confrontés à des objets qui disposent d'une matérialité évidente (la revue comme un ensemble de documents papier) et d'une pertinence intellectuelle (la revue en tant qu'objet éditorial), nous avons assuré une modélisation des données pour mettre en évidence les structures des documents et leurs dépendances. Ces structures sont représentées dans un modèle qui contrôle la validité des documents. La chaîne éditoriale Persée réunit un ensemble de méthodes et d'outils permettant de constituer des corpus numériques en XML, de manière intégrée et largement automatisée, en vue de leur indexation fine, leur diffusion et leur archivage. Les métadonnées sont encodées selon les schémas Dublin Core, MarcXML et MODS. Le texte intégral issu de la ROC (**reconnaissance optique de caractères**) est disponible selon le schéma TEI et enfin, l'ensemble des données est décrit et organisé au sein d'un container XML au format METS. La publication des documents s'opère par des algorithmes de transformation qui s'appuient sur le modèle pour publier des documents dans des formats standards.

De l’arborescence au réseau : l’évolution de la représentation logique des documents

Les publications scientifiques imprimées sont organisées selon une logique arborescente avec, pour les revues, par exemple, un agencement de type : titre/année/tome/volume/numéro/article. Cette représentation abstraite fait l’objet d’une retranscription numérique jusqu’à un niveau plus précis qui est celui du plan des articles, de la liste des illustrations, des résumés et, des annexes, etc. Considéré isolément et intrinsèquement, l’article devient le nœud d’un nouveau maillage en se fondant sur l’exploitation des citations, des noms d’auteurs et des informations en son sein même. Nous mettons en œuvre un référencement croisé (cite / cited by) et un alignement sur des référentiels d’autorités Auteurs et des sources comme DBpedia. Une analyse plus fine des articles permet d’identifier des entités nommées et d’établir des liens avec des thesaurus disciplinaires. Loin de tout traitement massif, la méthodologie retenue combine des algorithmes de recherche ciblée soumis à validation humaine afin de garantir pertinence et qualité. Les objets numériques ainsi créés se distinguent fondamentalement du matériau papier de base et ils offrent des potentialités majeures en termes de recherche, de Text and Data Mining, d’analyse et de mise en relation. Ainsi, le numérique permet-il de référencer parallèlement la collection appréhendée comme un objet intellectuel à part entière, des segments constitutifs (article/communication/chapitre) et des données, de multiplier les points d’accès à un ensemble structuré, contextualisé et historicisé.

Ouverture de l’accès, ouverture du code source et ouverture des données

Dès l’origine, la voie de l’*Open Access* a été retenue pour la diffusion sans aucune restriction des métadonnées et des documents en texte intégral, l’ouverture et le partage étant considérés comme des instruments essentiels de visibilité et de circulation de la production scientifique dans un environnement où la langue française n’est plus en situation d’hégémonie. Selon une suite logique, les développements informatiques ont été opérés dans un esprit *Open Source* et les données Persée sont intégrées au web de données sous la forme de triplet RDF. L’objectif poursuivi est double : favoriser la réutilisation des contenus dans d’autres contextes que ceux qui ont vu leur création et l’accès de tous au patrimoine scientifique au-delà des cercles académiques.

Introduction

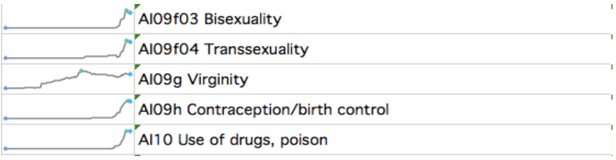
The Linguistic DNA project (LDNA) is an AHRC-funded collaborative project (AHRC grant AH/M00614X/1) between the universities of Sheffield, Glasgow, and Sussex which is designing automatic processes to investigate the emergence and development of concepts in pre-1800 CE print. Employing Early English Books Online, manually-transcribed through the Text Creation Partnership (EEBO-TCP) as its primary dataset, supplemented by Eighteenth Century Collections Online (ECCO-TCP) and other high-quality 18th-century text collections, the project is developing and refining a processing pipeline which assembles groupings of words bound together by their contextual use in printed discourse. The project is charting development of these discourse-embedded word groups across time, investigating how they are shaped by historical and literary contexts, the boundaries and overlap between the groupings, and the interaction of 'encyclopedic' groupings with more traditional 'thesaurus'-style semantic fields.

This paper discusses results from a branch of the project which is investigating incidences of rapid change in the size of semantic categories as represented in *The Historical Thesaurus of English* (Kay et al., 2016). Development of concepts through size of *Thesaurus* categories has been investigated previously (cf. Alexander and Struan, 2013; Jürgen-Diller, 2014), although the extra dimension provided by the outputs of the LDNA processor allows a dramatic leap forward in such research by enabling identification of instances in which change in discourse-embedded word groupings acts as catalyst for corresponding rapid change in the semantic fields of English.

The present case study investigates words relating to the concept of 'virginity', utilising processed time-slice subsets of EEBO-TCP as snapshots of the discourse context for these words in Early Modern English print. By building sample word-groupings (the term 'cluster' is here avoided to avoid confusion with cluster or network analysis word clusters) for each of the subsets, it establishes the discourse context of 'virginity' words at different points in the timespan covered by EEBO-TCP. Comparison of these groupings suggests change in focus of language users, through which a largely religious context of use opens out to a secular and then a poetic literary context, suggesting that society's consciousness of this concept and the scale on which it was discussed enlarged dramatically in the period covered by the sub-corpora.

Methodology

In order to select a *Historical Thesaurus* category for analysis, an average pattern of change over time was established. The *Thesaurus* arranges the words of the English language into a semantic hierarchy that is seven category levels deep with the potential for up to four further sub-category levels within any given category. Owing to the incredibly fine-grained nature of the sense categorisation in the *Thesaurus*, it was necessary to 'cut' the hierarchy at human scale using a thematic category set, developed during the AHRC- and ESRC-funded SAMUELS project (Grant AH/L010062/1), which is intended to allow *Thesaurus* users to find information at a level that is salient to human beings – i.e. neither too general nor too detailed.



AI09f03 Bisexuality
AI09f04 Transsexuality
AI09g Virginity
AI09h Contraception/birth control
AI10 Use of drugs, poison

Figure 1: Sparkline showing growth of 'Virginity' category from 1000 CE to 2000 CE in context of surrounding thematic categories (which are themselves unusual as they are lexicalised only in later periods of English)

The number of lexemes within each category level was counted, and lexemes were filtered to include only those active within the approximate time range of the EEBO-TCP collection, i.e. 1475-1700 CE. This data was aggregated so that the change in the mean contents of a category could be viewed across time, and decade-to-decade percentage changes calculated. Individual categories were then compared to this average category change, and a deviation of more than 5% from the average change considered to be significant. Out of the categories which were marked as statistically unusual from this process, category 'AI09g Virginity' was selected as promising because the items in its lexis had a relatively low number of homographs that could skew the results towards irrelevant information.

Testing of the LDNA processor outputs is being conducted on select subsets extracted to provide snapshots across the EEBO time-period. The subsets used for this paper cover the periods 1520-39, 1550-59, 1610-11, and 1649. They are designed to contain a similar number of tokens; the progressively contracting timespans reflect the concomitant growth of printed material throughout the 15th to 17th centuries. Each token in the text is regularised, lemmatised, and tagged with a NUPOS part of speech tag via the MorphAdorner pipeline developed by Martin Müller and Philip Burns (Burns, 2013). Data is then gathered by the LDNA processor for the token's co-occurrences within 100- and 200-word bi-directional windows which are intended to simulate paragraph-like sections of the proximate discourse (cf. Fitzmaurice *et al.* forthcoming). Pointwise Mutual Information (PMI) is used to provide a statistic for likelihood of word co-occurrences; a minimum PMI value of 0.5 was arrived at experimentally for identifying node-collocate pairs to be considered interesting in initial stages of investigation.

Seven items – 'maid,' 'maiden,' 'maidenhead,' 'undefiled,' 'vestal,' 'virgin,' and 'virginity' – in the 'Virginity' category were found to be present consistently across the subsets (although an eighth – 'virginal' – was present in the 1520-

39 and 1610-11 subsets). The co-occurrences were then processed to identify those which occurred with multiple items in this list. Words which co-occurred with four or more items were investigated further.

Results

Comparison of the co-occurrence results across the five text subsets shows a consistent shift in the patterns of word association with 'Virginity' category items. The words 'woman' and 'widow' remain strongly associated with the terms across all the subsets, demonstrating societal preoccupation with female rather than male virginity. The most evident change in the grouping is movement from a predominately religious discourse context into the secular world. In the 1520-39 subset, the Virgin Mary is intimately related to discussion of virginity. In the shared collocates listing, *mother* collocates with all seven of the 'Virginity' lexemes, 'mary' with six, 'angel,' 'bless,' 'hymn,' 'nativity,' and 'nazareth' with five each. Of these, only 'mother' maintains a strong association with 'Virginity' words throughout the EEBO period, appearing with four items in the 1610-11 text set and five in 1649.

The secularisation of the term is suggested by the prevalence in later subsets of words relating to marriage, reflecting what appears to be a growing focus on wedlock being preceded by virginity. 'Marry' gradually increases its association with the node items, collocating with four, then five, then seven from 1520 to 1649. 'Marriage' and 'wife' both enter the shared collocate group in 1550, and remain there through to 1649, whilst 'matrimony' is present in 1550, drops out in 1610, and returns in 1649.

The extensive list of shared collocates in the 1649 subcorpus strongly reflects the greater prevalence of literary fiction and poetry in printers' output and reinforces that virginity is a topic for which the discourse context is expanding; where it was easy to intuitively group 'marry,' 'marriage,' and 'wife' together, the 1649 collocates do not form easily identifiable groupings.

Discussion

The consistency of the core items found in the subsets is interesting in its disparity with the *Thesaurus* data, where the increase in the number of terms present in the 'Virginity' category suggests that there should be an expanding number of items found throughout these subsets. The most likely explanation for this is loss of low frequency information through a combination of cut-off values intended to reduce noise for later clustering experiments, and difficulty in normalising/lemmatising low frequency items. A clear outcome of the analysis is the confirmation that the category of 'Virginity' contains core vocabulary which remains almost unchanged in over a century (i.e. 1520-1649), primarily a consistent group of seven items which co-occur with 'Virginity' category words.

This study demonstrates that understanding of semantic development can be enriched by such cross-analysis of discursive-concept word groups with *Thesaurus* semantic fields and the word groups which travel through time with multiple items of *Thesaurus* categories.

Introduction

Cet article présente les résultats d'une recherche dans le cadre de laquelle nous nous sommes intéressés à l'évolution thématique de l'art contemporain dans les centres d'artistes autogérés du Québec. Nous dressons un portrait du milieu de l'art et de son discours en analysant automatiquement un ensemble de textes d'expositions. Notre approche repose sur des techniques automatisées de fouilles de textes. Notre objectif est donc de cartographier l'évolution des thématiques abordées dans le discours en art contemporain.

Notre approche s'inspire de la notion de *distant reading* développée par Franco Moretti. Selon Moretti, l'analyse des textes devrait être effectuée non pas sur une sélection d'ouvrages (le "canon"), mais sur l'ensemble le plus exhaustif possible de documents. Un échantillon de documents trop limité ou trop spécifique risque d'engendrer une perte d'informations précieuses.

Dans le domaine des arts, K. Bender s'est inspiré des travaux de Moretti afin de développer la théorie du *distant viewing.* Appliqué en histoire de l'art où les monographies se concentrent souvent sur les grands artistes et aux grandes oeuvres, il importe de développer, selon Bender, un "regard" permettant de saisir et d'analyser un très grand ensemble d'oeuvres d'artistes. Bien qu'il existe des techniques informatiques permettant d'analyser des images et en extraire des mots-clés descriptifs, ces techniques ne font qu'une description visuelle de l'image.

L'image ou l'oeuvre d'art, qu'elle soit figurative ou abstraite, ne se décode pas simplement. L'art visuel nécessite une analyse qui ne se limite pas au niveau descriptif. Interpréter une oeuvre d'art nécessite à priori certaines connaissances, notamment sur le travail et la démarche de l'artiste, le contexte socio-historique de l'oeuvre ou sur l'histoire et la théorie de l'art. Dans ce contexte, le texte d'exposition constitue un médium riche à exploiter pour extraire de l'information sur les oeuvres.

Le texte d'exposition

Les textes d'exposition en art ont comme objectif de situer et de contextualiser les oeuvres. Ils permettent une meilleure compréhension des oeuvres, du processus créatif de l'artiste, des thèmes, ainsi que des questionnements et des idées évoqués dans les expositions. Dans ce contexte, l'utilisation de techniques de fouille de textes, et plus spécifiquement de modélisation thématique (*Topic Modelling*) (Blei et Lafferty, 2009), permet d'extraire automatiquement les thématiques à partir de textes d'exposition qui n'auraient pu être extraites automatiquement à partir du contenu visuel et qui, à grande échelle, seraient beaucoup difficiles à identifier manuellement. En analysant tous les textes d'expositions disponibles pour une période donnée, nous pouvons poser un regard différent sur le discours en art. L'application de la modélisation thématique sur des textes d'exposition permet, en effet, d'extraire et de structurer automatiquement les principaux thèmes d'un corpus et d'en décrire le vocabulaire spécifique, en plus de permettre la classification d'oeuvres thématiquement comparables. (indépendamment de leur qualités visuelles).

Modélisation thématique et *Artspeak*

Le langage propre au milieu de l'art contemporain, parfois appelé le *Artspeak* ou *International Art English* (Levine et Rule, 2013), peut être difficile à décoder pour les non-initiés. Il a cependant comme qualité de permettre l'expression d'idées et de concepts abstraits propres à l'art contemporain, afin de lexicaliser la complexité des oeuvres. Comme le mentionne Levine, "IAE is about trying to create a more sensitive language, acknowledging the realities of how things [made by artists] work."

La modélisation thématique la complexité des textes ou au niveau d'abstraction des phrases. Il permet, par simple calcul de distribution des mots, de regrouper des textes portant sur des thématiques communes. La modélisation thématique est fréquemment réalisée par l'algorithme LDA (*Latent Direchlet Allocation*), développé David M. Blei, Andrew Ng et Michael I. Jordan en 2003. Bien qu'il ait été développé, il y a plusieurs années, cette algorithme fait l'objet d'un nombre croissant d'utilisation dans le traitement des textes en humanités numériques (Graham, Milligan et Weingart, 2016). Le principe qui sous-tend cet algorithme est qu'un corpus de textes est composé de nombreux thèmes ("topics") latents; ces thèmes étant exprimés par les différents mots qui le composent. Les thèmes sont donc des regroupements de mots effectués sur la base d'un calcul de probabilité (bayésienne). Au niveau individuel, un document est composé d'un nombre *k* de thèmes, lesquelssont composés d'un nombre *x* de mots représentés selon différentes proportions. Au niveau macro (au niveau du corpus en entier), tous les documents d'une collection partagent les mêmes thèmes. L'algorithme LDA présuppose donc l'existence des thèmes latents qui n'apparaissent pas explicitement dans les documents. Ce principe évoque ainsi l'idée d'une structure cachée du document qui nous permet de dégager une structure de mots sur la base de leur proximité thématique. Les mots du corpus sont tous regroupés dans différents thèmes, tout en ayant la possibilité de se retrouver dans plus d'un thème à la fois.

Expérimentation

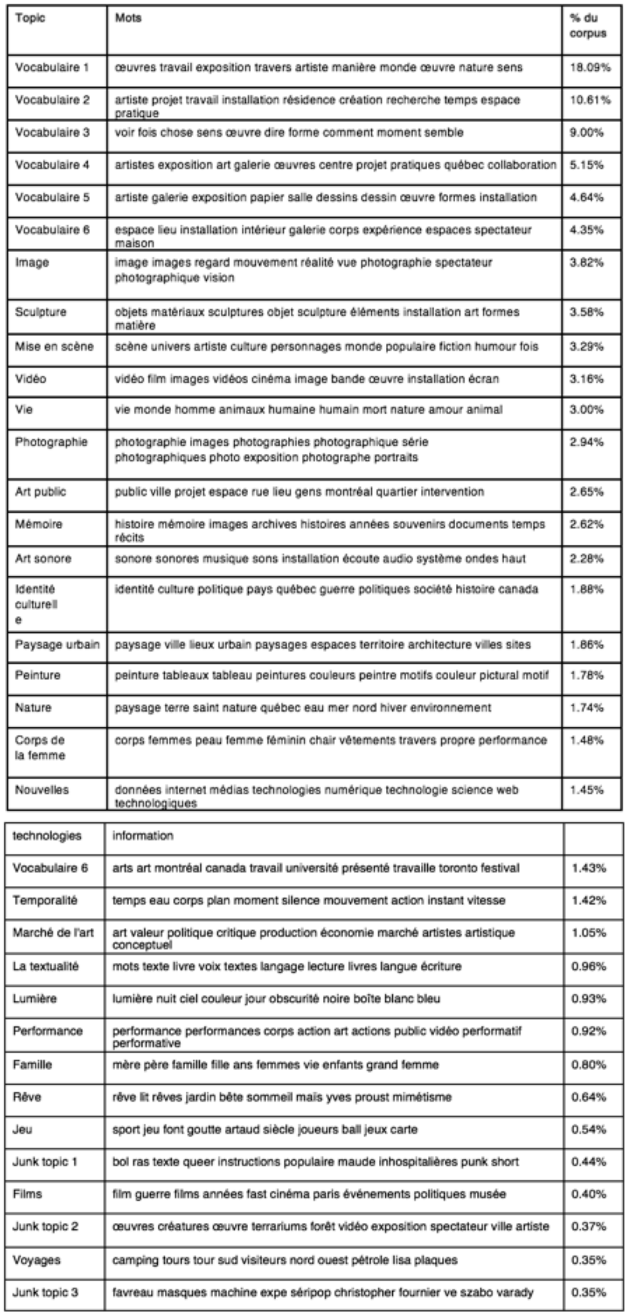
À partir d'une liste exhaustive de galeries d'art membres du RCAAQ (Regroupement des centres d'artistes autogérés du Québec), nous avons constitué un corpus composé de tous les textes d'expositions disponibles sur les sites Web des centres d'artistes (nous définissons ici "exposition" de manière peu restrictive. Il peut donc s'agir de performances, d'événements hors site ou d'expositions individuelles ou collectives). Un total de 3 867 textes d'expositions ont ainsi été trouvés en ligne, datant de 1973 à 2016 et provenant de 49 centres d'artistes autogérés différents. Les données ont été soumis à un processus de modélisation thématique dans l'application *Mallet*.

Divers prétraitements ont été appliqués au corpus initial afin de n'en retenir que le vocabulaire spécialisé en art (suppression des mots fonctionnels, filtrage par seuils statistiques, etc.). Par la suite, le corpus a été soumis à l'algorithme LDA de manière itérative, tout en modifiant le nombre de thèmes afin d'observer les différences dans les thèmes extraits. Le défi intrinsèque à cette approche réside dans le choix du nombre optimal de thèmes à extraire à extraire. Ce paramètre doit être déterminé manuellement.

Nous avons donc analysé un par un les thèmes automatiquement extraits et jugé de leur cohérence, en retournant et en remettant en contexte les termes extraits à l'intérieur des textes originaux. Nous avons finalement opté pour un total de 35 thèmes, nous permettant ainsi d'obtenir un maximum de thèmes cohérents et un minimum de thèmes peu significatifs. Les thèmes ont été étiquetés manuellement à partir des mots les plus représentatifs de chaque regroupement.

Résultats

Le tableau 1 et la figure 1 présente les résultats générés par l'algorithme de modélisation thématique.



Topic	Mots	% du corpus

Tableau 1. Résultats de la modélisation thématique.

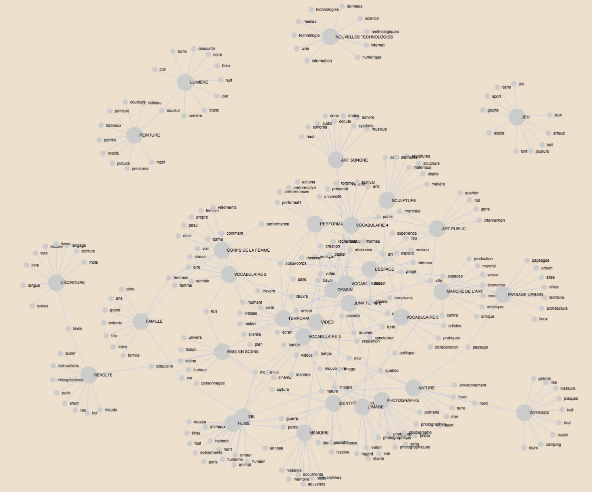

Figure 1. Résultats structurée de la modélisation thématique.

Une analyse des résultats obtenus met en lumière que la notion de thèmes se manifeste de différentes manière dans notre corpus. Ainsi, certains thèmes sont composés de mots-clés spécialisés et très caractéristiques des textes d'expositions (installation résidence création recherche temps espace, par exemple). Par ailleurs, d'autres regroupements thématiques renvoient sans équivoque à une discipline ou à une technique artistique (vidéo film images vidéos cinéma image bande œuvre). Les résultats du modèle thématique obtenu à partir de notre corpus de textes en art contemporain peuvent être synthétisés de la manière suivante :

1. les mots (les thèmes étiquetés « vocabulaire ») couramment utilisés (comme les verbes voir, faire, sentir) dans les textes d'exposition ou dans le discours artistique
2. les thèmes en art contemporain (révolte, famille, mémoire, rêve)
3. les disciplines ou techniques en art (peinture, sculpture, vidéo, photographie)
4. les thèmes incohérents (« junk topics ») (c'est-à-dire les regroupements sans cohérence apparente).

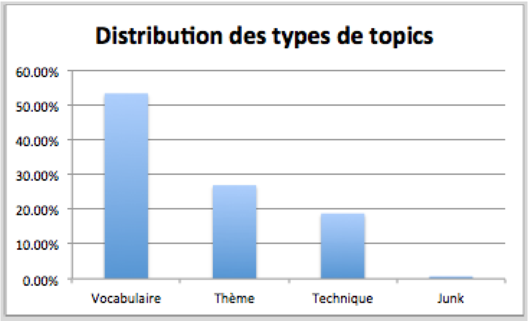

Figure 2. Distribution des types de thèmes.

Nous constatons la prépondérance des thèmes traitant du vocabulaire en art contemporain par rapport aux regroupements par sujets ou par technique (figure 2). En effet, la majorité des documents de notre corpus partagent un vocabulaire de base commun, un lexique propre aux textes d’exposition, constituant en quelque sorte le jargon du milieu. En excluant les mots vides, les textes d’exposition semblent donc composés surtout de mots sur le travail général de l’artiste en art (artiste, exposition, travail, projet, création, etc.). Le reste du corpus est consacré aux thématiques et à la technique.

Nous avons cherché à analyser les résultats du modèle thématique en diachronie afin d’observer l’évolution des thèmes dans le temps. À cette fin, nous n’avons conservé que les documents ayant été publié depuis les 16 dernières années, puisque nous ne disposions de très peu de documents dont la publication était antérieure à l’an 2 000. Nous présentons ici que certains thèmes pour lesquels une variation chronologique significative a été notée. Ainsi, les thématiques (figure 3) du “marché de l’art” et la “nature” ont fait l’objet d’un traitement croissant, alors qu’il en va inversement pour les thèmes du “rêve”, de la “famille”, de la “temporalité” et du “corps de la femme”.

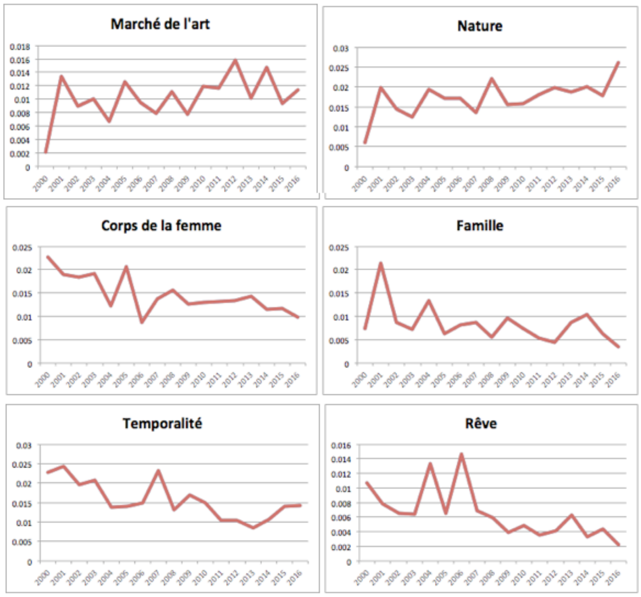

Figure 3. Thèmes à variation chronologique significative.

Les discours sur les techniques telles que la sculpture, l’art sonore ou les technologies numériques sont à la hausse depuis 2 000. Nous constatons que le discours sur la peinture est relativement stable, alors que celui sur la photographie et l’art public sont en baisse après avoir connu un intérêt marqué au début du 21e siècle (figure 4).

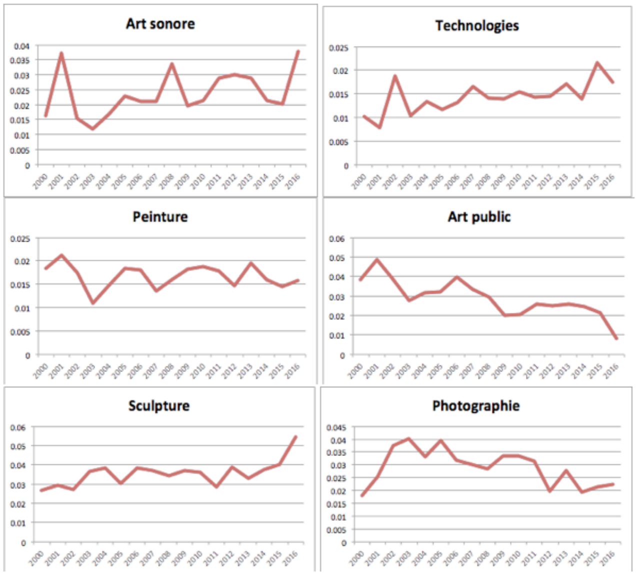

Figure 4. Les techniques à variation chronologique significative.

Conclusion

Dans le cadre de ce projet, nous avons appliqué la modélisation thématique sur un corpus de textes d’expositions en art contemporain dans les centres d’artistes autogérés du Québec. Les résultats témoignent de l’hétérogénéité des thématiques abordées. Ainsi, certaines thématiques concernent des techniques particulières, alors que d’autres reflètent le vocabulaire spécialisé en art contemporain. Une analyse diachronique des résultats nous a permis de constater l’évolution des thématiques abordées dans les textes produits par les centres d’artistes autogérés du Québec. Cette approche basée sur la notion de “distant reading”, appliqué en histoire de l’art, nous a permis d’observer d’un point de vue macro à la fois les tendances d’un milieu artistique et le vocabulaire communément utilisé dans les textes d’exposition.

Introduction

The Digital Humanities Lab (DHLab) is a research group within the faculty of Humanities of the University of Basel. The research profile of the DHLab integrates computer science, digital imaging, computational photography and the accessibility of digital objects in humanities research. The project “Digital Materiality”, an interdisciplinary project in collaboration with the Seminar of Art History, examines how new digital methods and techniques can be used to describe the reflection of light on surfaces of artworks. Of main interest are mosaics and early prints; both categories have a strong interaction with light and standard photographic approaches are not able to capture the dynamic component of the light-surface interdependence that is specific for this kind of objects.

For art historians who study and work with mosaics or any other object of complex surface composition, it is difficult to capture and visualize the important surface features in such a way that research can be done with the reproduction. The major problem is the static nature of photographic reproductions, which does not allow interaction. Static, two-dimensional photographs cannot visualize appropriately the sparkling effect caused by the surface properties of the countless light reflecting tesserae of a mosaic, for example. Similar considerations apply for early prints, books and parchments. The visual impression that these objects convey is hardly delivered by a photograph. Metallic inclusions give the artwork a dynamic appearance caused by the change of reflectance behavior of glossy compared to matte material. Furthermore, the scholar may want to integrate information coming from other types of scientific photographs, such as infrared or ultraviolet illuminated or induced fluorescence images, to increase the visual impression of renderings of artwork. In particular, the combination of such scientific photographs with other imaging techniques like Reflectance Transformation Imaging is advantageous because multiple visual impressions can be combined in a way that would not be possible in reality.

Reflection Transformation Imaging

RTI (Reflectance Transformation Imaging) (Mudge et al, 2007; Malzbender et al, 2001) is a promising approach to go beyond the limitations of conventional photographic methods. However, RTI, as it is used today, has some drawbacks that are critical in the context of the reproduction of mosaics, metallic inclusions or most other artwork.

RTI makes it possible to interactively display the light reflection as a function of the light incident angle and the structure of the surface captured. RTI needs a series of digital images from a fixed camera position, in which the light source is illuminating the object in each capture from a different position. In order to produce RTI renderings of objects of different size, several lighting systems have been developed that consist of a number of light sources that are mounted on the inside of a hemispherical dome. Those light sources can be switched on and synchronized sequentially with a digital camera. The fixed design ensures a fixed and equal distance between the numerous light sources and the object. Thus, with such an automated setup the image capture process is drastically accelerated and, in addition, ensures a high reproducibility. In the Digital Humanities Lab such a dome has been developed as well; In this specific case it is an alloy design, which is equipped with 50 LEDs and an electronic control system, which enables the automatic sequential triggering of the light sources and the synchronization with the camera. The image sequence, recorded in this way, serves in a second step as data basis for a subsequent pixel-based modeling. For this purpose, a mathematical model - normally a function of second order - is fitted for each pixel position, which represents the set of all image points from the different directions of illumination, i.e., it is parameterized so that the square mean error of all data points relative to the function curve becomes minimal.

The reflection model so far used in the original RTI method described by Hewlett Packard (Mudge et al, 2006) corresponds to the mentioned simple second-order function. Thus it has only a relatively low mathematical complexity and therefore a limited precision to represent the actual surface reflection. This specific function, however, describes matt surfaces, a Lambertian radiator, very precisely. However, this method is not suitable for glossy materials, since this simple model does not correspond to the physical laws of gloss reflection. A further disadvantage is that the method, as it is usually used today, needs a specially designed viewer application.

In the Digital Humanities Lab, the method has been enhanced in order to be able to present more complex surfaces that are made from different materials. In our approach the complexity of the mathematical model is increased so that we can handle diffuse and gloss surface components at the same RTI image. In other words, this improvement makes it possible to model and display materials with different gloss levels using the same mathematical model.

A suite for humanities scholars ‘needs

For humanities research another important aspect is the compatibility to web-based Virtual Research Environments (VRE). In principle, a functional graphical "front-end" with a connection to a database can be called a VRE. The aim of such a digital infrastructure for research is to allow scholars to work with methods and tools in the digital domain as they would do it in a conventional “analogue” process. This should be done in such a form that the scientists can intuitively recognize and use the well-known concepts and working methods that are offered by the VRE. This requires some basic functions:

- In any case, a browser-based client-server solution is preferable to a stand-alone application. In such a way collaborative work can be more easily achieved.
- In many humanities disciplines intensive work is being done with image material and objects, in which specific areas (region of interest, RoI) are often to be emphasized. Therefore corresponding graphic elements (lines, polygons) are necessary, with which such areas can be marked. These graphical elements can, for example, be polygonal line sections or rectangles, which allow the marking of object parts.
- The method of evaluating image material, which is common in the human sciences, is of a more qualitative nature. This kind of work requires extensive and powerful tools to capture descriptive and contextual metadata (annotations, transcriptions, comments). These meta-objects have to be linked with the actual primary object and need also to be stored in this way.

The visualization in a VRE must be multi-media. Besides text, image, sound and video, it is also of advantage to be able to display objects in a virtual 3D space.

To be able to integrate an RTI solutions into a web-environment to support real-time collaborative work needs specific web-technologies (Palma et al, 2010; MacDonald and Robson, 2010). The presented RTI viewer is fully web-compatible and it can be integrated in most browsers to support high-quality client-side visualization; the key technology that allows this integration is WebGL. This OpenGL-based programming interface, which has been optimized for "embedded systems", is nowadays integrated into any modern Web browsers. WebGL is a license-free standard developed to work seamless in conjunction with the programming language JavaScript. For the application in a browser this means that 3D functionalities are provided without the need to load any additional plug-ins. The performance and range of functions of WebGL are impressive. WebGL is also supported on most mobile devices, such as smartphones and tablets, which further increases the range of applications. The improved performance of WebGL, in contrast to many other graphics libraries, also allows for fluid interactive work. Long rendering times are left out and the visual latency is minimal. WebGL offers a variety of functionalities, ranging from simple grid models to complex animated, textured and illuminated surfaces. The fact that the use of graphic elements for marking RoIs is easily possible with this large range of functions is, of course, self-evident.

Around the left eye of the sacred head is a branding to be recognized, as well as a corresponding commentary, left in the picture window. The parameters of the viewing situation are shown on the right side, which are also stored in the data model. (Source: DHLab, University of Basel)

The integration of all those technologies and new developments allows us to present an improved solution to reproduce and render surfaces of different materials (matt and glossy) in a fully web-based environment implemented in JavaScript and WebGL, running on standard computers and mobile devices. In addition to RTI image processing, photographs in the UV and IR domain can be captured, displayed and superimposed with the same system to allow the user to compare the same region under different light condition. For flexibility, performance and data permanence aspects our RTI image server will follow the International Image Interoperability Framework (IIIF). IIIF defines a standardized URL syntax to serve digital images online in the field of cultural heritage and research. The region of interest, resolution, rotation and the file format of a requested image can be indicated on the URL. SIPI, the Simple Image Presentation Interface, developed by DHLab, provides an IIIF compliant image server which is ideally suited for our scope. Due to the fact, that the front-end is compatible with any standard web-browser, it can be integrated in a virtual research environment using Knora. Knora is a software framework, developed by DHLab, for storing, sharing, and working with primary sources and data in the humanities. Knora builds the fundament for the Swiss National Data Center for Research Data in Humanities that is operated by the DHLab. The source code is publicly available on Github at the address in reference.

This integrated environment allows researchers to interactively control the viewing and light conditions of e g. a digital mosaic rendering. Regions of interest can be chosen, annotated, saved, and shared with other scholars. The full set of contextual and technical metadata is stored and time stamped to be fully reloadable and citable back to any point of its history of changes.

Conclusions

The combination of the Enhanced-RTI and the Scientific Image Viewer (SIV) enables us to convey the impressions of these highly dynamic light-surface interactions and the information provided by IR and UV imaging e.g. to researchers who cannot visit the actual artwork in situ. The visual impression can be enriched by meta information that can shared with other scholars. The presented RTI based solution is also helpful to document the current condition of objects more accurately, e.g. before and after a restoration. Sustainability and simplicity of RTI image data is drastically improved by the use of a IIIF server. The presented infrastructure allows the strict separation of image data and meta information. As a result, any RTI image rendering is fully reproducible and therefore perfectly suited for digital archiving, following the requirements of performance, permanence and reliability.

PERiSCOPE: Personalized Color Profiles
A modern methodology for rendering colour in digital media displays

Colour and colour perception are of great relevance for many scientific fields and constitute important aspects of the aesthetic appearance of most artwork. In art history, visual arts, media sciences and photography, colour is an important attribute for assessing and reviewing most objects. Virtual Research Environments, for example, allow scholars to access, compare, and discuss digital renderings of paintings, photographs, video and motion pictures. The quality of colour rendering of these digital objects is crucial for most analytical work because colour is one of the most important features that is communicated. We propose to revolutionize the current colour rendering methodologies on state-of-the art displays and printers, for better “true” colour management of digital still images, video, or motion pictures.

Since the early years of colour science, the 1931 CIE Standard Observer has been a major reference for colour reproduction (Guild, 1925, 1932; Wright, 1929). The CIE Standard Observer defines how we can quantify colours that we see in the linear XYZ, or the perception-based Lab colour space. There are, however, several disadvantages to the system, arising mainly from the inherent assumptions made during the (very controlled) colour matching experiments used to derive the colour-matching functions (MacDonald, 2015). Most significantly, the original approach describes only the average of the experimental results, while those results are based on a small group of test individuals, in this case, 49 British men. Since the original experiment does not address the physiology of an individual observer, it has several qualitative limitations that result in colour reproduction with limited accuracy.

Since the original Standard Observer experiment, several studies have been performed aiming to improve the original colour matching functions (CMFs). Stiles and Burch, in 1959, repeated the experiment this time with an increased viewing field of 10 degrees, from the 2 degrees used for the 1931 results (Stiles & Burch, 1959). More recently, in the ‘90s, groups critically analyzed the 1939 and 1959 results to derive more precise CMFs. This is the case with Stockman et al in 1999 (Stockman, Sharpe, & Fach, 1999), who were able to propose new spectral sensitivity functions for the S-cones (the eye’s short-wavelength light receptor), both with their own experimental methods and by analyzing the existing functions. Meanwhile, individual differences in CMFs were estimated by North and Fairchild in 1993, this time by performing a small number of colour matching measurements and using a computational model to derive the CMFs (North & Fairchild, 1993a, 1993b). Investigations of individual variabilities in detecting colour among colour-normal individuals were performed in 2015 by Asano et al. and showed higher than expected interobserver variability (Asano, Fairchild, Blondé, & Morvan, 2015).

There are multiple studies that have been investigating the connection between colour perception and physiological (Abramov, Gordon, Feldman, & Chavarga, 2012a)(Abramov, Gordon, Feldman, & Chavarga, 2012b) and cultural (Collier, 1973; Merrifield, 1971)(Winawer et al., 2007)(Roberson, Davidoff, Davies, & Shapiro, 2006) differences, however the mechanisms that control the individual colour perception (i.e. the specific way that each person sees, understand and responds to colour) are not fully understood.

In this project, we plan to revisit the Standard Observer Experiment (SOE) and test its validity for different portions of the population. We will employ current technologies to develop and use a modern experimental setup based on LEDs and emphasize on these specific parameters of interest:

- The target colour in the full range of wavelengths in the visible range
- The geometry (size) of the colourfield
- The background the colour is surrounded by (limited to a specific set of colours)
- The ambient light conditions

The group of probands shall comprise of a large pool of individuals representing different ages, genders, social background and cultures. Our experimental setup will help to simplify the measurements of individual tristimulus functions for a more generalized application.

The original SOE has already shown a large variety of individual results, even though the number of probands was very small. Especially for the red primary, the observers have shown large differences in the required colour-mix to get a perceived colour match between the target colour and the mixing colours. With the experimental results we will confirm these differences in the colour matching experiment and move further to quantify the deviation both in wavelength and intensity of the individual tristimulus functions. If the principal shape of the three functions is comparable and the frequency shift is small relative to the full visible range, the experimental setup needed to measure the individual colour-matching functions can be drastically simplified.

Additionally, we pursue the development of a simplified experimental setup that will have a more generalized use. Previous colour-matching experiments using LEDs provide invaluable insight into the technical regarding optics requirements and electronics design (Morvan, Sarkar, Stauder, Blonde, & Kervec, 2011). The setup will consist of a device that can illuminate a test area with a red, blue and green primary of adjustable intensity. With such a mobile colour-matching device, the SOE can be simplified. The simplification of the experiment allows for observers to characterize their individual colour perception in a fast and uncomplicated way. The long-term goal is to develop automated single-observer colour measuring, which can be used to create personalized colour profiles (PERsonalIzed COlour ProfilEs PERiSCOPE), with which we will be able to uniquely calibrate the user’s viewing instruments, i.e. screens, printers etc. that are part of a conventional ICC colour management workflow. A simplified but straightforward experiment is the calculation and rendering of an image based on the scaled integral of spectral image data, regarded as spectral reflectance information for each pixel, S(λ, px, py) multiplied by the spectral power distribution of the illuminant I(λ) and e.g. the two extrema of the CIE's color matching functions $x_{min}(\lambda)$, $y_{min}(\lambda)$, $z_{min}(\lambda)$ as well as $x_{max}(\lambda)$, $y_{max}(\lambda)$, $z_{max}(\lambda)$. Such an experimental calculation results in two significantly different images, each representing a rendering based on different experimental data sets of individuals of the SOE. Such different renderings might have a significant effect on the perception of image data and it is a step towards the separation and equalisation of the various effects in the human visual system.

The results and the consequences of the project will be assessed together with experts of art history, media sciences and psychology. We believe that the implications of using personalized color profiles for image renderings will have a strong impact on various fields within the (digital) humanities, which will pave the way for new findings and better understanding. How is e.g. the same rendering of a colour photograph seen by two observers with different physiology? What are the effects of the perception of colour if the colour is adjusted to the physiology and described by of the two observers? How is an observer reacting, if the two observer renderings are shown to the same observer, showing the differences clearly? What effect has such an adjusted colour rendering to the description of eg. colour aesthetics? What is the consequence of seeing an image which is rendered for colour according to the data other person, in other words, if we see an artwork through the eyes of another person, eg. the artist itself? Those questions will be discussed in an interdisciplinary framework with other disciplines, especially art history and media sciences.

In terms of research in cultural heritage and art in humanities universities, museums, and other art institutes, our studies can change the way research is performed and will affect the results of this research, as the tools will become available to introduce the aspect of personal perception. Art is to a great extent a personal experience and institutes have to invent ways to make it objective in order to be able to discuss it in more general terms and draw conclusions about its effect in populations, cultures and times that may be foreign to the researchers today. The PERiSCOPE will adapt an artefact's colour on a digital display according to the viewer's profile. Thus it will allow scientists to truly see the same colour image at the same time and will help reduce the subjectivity of judging an artefact's appearance.

The DHLab also operates DaSCH (The National Data and Service Center for the Humanities), which includes a Virtual Research Environment in the humanities for sustainable collaborative work with digital sources. This web-based infrastructure can be ideally used for the discussion and collaborative evaluation of our colour results. It would make it possible for researchers to get a deeper understanding of each other's comments and critique in terms of colour. It would also enable viewers to see a work of art in the way the artist - in case he or she is still living - perceives it. Finally, if we are able to also categorize colour profiles to fit different population groups, the PERiSCOPE will also enable colour specialists (researchers or even industry stakeholders) to use colour in a way that would make the greatest impact to a specific part of the population.

Our research can also greatly impact research in psychology, in terms of personal perception and emotion, by providing new, more accessible methods for measuring and assessing responses to colour stimuli. Much of the knowledge we have about colour perception today comes from the field of psychology. For every colour-related project, researchers have to recreate some form of the SOE. With the PERiSCOPE mobile setup, we will be able to offer a standardised, easy-to-use system that will provide an efficient, reliable and reproducible methodology for these studies.

From Jane Austen's original *Pride and Prejudice* to a graded reader for L2 learners: a computational study of the processes of text simplification

University of Goettingen, Germany

Introduction

Authentic text and graded reader

One of the objectives of second language (L2) learning is to be able to read and understand a variety of texts, from novels to newspaper articles, written in the language of interest. These texts written with a native audience in mind are commonly referred to as authentic texts or ”real life texts, not written for pedagogic purposes” (Wallace, 1992). Authentic texts, however, can present too many obstacles for L2 learners with too low a level of knowledge. The complex language structures and advanced vocabulary of these 'real' texts can have the unwanted effect of demotivating the reader (Richard, 2001). The gap between the learner's limited L2 knowledge and the fluency of authentic texts creates an ideal space for graded readers. Graded readers are ”simplified books written at varying levels of difficulty for second language learners” (Waring, 2012). Through graded readers original classic works can be adapted to match the learner's level of knowledge, thus providing the ideal tool to tackle 'real' themes, narratives and dialogues.

From authentic text to graded reader

One such graded reader is a newly adapted version of Jane Austen's *Pride and Prejudice* (edition of 1813) that one of the authors of this paper wrote (Franzini, 2016) as part of a collection for learners of English as a foreign language (EFL).

For authors, the process of adaptation of a text for a learning audience is complex. In order to simplify the text the author will necessarily have to make grammatical changes and lexical substitutions following vocabulary lists, shorten the text by cutting out entire paragraphs and events, and in some cases eliminate entire chapters and characters. Together with these changes, which can be defined as 'structural' because they are dictated by hard requirements of length and standardised level of difficulty, the author will also make a series of judgment calls at a sentence and word level. These changes, which are here defined as 'cognitive', include processes that are more intangible and that are a consequence of a native author's 'feeling' that the original text is too difficult for learners. These include elaborating, clarifying, providing context and motivation for unfamiliar information and non-explicit connections (Beck et al., 1991).

Research Objective

The objective of this study is to computationally analyse the manual process behind the simplification of a historical authentic text aimed at producing a graded reader. More specifically, it aims to classify and understand the structural and cognitive processes of adaptation that a human author, more or less consciously, is able to perform manually. Do the applied changes follow strict rules? Can they be classified as forming a pattern? And if so, can they be reproduced computationally?

Related Research

Researchers have long been addressing the issue of text simplification for a variety of purposes. A similar study to this was made by Petersen who compared authentic newspaper articles with abridged versions (Petersen and Ostendorf, 1991). Similar studies have been made, for example, to create a reading aid for people with disabilities (Canning, 2000, Allen, 2009).

Data

This study considers two sets of data. The first is the entire original novel (ON) *Pride and Prejudice*. The second dataset the graded reader (GR) published by Liberty. The GR has been compressed from the 61 chapters of the ON to 10 chapters. When comparing word tokens, the GR has a size of 12.6% of the ON (Tab. 1). The language was simplified to match the upper intermediate level B2. To guide the choice of vocabulary, the author chose to follow the Lexitronics Syllabus (Lexitronics, 2009).

	Line count	Word tokens	Word types	Average sentence length
Original Novel	5,974	143,386	6,823	24.00
Graded Reader	1,115	18,086	1,813	16.22
% GR size in respect to ON	18.6%	12.6%	26.5%	67.5%

Table 1: Quantitative comparison between data sets

Methodology

Readability

As a first step towards analysing the differences and similarities between an authentic text and a graded reader, we decided to evaluate if what is published as a graded reader can computationally be considered a simplified version of the original. The method chosen to make this investigation was to conduct two different readability tests, namely the ARI test and the Dale-Chall Index test on the data. Both tests were designed to gauge the comprehension difficulty of a text by providing a numeric value, which corresponds to a particular school level of a native speaker of the language tested.

The results show that both tests yield similar scores and satisfy the hypothesis that this particular GR can be computationally proven to be, in terms of 'understandability', a simplification of the ON.

	ARI	Dale-Chall
Original Novel	14-15 year olds	14-16 year olds
Graded Reader	11-12 year olds	11-13 year olds

Table 2: Age level of text understandability

Difference Analysis

In order to analyse the process of adaptation, a difference analysis was conducted by considering both those elements that changed from the ON to the GR, and those that, by contrast, remained the same. The analysis is structured into chapters, sentences and words, so as to proceed in order from the largest unit of text to the smallest.

When adapting a text, whether it is for a graded reader, a play or a film, the rationale behind the selection of certain parts over others is normally content-based. Here the author selected the most dynamic parts of the novel, which included dialogues, moments of suspense, movements of the characters and revelations. The selection of some scenes of the plot over others is purely a 'cognitive' choice of the author because it is entirely subjective. However, by using a text reuse detection software (TRACER) on both texts it was possible to visualise where the majority of reuses occur. These concentrate in particular around the beginning and the end of the novel (dark green in Fig. 1).

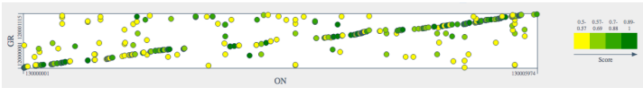

Figure 1: Dotplot visualisation of the reuses between the ON and the GR. The longer X-axis represents the larger original novel, the Y-axis the smaller GR. The darker the dot, the closer the similarities between the two datasets

'Structural' changes made at a sentence level present patterns that can be more systematically identified. For example, by comparing sentence length, it was noted that on average the ON contains longer sentences (24 words) than the GR (16.22 words) (Fig. 2). Though this might seem like an obvious result, it appears less so when one thinks that, in order to simplify a concept for a language learner, it is often necessary to use additional words to elaborate or clarify it.

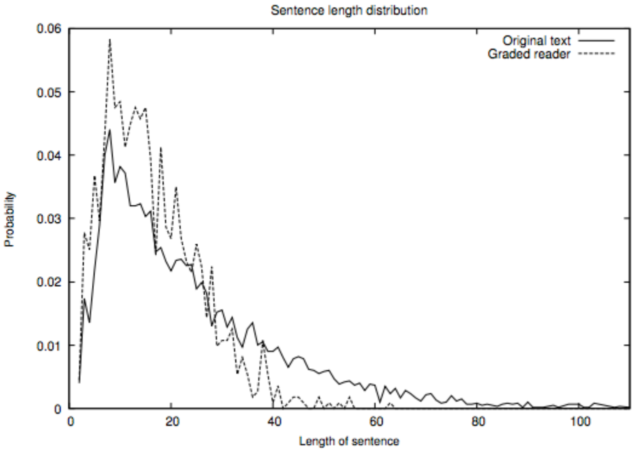

Figure 2: Sentence length distribution. The X-axis represents the number of words per sentence; the Y-axis is the probability of sentences of a specific length occurring in the texts

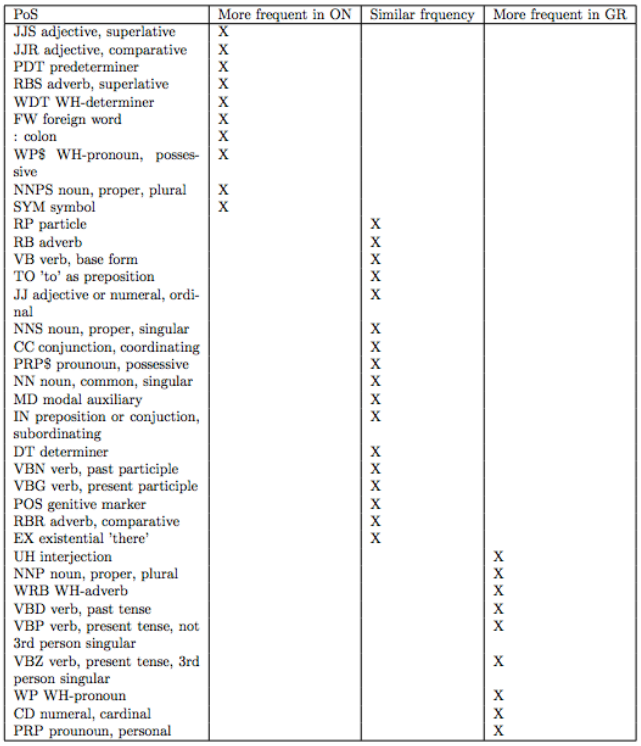
In order to conduct a difference analysis on the smallest unit of text - the word - we looked at all the words that appear frequently in the ON, but that never appear in the GR, in order to understand what kinds of words the author found necessary to drop.

Word	Frequency	Word	Frequency
upon	75	table	31
least	65	astonishment	30
acquaintance	63	fancy	30
either	59	attempt	29
whose	59	dine	29
dare	53	beg	28
regard	53	depend	28
determine	47	highly	28
scarcely	45	satisfaction	28
ladyship	42	acknowledge	27
former	38	credit	27
put	36	thus	27
amiable	35	disposition	26
deal	34	exceedingly	26
design	32	praise	26
satisfy	32	pray	26
society	32	wholly	26

Table 3: Words that appear only in the ON

Table (3) shows that 14 out of the 34 words listed (ca. 35%) are too advanced for level B2. Some of the other words, though accessible to B2 learners, were replaced with easier synonyms. We also conducted an analysis on parts of speech and how they differ in the two data sets (Tab. 4).



PoS	More frequent in ON	Similar frquency	More frequent in GR
JJS adjective, superlative	X

Conclusions and further research

This study is a first step into the realm of text simplification and adaptation regarding graded readers for L2 learners. By conducting a difference analysis between the two texts, it was observed that at plot level the selection of scenes has no impact on the difficulty of a text. The text reuse detection software used, however, identified which parts of the plot have been preserved and which have been eliminated for the sake of a consistent, yet shorter, story line. It was observed that the beginning and the end of the novel were the parts that were adapted most faithfully.

The identification of reuse over the whole novel was also a step towards pinpointing where sentences were reused verbatim and where they were not. Where the sentences have undergone heavy changes, we can observe to what extent they were modified, how and why. At a sentence level, we noted that reducing the length of the sentences is a successful simplification strategy. A further study would have to be conducted to best understand how sentences were split or reduced, and consequently how the syntax of a sentence was affected by its shortening.

At a word level, the simplification of the text appeared to be dictated by the elimination and replacement of difficult vocabulary and certain parts of speech, such as comparative and superlative adjectives. The word length does not appear to be an indicator of difficulty. While it was observed that both the readability tests were based on sentence length as a parameter, only the ARI test, however, considers word length as another parameter. A test on the word-length distribution of the ON versus the GR shows that, in this case, the word length bears no importance in assessing the difficulty of a text. Further research would have to be conducted in order to learn if it is easier for an L2 learner to remember a word not because of its length, but because of its repeated presence in a text. The insights gained from this study will be useful in future work on automating the simplification process.

Introduction

The research described in these pages is made possible by openly available Classical texts and linguistic resources.

It aims at performing semi-automatic analyses of Paulus Orosius' (385-420 AD) most celebrated work, the *Historia adversum Paganos Libri VII,* against its sources. The *Histories*, as this work is known in English, constitute the first history (752 BC to 417 AD) to have been written from a Christian perspective. To do so, Orosius drew from earlier and contemporary authors, including the pagans Caesar, Vergil, Suetonius, Livy, Lucan and Tacitus, thus providing a rich narrative fraught with intertextual references to poetry and prose alike.

Orosius' vast network of references challenges automatic text reuse detection tasks both qualitatively and quantitatively. In fact, information retrieval algorithms face differences in reuse style –from verbatim quotations to paraphrase and allusions (Navarro, 1991)– and millions of words to sift through. To understand how Orosius reused texts, it is necessary to detect, extract, classify and evaluate all references and compare them to their sources, mindful of the balance between the *precision* of the results and their *recall* or number.

Related Work

Existing research on Orosius' sources for the *Histories* is scattered and often focusses on his relation to one author or work only, albeit acknowledging the full spectrum of sources (e.g. Coffin, 1936; Sihler, 1887). The size of the source- texts (see Table 1) makes it extremely difficult to produce a comprehensive and detailed manual exploration of *all* of Orosius' references.

"It would be burdensome to list all of the Vergilian echoes [...]" (Coffin, 1936, p. 237)

What Coffin describes as "burdensome" can be accomplished with machine assistance. To the best of our knowledge, no existing study, traditional or computational, has quantified and analysed the reuse habits of Orosius.

The *Tesserae* project, which specialises in allusion detection, is the most similar to the research presented here (Coffee, 2013). The main difference between the two projects is that while *Tesserae* "aims to provide a flexible and robust web interface for exploring intertextual parallels", the present project aims at using intertextual parallels to optimise detection tasks and refine existing linguistic resources. The difference between the technologies is that our software gives users more control over the algorithmic process, offering a choice between being guided by default settings or supervising the detection by adjusting search parameters.

Research Questions and Contribution

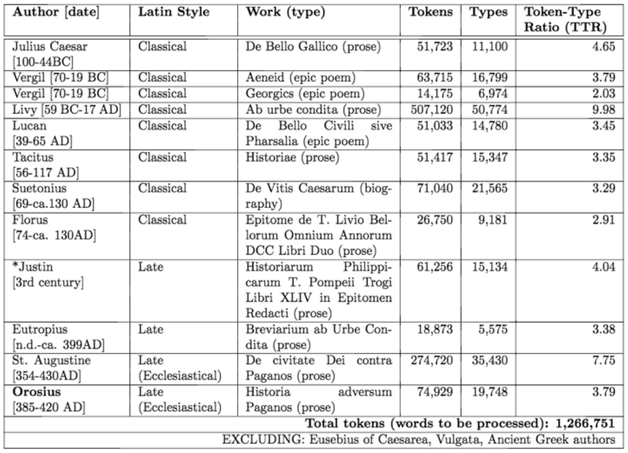
Our research began with the following questions: how does Orosius adapt Classical authors? Can we categorise his text reuse styles and what is the optimal precision-recall retrieval ratio on this large historical corpus? How does detection at scale affect performance?

In answering these questions, this project contributes new knowledge to both NLP and the Humanities. On the one hand, it serves as a case study for the testing of linguistic resources for Latin, and seeks to establish a workflow for the detection and evaluation of Latin text reuse at scale. On the other, it is the first attempt of its kind to analytically assess the reuse behaviour of Orosius and how his sources influenced his writing. This linguistic and literary analysis does not presume to subvert existing research on the topic but, rather, intends to facilitate philological enquiry by providing a detailed data-set from which inferences can be made, such as identifying unnamed sources or uncovering previously unnoticed reuses.

Data

All of the public-domain works for this study were downloaded from *The Latin Library*. We chose this collection over other analogous resources as it provides clean and plain texts (.txt), the format required by our text reuse detection machine TRACER.

Table 1 outlines the authors and works under investigation in chronological order. To give an idea of the size of the texts, the 'Tokens' column provides a total word-count for each work; the 'Types' column provides the total number of unique words; and the 'Token-Type Ratio' shows how often a type occurs in the text (e.g. a TTR of 3 indicates that for every type in a text there are three tokens. Generally, the higher the ratio the less linguistic variance in a text). This table reveals the language and challenges we should expect when detecting reuse. For instance, Caesar, Lucan and Tacitus share similar text lengths but Caesar has a higher TTR; this tells us that Caesar's text has less linguistic variety than Lucan and Tacitus. Conversely, if we look at Suetonius in comparison to Lucan and Tacitus, we notice a larger text but a similar TTR. This indicates a high linguistic variance in Suetonius' text, and one that can prove challenging for text reuse detection.



Author [date]	**Latin Style**	**Work (type)**	**Tokens**	**Types**	**Token-Type Ratio (TTR)**
Julius Caesar [100-44BC]	Classical	De Bello Gallico (prose)	51,723	11,100	4.65
Vergil [70-19 BC]	Classical	Aeneid (epic poem)	63,715	16,799	3.79
Vergil [70-19 BC]	Classical	Georgics (epic poem)	14,175	6,974	2.03
Livy [59 BC-17 AD]	Classical	Ab urbe condita (prose)	507,120	50,774	9.98
Lucan [39-65 AD]	Classical	De Bello Civili sive Pharsalia (epic poem)	51,033	14,780	3.45
Tacitus [56-117 AD]	Classical	Historiae (prose)	51,417	15,347	3.35
Suetonius [69-ca.130 AD]	Classical	De Vitis Caesarum (biography)	71,040	21,565	3.29
Florus [74-ca. 130AD]	Classical	Epitome de T. Livio Bellorum Omnium Annorum DCC Libri Duo (prose)	26,750	9,181	2.91
*Justin [3rd century]	Late	Historiarum Philippicarum T. Pompeii Trogi Libri XLIV in Epitomen Redacti (prose)	61,256	15,134	4.04
Eutropius [n.d.-ca. 399AD]	Late	Breviarium ab Urbe Condita (prose)	18,873	5,575	3.38
St. Augustine [354-430AD]	Late (Ecclesiastical)	De civitate Dei contra Paganos (prose)	274,720	35,430	7.75
Orosius [385-420 AD]	Late (Ecclesiastical)	Historia adversum Paganos (prose)	74,929	19,748	3.79
					Total tokens (words to be processed): 1,266,751
					EXCLUDING: Eusebius of Caesarea, Vulgata, Ancient Greek authors

Table 1. Overview of analysed texts. Excluded texts will be included in a second phase of the project. As we are still processing Justin we exclude him from the discussion for now.

Reuse Styles

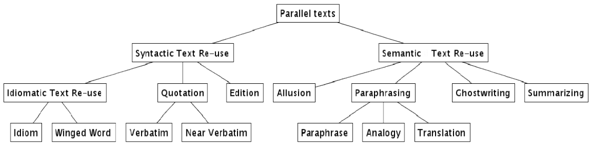


Figure 1. Graph illustrating reuse styles.

Orosius employs a variety of reuse styles, ranging from verbatim quotations to allusions and paraphrase (Navarro, 1991). The reuses are as short as two words (ibid.) or often invert the word order of the original text (Elerick, 1994).

Methodology

Our workflow makes use of three aids: a *TreeTagger* Latin language model for Part-of-Speech (PoS) tagging and lemmatisation (Schmid, 2013)– we chose to work with TreeTagger as, unlike other taggers, it comes with a pre-trained model for Latin (trained by Marco Passarotti); the *BabelNet 3.7* and *Latin WordNet* Latin lemma lists and synonym sets to support the detection of paraphrase and paradigmatically-replaced concepts; and TRACER, our text reuse detection machine**.**

First, the data is acquired and prepared: the texts are downloaded, cleaned through custom scripts and normalised. Next, the texts are lemmatised and tagged for PoS. Finally, we use TRACER to run detection tasks with different parameters in order to define the diversity of the reuses in the corpus.

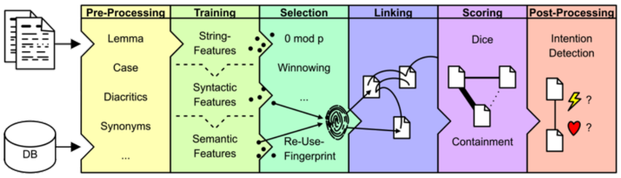

Figure 2: The six-step pipeline of TRACER (from left to right).

TRACER can split a detection task into six sub-tasks, each containing parameters that users can customise or (de)activate depending on the type of detection (see Figure 2). The reader will notice that the Pre-processing step also contains lemmatisation. This parameter is currently only available for English, hence our use of *TreeTagger* for Latin lemmatisation.

Results

Table 2 shows the distribution of *TreeTagger*'s PoS tags (in percentage) as rows across all authors analysed. Emerald-background cells indicate the most frequent PoS for an author (column), yellow-background cells the second-most frequent. Looking at the emerald cells, one can make two observations. First, we notice a higher use of punctuation during the shift from Classical to Late Latin, a result described in the full paper; second, we also notice the unsurprising predominance of the accusative case in most texts; accusative is the case of the object but is also used in expressions of time, place and space, in exclamations, after many prepositions and as the subject of the infinitive.

Table 2. Part-of-Speech distribution across all analysed authors.

Tagged and lemmatised text accounts for 93.1% of the corpus. A 7% of words could not be lemmatised due to typos in the text (e.g. missing white-spaces), which we will correct; similarly, some words could not be successfully tagged, as the lemmas are not included in the parameter file.

To run TRACER, the texts were initially segmentised by sentence. The average sentence length measured across the whole corpus is 31 words per sentence. A first experiment at the sentence-level failed due to the presence of very short reuses. For this reason, the segmentation was changed to a moving window segmentation with a window-size of ten, restricting TRACER's detection from entire sentences to smaller windows. In the *Selection* step (see Figure 2), we experimented with max-pruning and a PoS selection. However, max-pruning did not perform well because the sentences were too long compared to the scored overlap (see Figure 3). TRACER produced precise results but the recall was too low. For this reason, we changed to a PoS-based selection, which considered nouns, verbs and adjectives as relevant features, thus significantly increasing the recall and the overall quality of the results.

For the *Scoring* (see Figure 2), we used the resemblance score, which measures the ratio of overlapping features with the overall unique set of features of two alignment candidates. Figure 3 illustrates the results of the research thus far: we notice that just over 50% of all scored alignment pairs of two text passages have a four-word overlap only (e.g. nouns, verbs, etc.), and that 93.9% of all candidates have overlaps of 3, 4 or 5 words, indicating a fragmentary reuse style rather than block-copying.

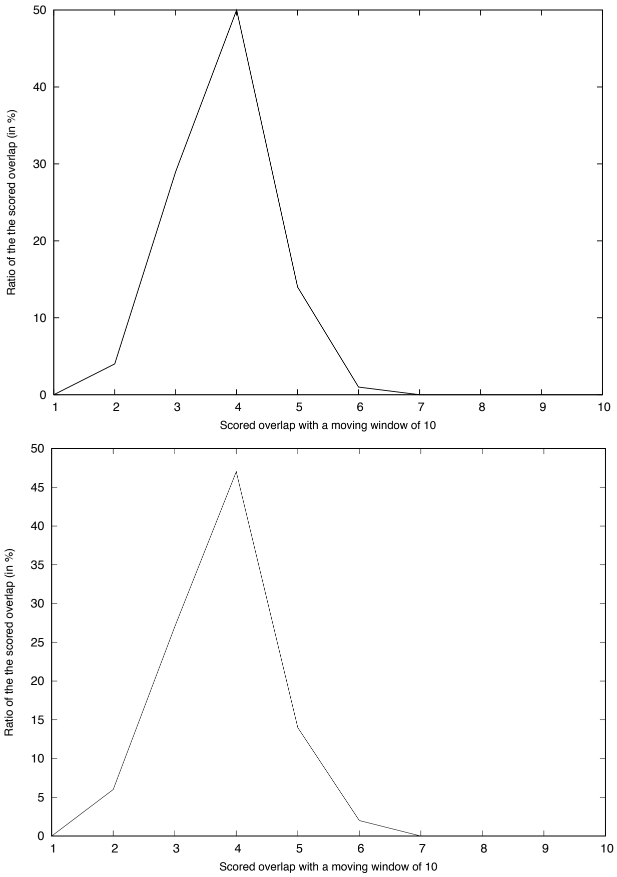

Figure 3. In these plots the x-axis represents a window of 10 words, while the y-axis the occurrence of the overlap in percentage. The left plot presents results identified across all texts; the right plot represents reuses identified in Orosius.

Orosius' plot in Figure 3 shows that over 45% of reuses identified overlap with source texts by 4 words, fitting the pattern identified across *all texts* displayed in the left plot of Figure 3.

Further Results

In the full paper, we describe the detection processes and how the computed results and known reuses correlate. We discuss the identification of paradigmatic relations against *BabelNet* and the *Latin WordNe*t for the detection of paraphrase and looser forms of reuse, and address the bridge between close and distant reading by providing a qualitative and quantitative study of Orosius' intertextual network. This includes a discussion on the reuse style of the author and a list of all reuses, both known and previously unnoticed by scholars. Furthermore, we describe how this research can contribute to the establishment of a Gold Standard for Latin lemmatisation and text reuse detection.

Limitations and Conclusion

This project aims at testing the stability of historical text reuse detection at scale, while analytically assessing the narrative and text reuse techniques of Orosius, our case study. We chose Orosius' *Histories* for its rich and diverse intertextual network, which tests the full spectrum of text reuse algorithms belonging to TRACER, giving us the opportunity to refine them against reuses identified in existing commentaries to Orosius, and to look at the whole array of reuses for further philological study into the degrees of influence his sources exerted upon his writing.

The retrieval accuracy of TRACER partly depends on the accuracy of the trained models of *TreeTagger* and on the *BabelNet* and *Latin WordNet* data. An error analysis is needed in order to verify the accuracy of our cleaned and automatically-tagged data, and to determine the effect of this incorrect tagging on text reuse detection. Depending on the outcome of this analysis, we will communicate the unlemmatised words to *TreeTagger* developers and/or consider re-tagging our corpus with a more advanced tagger, such as *LemLat* (Passarotti, 2007), incorporating curated linguistic resources (e.g. *Word Formation Latin* project) or even training a tagger on the different Latin types constituting our corpus.

Introduction

The advent of new funding streams and initiatives within broader humanities scholarship indicate that the collaborative research approaches have diffused beyond digital humanities. This paper presents the findings of the "Humanities Collaboration and Research Practices: Exploring Scholarship in the Global Midwest" project (HCRP), which examines the Humanities Without Walls initiative as a case study for how innovative, interdisciplinary humanities research draws upon models from digital humanities.

Background

The Humanities Without Walls (HWW) Global Midwest initiative supports collaborative research projects led by faculty from fifteen U.S. research universities in the Midwest. With its emphasis on multi-institutional, interdisciplinary collaboration and applied research, HWW Global Midwest presents rich research cases on the evolving nature of humanities research.

Literature

Studies of collaboration among digital humanities researchers and its impact on humanities scholarship have proliferated over the past decade (Siemens, 2009; Siemens, 2011; Deegan & McCarty, 2012; Given & Wilson, 2015). Focused studies of DH research practices also examine credit and authorship (Nowviskie, 2011; Nowviskie, 2012), infrastructure needs (ACLS, 2006, Edmond, 2015), and project management (Leon, 2011). Building upon this research, our study examines how the collaborative experimentations undertaken by HWW Global Midwest researchers influenced their research practices, data sharing, and final outputs.

Method

The project team conducted semi-structured interviews with 28 researchers funded by the first round of HWW Global Midwest awards. Participants were asked about project goals, collaboration development, tools used for project management, challenges, and research approaches.

The project team recorded and transcribed the interviews, and coded them in ATLAS.ti 7. Each transcription was coded multiple times for inter-coder reliability. This study applies a qualitative content analysis method that expands upon prior studies by Brockman et al. (2001), Palmer & Neumann (2002), and Palmer (2005), as well as a grounded theory approach (Corbin & Strauss, 2008).

Findings

Interviews with Global Midwest project awardees revealed a number of emerging practices and challenges common to the DH community and collaborative DH projects.

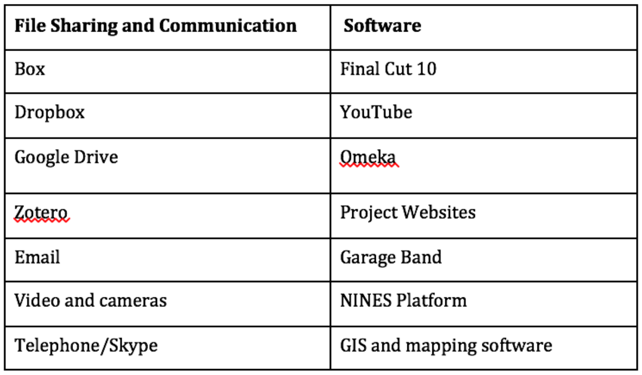
Project Workflows and Infrastructure

The interviewed participants identified many project challenges within the HWW program model. These included finding personnel and eligible collaborators, aligning IRB approvals, and funding coordination.

One participant summed up the sentiments of many on project management, saying "that was definitely a learning curve for all of us." But most deemed this learning curve worth undertaking.

Another key aspect of project workflows was the range of tools used by the HWW Global Midwest research groups (See Table 1). Tool selections ranged from cloud storage to unique platforms, including the software built for NINES and 18th Connect. But whether they used popular or specialized tools, one respondent's declaration captures their prevailing ethos: "We're using an existing infrastructure and we're applying it in a quite different way."

This process of translating tools to different uses is similar to the software adaptations seen in digital humanities research, and as scholars explore new ways to translate their research, they turn to multiple sources of expertise.



File Sharing and Communication	Software
Box	Final Cut 10
Dropbox	YouTube
Google Drive	Omeka

Email	Garage Band
Video and cameras	NINES Platform
Telephone/Skype	GIS and mapping software

Table 1: Tools for Research

Methods of Collaborative Analysis

Many research groups carefully developed methods of analysis in ways that resonate with cross-disciplinary approaches in digital humanities research. One respondent characterized a group's work as having "a lot of cross-fertilization of methodologies ... not so much about content." Another project planned to employ several methods of analysis, including a short film, a series of interviews, and a performance of dancers and scholars rolling around on the floor "because to resist was not going to happen." This type of collaborative process was described by one group as one that "unfolds in an uncertain and, in that sense, an egalitarian manner because no one knows yet what the thing will be…. You go on a hunch and you see where it takes you. That is typical of ethnography, but also, I think, of collaboration, as well." These dynamic and educational elements of collaboration proved to be key to partnerships.

Student Engagement

Several interviews related a need for research assistance and dedicated project management, and respondents repeatedly attested to the value of graduate assistants who shouldered the management burden of the projects, or the (unfulfilled) need for such students. Projects navigated the tension between relying on student labor and acknowledging the intellectual contributions of the students with varying degrees of success, with the most positive assessment citing student participation as the true catalyst for collaborative practice: "They're not just graduate students. They're fellow collaborators in the project at this point and they have tremendous resources of knowledge, you know. The multiplication is enormous. It's here that you really have the collaborating humanities."

Digital Dissemination and Curation

Respondents cited different formats for sharing their work, including performances, films, and websites as well as texts and presentations. Several respondents envisioned creating hybrid outputs, such as one respondent's plan "to create some kind of interactive map [and] ideally a repository of sounds." Another discussed the possibility of sharing interview data as a form of dissemination, noting that "we're still processing the data [and] deciding how to feature it… we're not tweeting the results or something like that." This response also highlights the complex characteristics of humanities data, and the multiplicity of factors that must be considered for data sharing and archiving.

Respondents also saw avenues for making broader impacts via use of different platforms. As one respondent explained, "I think we've contemplated scholarly output in the traditional platforms… whether they're online or in print, but we have contemplated getting research into the hands of stakeholders who are not scholars."

Collaboration and Credit

Many respondents were mindful of the importance of providing appropriate credit and recognition for project partners. One respondent noted that "for us, the notion of collaboration was built around the idea that both parties would be equally acknowledged." Negotiating appropriate credit, however, also can reveal moments of tension within projects. Another respondent observed that "there was a little bit of misunderstanding, and some disagreements […] had to do with who is being acknowledged for what."

Respondents differed on their views of co-authored publications. One respondent noted, "I didn't expect a lot of co-authoring, more of a co-design of the platform." Another viewed co-authorship as an important "end product collaboration." While discussion of evaluation for tenure and promotion were present within the interviews, they were not as prevalent as might be expected. Yet a key theme that emerged in the responses was that culture shifts within humanities disciplines are essential to advancing the acceptance of research collaborations and co-authorship in peer evaluation criteria.

Discussion and Conclusion

To bring emergent humanities research collaborations into dialogue with the digital humanities, we propose a set of recommendations as a foundation for fostering rigorous interdisciplinary collaboration:

Build stronger connections between teaching and research through engaging students in research collaborations: Student participation in digital humanities projects has been essential to the growth of DH research, and humanities scholars can similarly bring collaborative research practice into the classroom in ways that acknowledge and recognize the students' labor.

Experiment with new forms of dissemination that more accurately convey the full breadth of collaborative work: HWW Global Midwest researchers frequently sought new ways for disseminating interdisciplinary research findings: In the same way that digital humanities researchers employ new formats for publishing research data and findings, humanities scholars can experiment with new forms that reflect interdisciplinary approaches. Scholars should also consider protocols for establishing credit and co-authorship, such as a negotiated project charter that establishes workflows for the collaboration, standards for co-authorship and a grievance process.

Encourage a culture of sharing data and interim findings: Administrators are in a key position to encourage shifts in humanities research practices by encouraging and explicitly ascribing value to related intellectual activities. Both leaders as well as researchers can encourage a culture of sharing data and interim phase research outputs that recognize the complexities of the communities and types of data in humanities research.

Strategically expand institutional investments in humanities research collaborations in order to ensure research sustainability: To ensure sustainable collaborations, administrators may need to make financial and structural investments, and key to these decisions is understanding the motivations and requirements of multiple stakeholder groups represented within a project. For example, some team members may require explicit funding to dedicate allocations of their time, while other team members may need support staff assistance to manage budgets and project documentation. Another avenue is to leverage the embedded collaborative power of regional, national, and international consortia in order to ensure research sustainability.

These recommendations drawn from our findings suggest that the expansion and sustainability of innovative research collaborations in the humanities has critical intersections with the evolving research practices of digital humanities research.

Indigenizing the Digital Humanities: Challenges, Questions, and Research Opportunities

Jennifer Guiliano

Carolyn Heitman
heitman@unl.edu
University of Nebraska-Lincoln
United States of America

In 2010, 2.9 million Americans self-identified as American Indian or Alaska Native. In addition, another 2.3 million people reported as American Indian or Alaska Native in combination with one or more other races. There are 562 federally-recognized tribes in the United States with dozens of other state-recognized tribes awaiting federal recognition. Outside of the U.S. there are millions of other indigenous community members in lands far-flung. Native American Studies (on Native American Studies and its relationship to knowledge, see Fixico, 2013; Madsen, 2012; Meyers, 2016; and Warrior, 2014), an interdisciplinary field of study exploring the history, culture, politics, issues, and contemporary experience of these indigenous peoples of America, intersects with a number of issues related to access, preservation, and methodology that are problematized through the development and deployment of digital tools, methods and research. While tremendous work has been done around the preservation and access of analog materials within Native American communities (for an example of digital Native American projects, see the Chaco Canyon Research Archive), there has been much less attention paid to the ways in which digital objects (on analog to digital surrogates, see the *Protocols for Native American Archival Materials*; on digital repatriation, see Christen, 2011; Colwell-Chanthaphonh, 2011; Colwell, 2015; and Runde, 2010), practices, and methods function within Native communities and through Native American Studies scholarship. With the exception of the Murkutu content management system which originated with the Warumungu Aboriginal community in the Central Australian town of Tennant Creek, digital humanities researchers and developers have been largely separate from Native American Studies– for example, it is only in the last year or so that we have begun to see digital humanities represented at Native American Studies conferences (e.g. Ethnohistory, Native American and Indigenous Studies Association, etc.) or within topical sub-panels at professional gatherings like the American Studies Association, the Modern Language Association, or the American Historical Association. There are hundreds of scholars actively working at dozens of American Indian, Native American, and Indigenous studies programs in addition to scholars working in humanities departments like literature, history, anthropology, archeology, etc. While museum, library, and archival communities have digitized Native cultural objects, literature, and music, there has been just cursory use of these materials within the larger digital humanities research landscape outside of digital archives or digital anthropology/archeology contexts. This submission opens by exploring a handful of individual projects that have leveraged Native materials to highlight how Native American studies scholars might critique the use and contextualization of tribal materials. Potential projects for exploration include Performing Archive: Edward Curtis + "the vanishing race" , the Indigenous Digital Archive, and the Native American Images Project. The digital humanities community has done little to inform itself of the unique issues associated with research and teaching by and in the Native American context. This knowledge has not been integrated for five reasons: 1) funding for Native American studies research institutionally has focused on the production of traditional scholarly products (e.g. monographs); 2) Native American studies as a discipline has remained underfunded institutionally which bars many institutions from hiring staff, faculty, and tribal members to work together to teach and research; 3) funding for cultural heritage organizations including tribal archives, libraries, and museums, has focused on preservation and access to analog materials (on intellectual property issues associated with analog to digital Native materials, see Anderson, 2005; and Brown and Nicholas, 2012) only, rather than embracing the spectrum of digital and analog materials that document Native life; 4) the diversity of academic disciplines who participate in Native Studies is broad and, as such, lends itself to fragmentation and a lack of information exchange about digital projects, tools, methods, and pedagogy; and 5) Digital Native studies most frequently is only encountered by scholars and community members at the end of the development cycle as the project is released and they begin to encounter "actual" users. As a result, there do not exist any best practices, guidelines, or even suggestions about the process of working in digital environments with Native American communities. Archaeologists and museum professionals have made the furthest strides in attempting to address engagement with tribal communities and research (on issues of information architecture and archiving in indigenous contexts, see Powell and Aiken, 2010; Cushman, 2013; Senier, 2014; Christen, 2012; and Joffrion and Fernández, 2015), yet that work has not widely proliferated among the interdisciplinary humanities nor the digital humanities more generally. As a result, each digital humanist (and humanist) must start from scratch and negotiate every encounter without guidance or lessons learned from those who have attempted integration of the digital with Native American Studies before.

Additionally, because these conversations have been focused mainly on individual projects or on knowledge management generally (e.g. the Murkutu Project and the Intellectual Property Issues in Cultural Heritage Protocol), the cross-pollination of an interdisciplinary community of digital researchers with tribal communities, cultural heritage organizations, and academic scholars has been significantly underdeveloped. Thus, it is not surprising that there are only a handful of funded digital projects documenting Native American life: the American Indian Treaties Portal, a digital collection of the final texts of 366 of the 375 American Indian treaties recognized by the United States Department of State, and the digitized Journals of Lewis & Clark Expedition created in partnership with the Center for Digital Research at the University of Nebraska Lincoln. Mark of the Mississippians: A Multi-Platform Digital Media Project (Cahokia Mounds Museum Society) and Meeting the Earthworks Builders, a flashbased video game are currently being developed by the Ohio State University.. Additionally, NEH Public Programs just funded Indians of the Midwest, an educational website focused on recent scholarship on Native peoples and the Newberry Library Collection.

The barriers to digital fluency in Native American studies are varied and include such obstacles as cultural rules regarding access to sensitive materials, the advanced technical expertise that software and hardware often requires beyond basic digitization, the costs of digital infrastructure and proprietary license fees, and issues of community engagement and trust that might limit the display of digital materials about Native peoples. It might be tempting to assume that the uptake of digital humanities method and pedagogy in the academic, cultural heritage, and tribal communities is one of lack of information or funding, but in fact the digital humanities researchers included as part of the Digital Native American and Indigenous Studies project are finding that it is also the cultural barriers to access, display, and analysis across differing types of digital materials that are challenging our ability to leverage digital tools, resources, and approaches.

Digital Humanities articulates three parallel interdisciplinary commitments to “openness”: 1) a commitment to open access publishing; 2) a commitment to open access/open source software development; and 3) a commitment to open access data. While the first two trends have received deep and lasting attention via scholarly publishing and digital commons enterprises and the open source development movement promoted by github and other code repositories, the commitment to open access data has been largely undertheorized. Using case studies of Digital Humanities projects that have been developed using Native American and Indigenous content, this submission suggests that Native and Indigenous content complicates the current technical application of open source development driven by digital aggregators and application programming interface development. By highlighting ethical issues around the use, reuse, and distributed architectures encouraged by common digital humanities technologies, this submission suggests that the rhetoric and practice of the open access data movement obscures both Native agency in determining the use of community materials as well as the role of technical determinism in proliferating the violence of colonial archives on Native communities. Questions this submission engages with include: How do we deal with born-digital research data in Native American and Indigenous contexts? How do we as scholars responsibly engage in digital research in Native communities? How do organizations and institutions navigate the cultural, legal, and ethical contexts of the communities whose objects they hold? How can free and open source software solutions be leveraged to build community engagement? Finally, what might be recommended for tribal communities who desire to launch their own digital projects but may have concerns about resources, access, infrastructure, and preservation?

GutenTag: A User-Friendly, Open-Access, Open-Source System for Reproducible Large-Scale Computational Literary Analysis

Adam Hammond
adam.hammond@utoronto.ca
University of Toronto, Canada

Julian Brooke
julian.brooke@unimelb.edu.au
University of Melbourne, Australia

Introduction

GutenTag is a cutting-edge resource that allows literary researchers of all levels of technical expertise to perform large-scale computational literary analysis. It allows users to build large, clean, highly customized worksets and then either analyse them in-system or export them as plain text or richly-encoded TEI. It has been built from the ground up by literary scholars for literary scholars: rather than relying on off-the-shelf tools poorly suited to the domain of literature, we have developed many of the components ourselves based on the specific demands of literary research. GutenTag is fully open-source, its analyses are based on entirely open corpora, and researchers can save and distribute all the parameters of their analyses, allowing for unprecedented reproducibility of research in a field plagued by siloed corpora. GutenTag is easy to use, permitting casual non-programmers to perform complex computational literary analysis via an online interface, while offering additional offline customization options to more advanced users. Although GutenTag was initially designed to facilitate our own research in polyvocality and dialogism, we show here that it can be leveraged to intervene in pressing debates unrelated to our specific research, such as the discussion surrounding Matthew Jockers's analysis of gender in *Macroanalysis*.

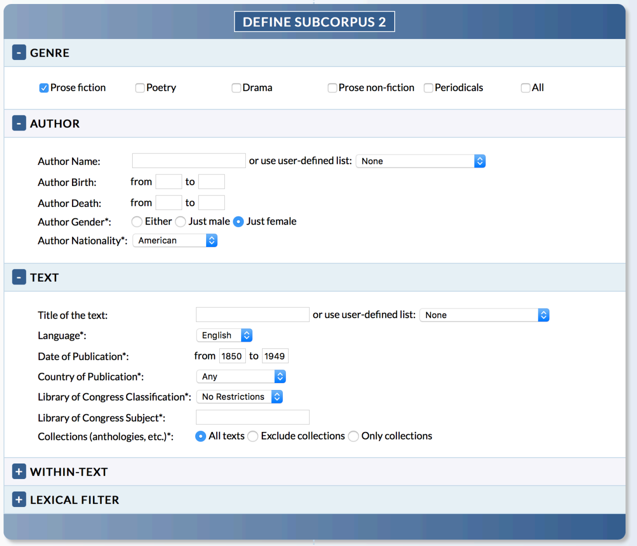
Overview of GutenTag

The system has grown considerably since our initial proposal, presented to an audience of computer scientists (Brooke et al., 2015). Below, we review the main features of the software with particular emphasis on recent improvements.

Interface: GutenTag is primarily accessed through an HTML GUI, accessible via the web or as a downloadable tool (both can be accessed from http://www.projectgutentag.org). In offline mode, the configuration files can be saved and loaded, and additional lexicons and other lists used for analysis can be specified by the user. A Python API is also included.

Corpora: The original version supported only the 2010 image of Project Gutenberg USA, but we have expanded support to all texts from Project Gutenberg USA as well as Project Gutenberg Canada and Australia, which include many additional texts published after 1922 and still under copyright in the USA.

Metadata: Document collections of interest can be defined using a variety of metadata tags. These include metadata provided by Project Gutenberg (title, author, author birth, author death, and, for some texts, Library of Congress classification and subjects). We have added genre (fiction, non-fiction, poetry, drama), determined using a sophisticated machine classifier, as well as author and text information (author gender, author nationality, publication date, publication country, single work or collection, etc.) derived from (mostly) unstructured resources including Wikipedia and the texts themselves.



DEFINE SUBCORPUS 2

- GENRE

☑ Prose fiction ☐ Poetry ☐ Drama ☐ Prose non-fiction ☐ Periodicals ☐ All

- AUTHOR

Author Name: ____ or use user-defined list: None
Author Birth: from ____ to ____
Author Death: from ____ to ____
Author Gender*: ○ Either ○ Just male ● Just female
Author Nationality*: American

- TEXT

Title of the text: ____ or use user-defined list: None
Language*: English
Date of Publication*: from 1850 to 1949
Country of Publication*: Any
Library of Congress Classification*: No Restrictions
Library of Congress Subject*: ____
Collections (anthologies, etc.)*: ● All texts ○ Exclude collections ○ Only collections

+ WITHIN-TEXT

+ LEXICAL FILTER

Figure 1: The GutenTag interface, showing the creation of a workset based on advanced metadata (Genre, Author Sex, Author Nationality, Date of Publication)

Text cleaning and tokenization: Sophisticated regex-based heuristics are applied to remove meta-text elements related to Project Gutenberg before, after, and sometimes within the text boundaries. Literature-specific tokenization is provided, preserving important information needed for downstream analysis.

Structural Tagging: This module identifies the main structural elements of the texts. First, heuristics are used to identify the likely boundaries between front matter, body, and back matter. Identification of structure within the main text is driven primarily by the identification of headers, and fully supports recursive structures including entire embedded texts which can have their own front and back matter separate from that of the anthology. Structural tagging is sensitive to genre: in the context of fiction, we identify parts, chapters, and speech; for poetry, we identify poems, cantos, stanzas, and lines; for drama, we identify acts, scenes, speakers, speech, and stage directions.

Lexical tagging: GutenTag includes lemmatization and POS tagging. There are several built-in lexicons which capture semantic and stylistic distinctions, and users can define their own lexicons, including multiword lexicons. Most recently, and most relevant to our case study below, we have added our own state-of-the-art literature-specific named entity recognition system (LitNER) which bootstraps from context-based clustering of common named entities to distinguish previously unseen people and locations from other named entities (Brooke et al. 2016b). For fiction, we group individual person names into collections of characters, and then assign speech events to these characters in the vicinity, using efficient, rule-based logic inspired by work in He et al. (2013). We identify the indicated sex of these characters primarily using large lists of names and titles; when a name does not appear on our list, we fall back to matching common sex-indicative character n-grams automatically derived from those lists (e.g. names ending with "a" tend to be female).

TEI output: When corpus output is required, we use XML-based TEI format as the default output format when structure (rather than simply tokens) is requested.

Figure 2: The GutenTag interface, showing in-system options for analysis via textual measure

Analysis: In addition to building corpora for exporting, GutenTag users can directly compare the distribution of relevant lexical tags or other textual metrics across multiple corpora as defined in the metadata filtering phase. The latest version includes a selection of standard textual metrics (e.g. average sentence length), part-of-speech based metrics such as lexical density, and metrics that rely on structural/lexical tagging, such as the amount of dialogue and the amount of dialogue that has been assigned to female characters. Advanced users can easily define their own textual metrics using Python; these then become available through the main interface. We also welcome requests for metrics from the DH community.

Research Applications

GutenTag was initially developed to facilitate our own research in literary dialogism (Hammond et al. 2016, Brooke et al. 2016a). GutenTag allows us to perform three crucial steps in our research process: first, to build customized corpora (a set of novels published from 1880-1950, for which it yields 4,088 results); second, to identify passages of character speech in each novel and assign a unique character to each passage of speech; and third, to calculate a measure of dialogism for each text using an algorithm based on our six-style approach (Brooke et al. 2016a). Further, GutenTag allows us to save our workflow in a parameter file so that it can be reproduced by other researchers.

GutenTag is designed as a general system, however — not merely as a vehicle for our specialized research. We thus present an example of how it can be employed (by a non-programmer) to investigate a prominent debate in Digital Literary Studies, Matthew L. Jockers's discussion of gender and authorship in Macroanalysis. Jockers argues that female authorship can be predicted reliably through topic modelling, based on the presence of themes that "correspond rather closely to our expectations and our stereotypes" such as "Affection and Happiness," "Female Fashion," and "Infants" (Jockers 2013). A reader might respond to Jockers's analysis by querying his assumptions about literary authorship; specifically, his failure to distinguish between authors and characters. Suppose that female characters were just as likely to discuss "Female Fashion" in novels written by men as those written by women, but that female authors tended to include more female character speech in their novels, as Muzny et al. (2016) suggest. If this were so, Jockers's findings would not confirm stereotypes about female authorship, but simply reveal the tendency of female authors to include more female voices in their texts than men.

GutenTag is uniquely suited to investigating such a question. Its advanced metadata and sophisticated lexical tagging allow it to easily and rapidly analyze the question of female character speech in a large corpus of English-language novels.

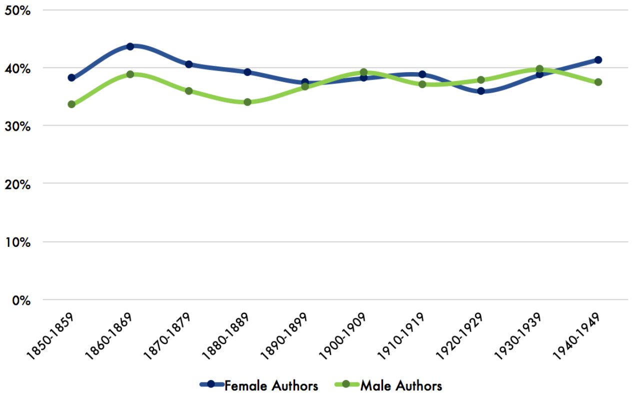

Figure 3: Mean proportion of text which Is dialogue in prose fiction, female vs. male authors, 1850-1949.

Sample sizes as follow, in number of texts. 1850-1859: 53 female, 97 male. 1860-1869: 86 female, 128 male. 1870-1879: 110 female, 137 male. 1880-1889: 122 female, 262 male. 1890-1899: 221 female, 583 male. 1900-1909: 299 female, 975 male. 1910-1919: 354 female, 960 male. 1920-1929: 148 female, 656 male. 1930-1939: 77 female, 413 male. 1940-1949: 52 female, 135 male.

Figure 3 shows that female authors in the twentieth century included approximately the same amount of dialogue as a proportion of total text length as male authors, but that in the latter half nineteenth century, they included approximately 5% more than men. Since Jockers focuses on the nineteenth century, this finding alone might impact his conclusions.

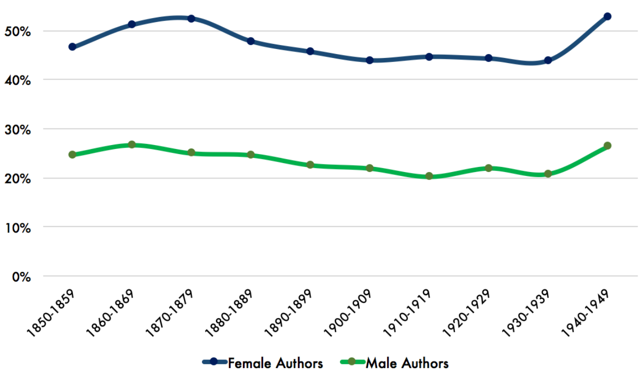

Figure 4: Mean proportion of dialogue allotted to female characters in prose fiction, female vs. male authors, 1850-1949

Sample sizes as follow, in number of texts. 1850-1859: 53 female, 97 male. 1860-1869: 88 female, 128 male. 1870-1879: 110 female, 137 male. 1880-1889: 122 female, 261 male. 1890-1899: 220 female, 583 male. 1900-1909: 300 female, 795 male. 1910-1919: 354 female, 960 male. 1920-1929: 148 female, 655 male. 1930-1939: 77 female, 413 male. 1940-1949: 54 female, 135 male.

As Figure 4 shows, GutenTag supports Muzny et al.'s contention that female novelists incorporate far more (approximately twice as much) female dialogue compared with male novelists. The finding that the proportion of female dialogue decreased from the late nineteenth to the mid-twentieth century, in both female and male authors, is one that bears further investigation — particularly in relation to the emergence in that period of popular genres, such as children's literature, Westerns, and romance novels.

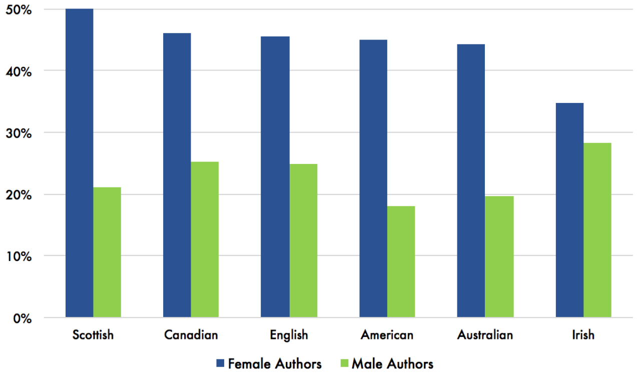

Figure 5: Mean proportion of dialogue allotted to female characters in prose fiction, female vs. male authors, by nationality, 1850-1949

Sample sizes as follow, in number of texts. Scottish: 31 female, 80 male. Canadian: 49 female, 78 male. English: 339 female, 1308 male. American: 572 female, 1545 male. Australian: 38 female, 104 male. Irish: 21 female, 92 male.

In Figure 5, we employ GutenTag's ability to filter results by author nationality. The marked discrepancy between proportion of female dialogue in male authors from England and the United States again suggests the need for an further investigation of genre; for instance, whether the American preference for male-centred genres like the Western might explain the result. Looking at GutenTag's fine-grained outputs, we observe that the texts with the lowest proportion of female dialogue are those directed at a young male audience (especially adventure fiction for boys) while those with the highest proportion consist largely of fiction for young women (L. M. Montgomery's Anne of Green Gables devotes over 90% of its dialogue to female characters). These findings might prompt our hypothetical researcher to engage in a smaller-scale study of the representation of gender in children's literature. Because all texts in GutenTag are accessible to users, it easily accommodates such movements from large-scale analysis to close reading.

Conclusion

GutenTag allows researchers of all levels of technical expertise to perform advanced large-scale literary analysis, as well as to independently test the hypotheses and conclusions of prominent research in the field. Our case study further shows how the integrated, end-to-end GutenTag system allows users to raise new research questions in the course of their analyses (such as the correlation between the emergence of children's fiction and the proportion of female dialogue) and then, since all its corpora are accessible, to shift scales and explore these questions through close reading.

Don’t Get Fooled by Word Embeddings—Better Watch their Neighborhood

Johannes Hellrich
johannes.hellrich@uni-jena.de

Udo Hahn
udo.hahn@uni-jena.de
Friedrich Schiller University Jena, Germany

Word embeddings, such as those created by the word2vec family of algorithms (Mikolov et al., 2013), are the current state of the art for modeling lexical semantics in Computational Linguistics. They are also getting more and more popular in the Digital Humanities, especially for diachronic language research (see below). Yet the most common methods for creating word embeddings are ill-suited for deriving qualitative conclusions since they typically involve random processes that severely limit the reliability of results—repeated experiments differ in which words are deemed most similar with each other (Hellrich and Hahn, 2016a,b). We provide a short overview of different embedding methods and demonstrate how this lack of reliability might affect the outcome of experiments. We also recommend a more recent embedding method, SVD$_{\text{PPMI}}$ (Levy et al., 2015), which seems immune to these reliability problems and, thus, much better suited (not only) for the Digital Humanities (Hamilton et al., 2016).

Word embeddings are a form of computational distributional semantics for determining a word’s meaning "from the company it keeps" (Firth, 1957, p. 11), i.e., the words it co-occurs with. The word2vec algorithms have their origin in heavily trimmed artificial neural networks. Their skip-gram negative sampling (SGNS) variant is widely used because of its high performance and robustness (Mikolov et al., 2013; Levy et al., 2015). Two other word embedding methods were inspired by word2vec: GloVe (Pennington et al., 2014) tries to avoid the opaqueness stemming from word2vec’s neural network heritage through an explicit word co-occurrence table, while the more recent SVD$_{\text{PPMI}}$ (Levy et al., 2015) is built upon the classical pointwise mutual information co-occurrence metric (Church and Hanks, 1990) enhanced with pre-processing steps and hyper-parameters from the two aforementioned algorithms.

There are two sources of randomness affecting the training of SGNS and GloVe embeddings: First, the random initialization of all word embedding vectors before any examples are processed. Second, the order in which these examples are processed. Both can be replaced by deterministic alternatives, yet this would simply replace a random distortion with a fixed one, thus providing faux reliability only useful for testing purposes. In contrast, SVD$_{\text{PPMI}}$ is conceptually not affected by such reliability problems, as neither random initialization takes place nor is a relevant processing order established.

Word embeddings can be compared with each other to measure the similarity of words (typically by cosine)—an ability by which they are often assessed (see e.g., Baroni et al. (2014) for more details on their evaluation). In the Digital Humanities, they have already been used to directly track diachronic changes in word meaning by comparing representations of the same word at different points in time (Kim et al., 2014; Kulkarni et al., 2015; Hellrich and Hahn, 2016c; Hamilton et al., 2016). They can also be used to track clusters of similar words over time and, thus, model the evolution of topics (Kenter et al., 2015) or compare neighborhoods in embedding spaces for preselected words (Jo, 2016). Besides temporal variations, word embeddings are also suited for analyzing geographic ones, e.g., the distinction between US American and British English variants (Kulkarni et al., 2016). In most of these approaches, the local neighborhood of selected words in the resulting embedding spaces, i.e., words deemed to be most similar with a word in question, are used to approximate their meaning at a given point in time or in a specific domain. Yet the aforementioned randomness leads to a lack of replicability, since repeated experiments using the same data set and algorithms result in different neighborhoods and might thus mislead researchers.

To investigate this problem, we trained three models each with three embedding methods, i.e., GloVe and SVD$_{\text{PPMI}}$, on the same data set and measured how they differ in their outcomes on word neighborhoods. Our data set consists of 645 German texts from the 19th century that are part of the *Deutsches Textarchiv Kernkorpus* (DTA) [German text archive core corpus] (Geyken, 2013; Jurish, 2013). The DTA contains manually transcribed texts selected for their representativeness and cultural importance; we use the orthographically normalized and lemmatized version, with casefolding. We evaluate the word embedding methods by calculating the percentage of neighbors for the most frequent nouns in the DTA on which all three models of each method agree. Overall, SVD$_{\text{PPMI}}$ provides perfect reliability, while the other two embedding methods lack reliability, SGNS dramatically so, which is consistent with our prior studies on word2vec (Hellrich and Hahn, 2016a,b).
Figure 1 shows the reliability for each model evaluated against the 1000 most frequent nouns in the DTA when their first ten closest neighbors (from one up to ten) are compared. Larger neighborhood size had a small positive effect on the reliability of SGNS and GloVe, yet is clearly unable to mitigate the inherent unreliability of these methods. A small inverse effect can be observed when the number of

the most frequent nouns is modified while keeping a constant neighborhood size of five, as displayed in Figure 2. Finally, Table 1 provides differing neighborhoods for *Herz* [heart] as a qualitative example. In this case, though not necessarily in general, SGNS models featured a more anatomical view (e.g., *bluten* [to bleed]), whereas GloVe models uncovered metaphorical meaning (e.g., *gemüt* [mind]) and SVD$_{\text{PPMI}}$ came out with a mix thereof. Using SGNS or GloVe models to assess a word's meaning can be strongly misleading, as evidenced by e.g., three SGNS models representing three different runs under the same experimental set-up. They lead to completely different semantic characterizations of *Herz* [heart], since two provide negatively connotated words (e.g., *schmerzen* [pain]) as closest neighbors, whereas the third provides a more positive impression (e.g., *herzen* [to caress]).

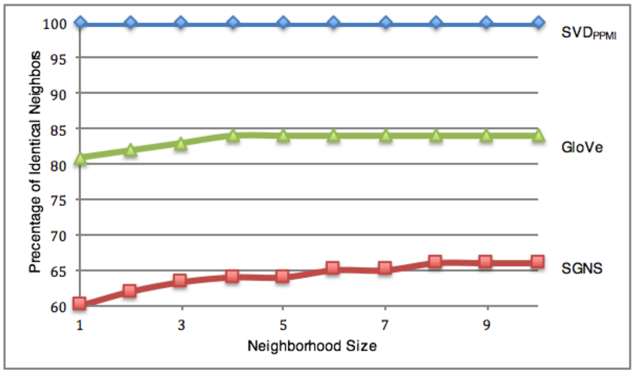

Figure 1: Reliability of different word embeddings as percentage of identical neighbors among the one to ten closest neighbor(s) to the 1000 most frequent nouns.

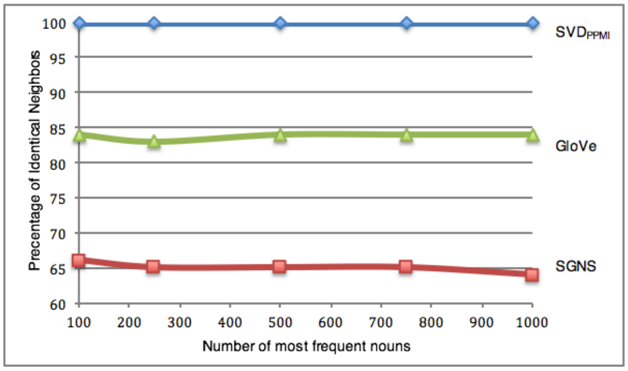

Figure 2: Reliability of different word embeddings as percentage of identical neighbors among the five closest ones for the 100 to 1000 most frequent nouns.

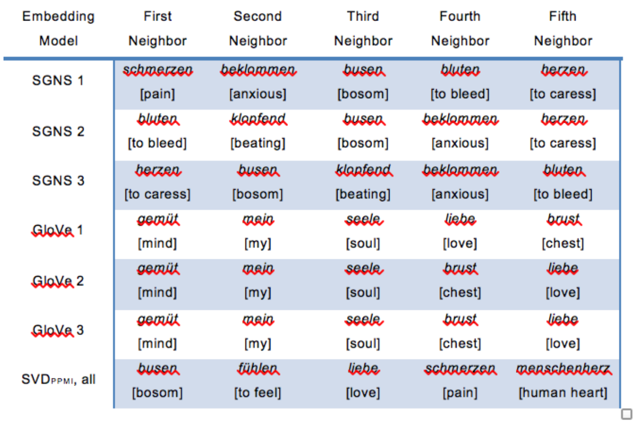

Embedding Model	First Neighbor	Second Neighbor	Third Neighbor	Fourth Neighbor	Fifth Neighbor
SGNS 1	*schmerzen* [pain]	*beklommen* [anxious]	*busen* [bosom]	*bluten* [to bleed]	*herzen* [to caress]
SGNS 2	*bluten* [to bleed]	*klopfend* [beating]	*busen* [bosom]	*beklommen* [anxious]	*herzen* [to caress]
SGNS 3	*herzen* [to caress]	*busen* [bosom]	*klopfend* [beating]	*beklommen* [anxious]	*bluten* [to bleed]
GloVe 1	*gemüt* [mind]	*mein* [my]	*seele* [soul]	*liebe* [love]	*brust* [chest]
GloVe 2	*gemüt* [mind]	*mein* [my]	*seele* [soul]	*brust* [chest]	*liebe* [love]
GloVe 3	*gemüt* [mind]	*mein* [my]	*seele* [soul]	*brust* [chest]	*liebe* [love]
SVD$_{\text{PPMI}}$, all	*busen* [bosom]	*fühlen* [to feel]	*liebe* [love]	*schmerzen* [pain]	*menschenherz* [human heart]

Table 1: Neighborhoods for Herz [heart] as provided by different word embedding models.

The lack of reliability we observed is definitely problematic, as often, especially for illustrations, rather small neighborhoods are used to gauge a word's meaning. Our experimental data lead us to caution when SGNS or GloVe word neighborhoods are used for uncovering lexical semantics. We recommend SVD$_{\text{PPMI}}$ instead, as its results are of similar quality yet guaranteed to be reliable (Levy et al., 2015; Hamilton et al., 2016). Consequently, we adapted our ongoing research activities on tracking language change to these insights and replaced the results of earlier work with SGNS (Hellrich and Hahn, 2016c) by data based on SVD$_{\text{PPMI}}$ (Hellrich and Hahn, 2017).

Prosodic Clustering via Cosine Similarity of Sound Sequence Inventories

Christopher Hench
chench@berkeley.edu
UC Berkeley, United States of America

Much of the discourse on music and rhythm before the time of the Minnesänger ('love singers', composers of German love poetry and songs around 1200) considers Latin chant. Alberic of Monte Cassino, active one century earlier than the Minnesänger, was the first to address rhythmic poetry in a music theory context in his treatise *De rithmis*, but he crucially does not mention rhyme, preferring to distinguish differing treatments of syllable length (Davis, 1966; Fassler, 1987). Not until the 12th and 13th centuries do treatises emerge elevating rhyme as integral to rhythm (Mari, 1899). A clear trend emerges in the period directly preceding MHG's *Blütezeit* (intense period of literary production)—theorists deemphasize syllable length in favor of a greater emphasis on syllable count and rhyme. After the Minnesänger, the *Meistersänger* ('master singers') of the German early modern period believed they were continuing the famed tradition of the medieval *Minnesänger* by focusing their art on syllable count and placement (März, 2000). For the Meistersänger, this focus was less a reflection of the increasing emphasis on music in poetic texts beginning in the 14th century, and more a method to reproduce the work of the medieval poets as closely as possible.

Unfortunately, we know very little about rhythm and sound in vernacular German poetry between these Latin treatises and the songs of the Meistersänger. Yet as both surrounding periods point to the syllable as fundamental to the composition of rhythmic poetry, we suggest the syllable as a rich source of formal information, both aesthetic and stylistic, which can serve as a formal alternative to common lexical methods in quantitative analyses, and which can help disambiguate the tension between form and content when subsequently compared to lexical methods. Although the broader project encompasses several analyses of sound and rhythm, this paper focuses on one application in particular—contrasting and visualizing the different uses of prosodic sound in the medieval German corpus (written in a stage of the language referred to as Middle High German (MHG)) through cosine similarity measurements of prosodic feature sequence *tfidf* (term frequency inverse document frequency) matrices.

Fortunately, although no unambiguous accounts of MHG rhythm survive, the manuscripts do provide phonologic evidence. We know the language of MHG had vowels of varying sonority, was structured in syllables, and was composed of words, regardless of the dialect or orthography (Paul et al., 2007). While we know that long vowels, and thus varying heavy syllables, did exist, we cannot be sure how the authors intended them in verse. Metrical systems have also been theorized, but orthographic variation in long vowels and theoretical disputes allow only limited, though productive, investigations (Estes and Hench, 2016).

To consider rhythm and sound broadly across the entire MHG corpus we turn to a relatively simple NLP technique in calculating the cosine similarity between *tfidf* inventories of texts. Yet our 'terms' are not words, but rather syllable features. For guidance, we turn to biology and new methods for clustering DNA sequences (Volkovich et al. 2005; Tomović et al. 2006; Maetschke et al. 2016). A technique employed in this scholarship takes n-gram samples of DNA strands. Similarly, we propose taking n-gram samples of *prosodic* features, primarily syllable features (closed 'C', open 'O', and word boundaries '-'), and constructing something resembling a *tfidf matrix.* Because our syllabification methodology is a combination of the sonority sequencing principle (Jesperson, 1904) and onset maximization and legal initials (Venneman, 1995), our syllabification method does not bias a dialect or orthography, but is accurate for most variants of MHG (Estes and Hench, 2016). Our features are coded as below:

Ein ritter sô gelêret was, (*Der Arme Heinrich*, l. 1-2)
C-CC-O-OOC-C-X

daz er an den buochen las,
("There was a knight so learned, that he read in the books")
C-C-C-C-OC-C-1

Where 'C' is a closed syllable (ends in a consonant), and 'O' is an open syllable (ends in a vowel). Hyphens for word boundaries account for the stress-initial tendency of MHG. Numbers at the end of a line mark end-rhyme; the number is how many lines back the rhyme was seen and an 'X' stands for the beginning of a rhyme pair (it was not seen in the past lines). All sequences for a text are then joined:

C-CC-O-OOC-C-X-C-C-C-C-OC-C-1 [...]

N-grams with an *n* of 10 are taken from this long string, going between lines for coherency, resulting in a tfidf feature matrix with feature strings of length 10. Most choices of *n* yield similar results; a lower *n* simply results in a higher degree of similarity between every text. With every increase of *n*, this similarity inevitably decreases. An *n* of 10 allows for sequences of around three to four words to be compared across texts.

A match between the MHG epics *Parzival* and *Tristan* illustrates these features:

Ist zwîvel herzen nâchgebûr
("If the heart lives with doubt",) (*Parzival* l. 1)

C-OC-CC-COC-Xvon sinen schulden ungemach
([which had] suffered due to him) (*Tristan* l. 769)
C-OC-CC-COC-X

This match implies that the number of words and syllables per word are the same, the syllable quality patterning is the same, and importantly, the rhyme is the leading rhyme (in a pair). Because the sequence matches for 13 features including word boundaries, this will create three additional matches in the tfidf inventories when the 10-gram samples are taken. While these two lines also happen to share the same scansion in the Heusler tradition, we cannot assume that every match also bears the same scansion, as more than phonology dictates metrical value (Heusler, 1956). A visualization of these cosine similarity relationships between 595 verse texts from the *Mittelhochdeutsche Begriffsdatenbank* is available online (MHDBDB, 2016).'

One may object: what if this method does not abstract *enough*? What if the syllable sequences texts share are exact lexical matches? In order to determine to what degree this prosodic sequencing approach is lexically driven, we undertake two separate measures: 1) correlation and rank correlation between the suggested formal method and a traditional lexical method, and 2) on the basis of two sample texts, we remove every possible lexical match in the inventory of sound DNA matches via a Levenshtein distance threshold, and recalculate the cosine similarities.

To account for genre intertexualities or formulas affecting this measure we take a prototypical Arthurian romance *Iwein* and its 10 most similar texts. When considering texts between an oral and written culture it is important to recognize formulaic language as influential on genre, a field pioneered by Adam Parry and Milman Parry for Homeric verse (Parry and Parry, 1971); in the Germanic tradition Franz Bäuml (Bäuml, 1972; 1976). For each n-gram sequence match in *Iwein* to each of the 10 most similar texts, we evaluate the corresponding lexical strings of the matching prosodic sequences with the Levenshtein ratio (the Levenshtein ratio is defined by the Levenshtein distance (edit distance) divided by the alignment length), if the ratio is > .85, the prosodic sequence is removed from *Iwein*, e.g., 'wîp unde man â' ≈ 'wîp unde man ze' has a Levenshtein ratio > .85, so all sequences of '-C-CO-C-XO' are removed from *Iwein*. Removing sequences of close lexical matches in *Iwein* removes 40.65% of the prosodic sequence feature strings, yet correlation of text cosine similarities before and after removal remains high at .991, and top 10 and top 20 overlap are 60% and 70% respectively, implying that text similarities are not primarily lexically driven, though lexical similarities still account for many of the mutual sequences.

To investigate this further and disambiguate the relationship between form and content, the correlation (Pearson's and Spearman's) is calculated between the similarity ranks of the prosodic sequencing method and ranks of a traditional lexical method using lemmata unigrams (*r* .624 (rank .640)), bigrams (*r* .799 (rank .801)), and trigrams (*r* .834 (rank .839)). While these coefficients are high, the main concern are the nearest neighbors, a top 20 overlap of the two methods reveals a slightly different picture: unigrams (21.8%), bigrams (32.6%), and trigrams (36.2%). These results suggest that while form and content in MHG together contribute to what one may call ‘genre’, a large share of this grouping may be similarities in form derived from the prosodic sequencing features.

Which texts exhibit the most similar and most different rank similarities between the two methods? The top 20 overlap argues that the best-matched texts in form and content are Heinrich von Veldeke’s *Eneide*, Konrad von Würzburg’s *Herzmaere*, and Gottfried von Straßburg’s *Tristan*. Interestingly, most texts in the top 10 for being best-matched are those most studied by scholars historically, and are broadly considered founders of the genre. In contrast, the most mismatched texts in form and content are Konrad’s *Der Ritterspiegel*, *Die Klage der Kunst*, and the anonymous *Lohengrin* (none of the top 20 most similar texts measured by form are the same as the top 20 texts measured by content). Severe mismatch is often an intentional aesthetic strategy, made famous by Wolfram in *Willehalm* and *Titurel*, producing what Christoph März calls a “Verfremdungseffekt”, or defamiliarization effect, per Shklovsky (März, 1999: 327).

Abstract

This paper introduces the field of international textbook research and discusses how the WorldViews project is working towards enhanced access to textbook resources for digital humanities research.

Textbook Research

The field of textbook research is one of the more recent and more diverse areas of academic investigation. The condensed and canonical character of the information selected for inclusion in textbooks - here understood as conventional textbooks - gives them central significance in academic, political and educational respects. Textbooks, as carriers of the knowledge and information that one generation wishes to pass on to the next, frequently find themselves at the center of political controversy. As such, their importance as an object of investigation in historical and cultural research has gained significant traction in recent decades. However, textbook research has not yet found dedicated representation as a main subject at universities.

As a non-university institution, the Georg Eckert Institute (GEI) for International Textbook Research conducts and facilitates applied and multidisciplinary research into textbooks and educational media primarily informed by history and cultural studies. For this purpose, the GEI provides digital and social research infrastructure services such as its renowned research library and various dedicated digital information services, such as Edumeres, a virtual network with modules for specific aspects of textbook research. As such, the GEI realizes a unique position in the international field of textbook research.

The study of textbooks has not only been facilitated by growing institutional support and infrastructure but also by the proliferation of new digital methods and resources in humanities research. In the digital humanities, the investigation of research questions is supported by a range of increasingly sophisticated digital methods such as automatic image and text analysis, linguistic text annotation, or data visualization. Digital tools and services combined with the increasing amount of resources available through digital libraries (such as the German Digital Library, the Deutsches Textarchiv, and Europeana) and research infrastructures (such as CLARIN or DARIAH) provide digital support for textbook analysis.

Digital Information Services

At the GEI, the shift towards more digitally oriented research has resulted in a range of digital information services specifically tailored to textbook research. EurViews, for example, is a multilingual digital platform containing primary sources from twentieth and twenty-first century history textbooks from around the world that manifest particular concepts of Europe and Europeanness (for example, see Gehler and Vietta, 2010; Best et al, 2012, and Chakrabarty, 2000). The service also offers essays, commentaries, and educational histories written by designated experts in the field. EurViews is a useful tool for historians searching for relevant, reliable and hard-to-find research materials on topics related to textbooks. The materials may provide inspiration for research projects or be the starting point for more extensive searches for sources. EurViews also demonstrates that the printed monograph is no longer the dominant form of publication but that digital representation is gaining in importance.

Digital representations are increasingly becoming objects of investigation themselves. GEI-Digital , for example, a digital library focusing on out-of-copyright works published between the inception of textbooks in the seventeenth century and the demise of imperial Germany in 1918, holds potentially relevant textual resources for EurViews. Other important information services provided by the GEI offer factual and bibliographic data relevant for textbook research: edu.data, for example, provides information about textbook systems in individual countries, and the library catalogue contains bibliographic metadata about textbooks from around the globe.

While these services all contain resources and information that are immediately relevant to textbook research, their content is frequently stored in isolated data silos that lack appropriate interfaces or standardized data models and which prevent convenient use or exchange of data within the GEI or with external services. For example, even though GEI-Digital makes metadata about its resources available as METS/MODS encoded data via an OAI-PMH interface, EurViews lacks the interfaces that would enable it to utilize these full-text resources. Similarly, data on textbook systems from edu.data or bibliographic metadata from the library catalogue cannot be reused by existing or new research projects. External digital humanities infrastructures such as CLARIN-D are also unable to easily access texts stored in GEI-Digital or EurViews since those platforms contain plain text documents only which are not semantically annotated.

WorldViews

The WorldViews project, which is financed by the Federal Ministry of Education and Research (BMBF), addresses these challenges in order to further elevate access to textbook resources. Its aim being to enhance discoverability, reusability, and sustainability of textbook resources in cultural and historical research and in the digital humanities. The formative use case has been the digital platform for textbook sources, EurViews, a service that has proven to be in high demand– Since 2015 EurViews has had an average of 400 visitors per month, a comparatively high number for this kind of digital academic service– and which constitutes one of the cornerstones of the GEI's research infrastructure.

Two significant milestones have been achieved on the path to enhanced access. The first is the selection of the Text Encoding Initiative (TEI) standard that will be used to encode the semantics of conventional textbook resources and thus facilitate access to full-text sources. In addition, the Component MetaData Infrastructure (CMDI) framework has been chosen for the overall integration of metadata at the GEI; a framework also compatible with the CLARIN-D infrastructure.

An extensive search for publicly available and dedicated encoding schemas for textual characteristics of conventional textbooks yielded no results. Therefore, a profile specifying the most relevant metadata and textual features in textbooks was developed from scratch after consulting historians at the GEI. The only viable option for creating an encoding schema based on the profile turned out to be the TEI encoding standard. The TEI schema created for textbooks focuses on basic elements for the selective and formal description of those structural and semantic features that are immediately relevant for WorldViews. For example, headings of sections or the semantics of particular paragraphs should provide the necessary semantics to enable retrieval scenarios to contextualize search results and to formulate more precise queries targeting particular segments of the text. This ground-breaking schema is designed to provide the nucleus for more comprehensive descriptions of whole textbooks, such as those found in GEI-Digital.

The Component MetaData Infrastructure (CMDI) provides a framework that allows blueprints of distinct metadata components to be defined and reused. CMDI allows standard metadata components to act as profiles for virtually any kind of metadata. CMDI profiles have been created to describe textbooks resources in WorldViews (we have switched to the new version of CMDI, released in mid-2016) and we are currently investigating their application in more fact-based resources such as edu.data. By using CMDI as a general framework for metadata descriptions, full-text resources can immediately be indexed by CLARIN's Virtual Language Observatory and can be analyzed using its various tools and services such as Weblicht. The CMDI description of GEI resources allows for internally standardized search and retrieval operations in federated search scenarios.

The second milestone for better access to textbook resources was the implementation of a logic tier. Central components of this tier are Solr-indices for federated searches, tools for handling digitization workflows, controlled metadata annotation and full-text annotation of textbook sources and, significantly, a Fedora repository that will dynamically provide access to standardized representations of textbook resources and other data from the various digital infrastructure services at the GEI for internal as well as external consumers. After extensive evaluation of similar repository software such as DSpace, Fedora was selected due to the greater customizability and flexibility offered by its strong modularity and existing applications with CMDI metadata. Furthermore, use of Fedora is a prerequisite for becoming a CLARIN center, one of the long-term objectives of the GEI. Through the logic tier digital platforms such as EurViews are able to send queries for bibliographic metadata on newly added textbooks directly to the library catalogue or they can directly reuse textbook resources from other systems such as GEI Digital or obtain contextual data from databases such as edu.data.

Summary

The WorldViews project has four main strategies aimed at improving overall access to digital textbook resources through enhanced reusability, discoverability and sustainability. These are a logic tier based on the Fedora repository, which mediates data between internal and external services; the digitization workflow tool Goobi, which controls metadata descriptions of digitized textbook resources; full-text encoding schemas based on TEI; and the metadata standardization based on the CMDI framework. WorldViews has laid the groundwork for standardized data models at full-text and metadata level in the field of textbook research; thereby providing a firm foundation for textbook resources and related data to be made accessible for digital humanities research.

Word Vectors in the Eighteenth Century

Ryan James Heuser
heuser@stanford.edu
Stanford University, United States of America

Introduction

This talk explores how new vector-based approaches to computational semantics both afford new methods to digital humanities research, and raise interesting questions for eighteenth-century literary studies in particular. New semantic models known as “word embedding models” have generated excitement recently in the natural language processing and machine learning communities, due to their ability to represent and predict semantic relationships as complex as analogy. “Man” is to “woman” as “king” is to what?, one can ask of the model; “queen,” it will most likely reply. These models formulate analogical and other semantic relationships by computing mathematical vectors for words, such that, if *V(x)* denotes the vector for the word *x*, then the above analogy can be expressed as *V(woman) – V(man) + V(king) ≈ V(queen)*. Although these models have a longer history– vector space semantics dates from the ‘70s, having been first developed for the SMART information retrieval system (Salton, 1971) by Gerard Salton and his colleagues (Salton et al, 1975)” (Turney and Pantel, 2010)– new innovations in their speed and accuracy (see Note [1]) have renewed researchers’ interests—a development begun, in part, by Google, when researchers there unveiled newly efficient algorithms in 2013, packaged in software they released called word2vec. (The word2vec algorithm was originally described by Mikolov et al, 2013. It introduced the neural network to vector space semantics, providing an efficient means by which to compute word vectors. The GloVe algorithm from the Stanford NLP Group eschews the neural network approach, instead performing a novel method of dimensionality reduction on word collocation counts).

“Word vectors,” as these new methods are sometimes informally called, have already enabled published research into questions relevant to humanistic research, such as a recent landmark paper from researchers in the Stanford NLP Group into patterns of semantic change across centuries of discourse (Hamilton et al). However, unfortunately, word vectors have so far rarely appeared in research from the digital humanities community itself. Moreover, what work that does exist has so far been primarily circulated through blogs, rather than through published proceedings or articles. Ben Schmidt, for instance, has written an influential introduction to word vectors in his blog post “Vector Space Models for the Digital Humanities” (2015a), which also includes a documented R package for computing them. Also notable is his post, “Rejecting the gender binary” (Schmidt, 2015b), which uses word vectors to dissect the polysemy of words; as well as Michael Gavin’s post, “The Arithmetic of Concepts” (2015), which explores the conceptual implications of adding and subtracting word vectors.

On the whole, the current research landscape of word vectors in the digital humanities resembles the landscape of topic modeling years ago, when the original LDA algorithm (published in 2003 [Blei et al]), before appearing in landmark published DH studies such as Matt Jockers’ *Macroanalysis* (2013), was employed for humanistic research as early as 2006 by researchers working outside or tangentially to the digital humanities (Newman and Block).

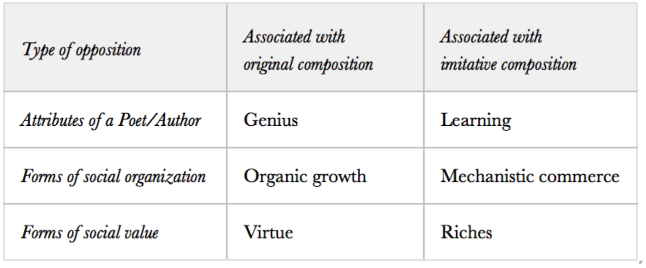
Given this scarcity of digital-humanities research on word vectors, work that seeks equally to explain, interpret, and demonstrate their potential seems particularly useful. With these goals in mind, this paper attempts first to unpack for a digital-humanities audience how word vectors work, with reference to the canonical analogy cited above: “man is to woman as king is to queen.” Second, in order to interpret word vectors’ conceptual implications for eighteenth-century literature, I move away from this canonical analogy to one central to a particularly influential argument in the period: “Learning is to Genius as Riches are to Virtue.” Lastly, I turn from this close reading of word vectors to methods of distant-reading analogies that lie implicit in eighteenth-century literature.

Explaining Word Vectors

How do word vectors work? In the interests of space, I have omitted this section of my talk from the abstract. Readers curious about the mechanics of word vectors can read more on my blog, which also links to a number of other explanatory resources (Heuser, “Methods”).

Close-reading Word Vectors

Word vectors provide a persuasive computational means for the semantic representation and analysis of analogies. They combine a mathematical elegance with an intuitive interpretability to yield what is, potentially, a method useful not only for large-scale semantic analysis, but also for smaller-scale explorations of particular analogies in literature, and their specific forms of analogical argumentation. For instance, analogy lies at the heart of Edward Young’s essay *Conjectures on Original Composition (1759),* which argued for the superior aesthetic interest of modern, “original” composition over the neoclassical imitation of the ancients. Crucially, Young makes his argument through analogy, identifying several other conceptual contrasts as analogues to his central one between original and imitative composition:

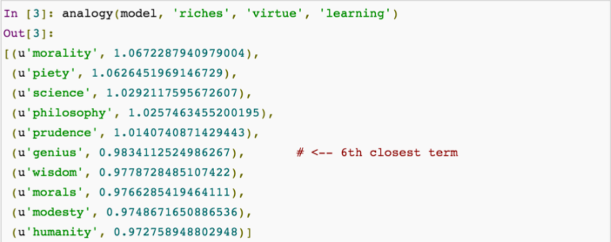


Type of opposition	*Associated with original composition*	*Associated with imitative composition*
Attributes of a Poet/Author	Genius	Learning
Forms of social organization	Organic growth	Mechanistic commerce
Forms of social value	Virtue	Riches

Table 1. Table of conceptual analogies leveraged by Edward Young to argue for original over imitative composition (Conjectures on Original Composition, 1759).

“I would compare Genius to Virtue, and Learning to Riches,” Young writes; “[a]s Riches are most wanted where there is least Virtue; so Learning where there is least Genius.” In this way, Young’s valuation of “Genius” over “Learning,” and of original over imitative composition, become *ethically justified* through their analogy with another, more obviously moral contrast between “Virtue” and “Riches.”

But what is the logic behind this analogy? Here, word vectors provide the close reader with a framework, language, and method of exploring the semantic implications at work in an analogy. In terms of vectors, we can ask, what does *V(Virtue)-V(Riches) (*Also sometimes expressed here, in a shorthand, as V(Virtue-Riches) mean, and is it in fact correlated with *V(Genius)-V(Learning)* in the broader discourse of the period? Asking this question of a word2vec model trained on the 80 million words of eighteenth-century literature in the ECCO-TCP corpus, we find that "Riches" are to "Virtue" as "Learning" is to...



```
In [3]: analogy(model, 'riches', 'virtue', 'learning')

```

Figure 1. "Riches" are to "Virtue" as "Learning" is to what?, asked of a word2vec model trained on 80 million words of eighteenth-century literature (the ECCO-TCP corpus).

"Genius" is the sixth closest word vector, or the sixth most likely solution, to this analogy. How to test the significance of this result is not immediately clear, but, out of tens of thousands of possibilities, it's certainly provocative: it raises the possibility that word vectors might provide computational assistance to close readings. Indeed, the other words in this list amplify the semantic profile of this analogy in a way that might help to clarify its underlying implications. For instance, the contrast between the *intrinsic* form of value in "Virtue" and the *extrinsic* form of value in "Riches" seems underscored for me by the contrast here between the extrinsic writerly attribute of "Learning," associated with an Oxbridge education, and the intrinsic attributes of morality, genius, and wisdom.

Ultimately, however, what does it mean to close-read word vectors? This is a question raised by Gabriel Recchia in a blogpost responding to my interpretation above as it first appeared on my blog (Recchia; Heuser, "Concepts"). Recchia's post explores other vector operations that even more reliably yield "genius," namely *V(learning)+V(virtue)* and *V(talents)+V(abilities)+V(erudition).* To me, however, these alternative "paths" to genius do not exclude one another; instead, each contributes to our understanding of the semantics of genius in the period. My goal with this interpretation is not to "prove" Young's analogy, but rather to suggest that, by "amplifying" a particular analogy through its semantic associations across a corpus, word vectors help contextualize our interpretations of particular analogies in literature. As Recchia writes, "the computational exercise has helped us focus our search."

Distant-reading Word Vectors

If, then, vectors help us explore this *micro*-analytic scale of interpretation, they also help us scale those same interpretive models up to the level of macroanalysis. For instance, inspired by the foregoing close-reading of Young's complex web of analogies (Table 1), we might continue Young's project of obsessive analogization by way of a distant reading. By defining vectors for a range of common eighteenth-century contrasts (Table 2), and then measuring the correlation between them, we can in fact construct *another* complex web of analogies—this time gleaned computationally, from a large-scale archive of the period's discourse.

Ancient(s) <> Modern(s)	Private <> Public
Beautiful <> Sublime	Romances <> Novels
Body <> Mind	Ruin <> Reputation
Comedy <> Tragedy	Simplicity <> Refinement
Folly <> Wisdom	Tradition <> Revolution
Genius <> Learning	Tyranny <> Liberty
Human <> Divine	Virtue <> Honour
Judgment <> Invention	Virtue <> Riches
Law <> Liberty	Virtue <> Vice
Marvellous <> Common	Whig <> Tory
Parliament <> King	Woman <> Man
Passion <> Reason	

Table 2: Common eighteenth-century contrasts, each expressed as a vector contrast. For instance, Virtue <> Vice denotes the vector V(Vice-Virtue). Contrasts were gleaned manually while reading Fielding's Tom Jones (1748), as well as a number of essays from the period; they are not meant to be exhaustive. This is an admittedly unsatisfactory method; I am currently exploring ways to discover conceptual contrasts computationally.

Looking at a particularly strong correlation among the contrasts in Table 2, between *V(Simplicity-Refinement)* and *V(Virtue-Vice),* we can see how their correlation emerges from the way in which both contrasts carry similar semantic associations across the same set of words (Figure 3).

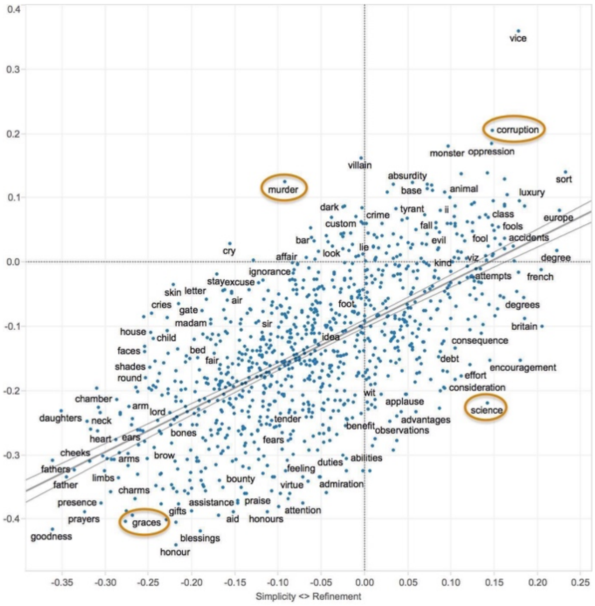

Figure 2. 1,000 most frequent nouns in the ECCO-TCP corpus. On the x-axis is their cosine similarity with the V(Simplicity-Refinement) vector: if above 0, then associated more with refinement; if below, more with simplicity. Conversely, on the y-

axis, above 0 means associated more with Vice; below 0, more with Virtue.

In other words, this graph shows that there are more words for simple virtues (e.g. "graces") than refined virtues (e.g. "science"), and more words for refined vices (e.g. "corruption") than simple vices (e.g. "murder"). This correlation between their semantic associations (R^2 = 0.41) reveals, then, an analogy emerging from the period's broader discursive practices—Simplicity is to Refinement as Virtue is to Vice—even as that analogy might appear only implicitly in particular essays, such as in Hume's "Of Simplicity and Refinement in Writing" (1742), when Hume loosely associates refinement with the moral decline of post-Augustan Rome.

This macro-analytic approach to discovering implicit discursive analogies allows us to visualize the ways in which the frequent conceptual contrasts in eighteenth-century literature are implicitly analogized in the discourse, and how those implicit analogical relationships may have helped to structure what Peter De Bolla has called the "conceptual architecture" of the period (Figure 4).

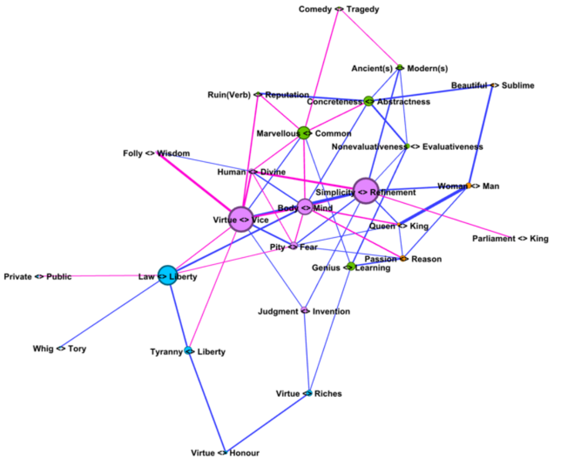

Figure 3. Semantic contrasts are connected in this network if the R^2 value of their correlation, across the 1,000 most frequent nouns (as in Figure 3), is greater than 0.1. Blue lines read in the natural order (e.g. Simplicity is to Refinement as Woman is to Man); red lines read in reverse order (e.g. Simplicity is to Refinement as the King is to Parliament). Nodes are sized by betweenness centrality, and colored by network community. Edges are sized by the R^2 value.

From this network of correlated contrasts, we can see which of them, for instance, are implicitly gendered in the period's discourse. "Woman" is to "man," for instance, as "queen" is to "king"—but also as the beautiful is to the sublime, as simplicity is to refinement, and as passion is to reason. Similarly, we can see which contrasts are moralized in the period: "virtue" is to "vice" as wisdom is to folly, as pity is to fear, as the mind is to the body. Moreover, the contrasts of virtue and vice, and simplicity and refinement, might actually play a central role in such a conceptual architecture of analogies, as seen from their centrality within the network.

Conclusion

I hope to have demonstrated some of the ways in which word vectors might be useful for the digital humanities, and particularly for eighteenth-century literary studies, both by demonstrating how they might help us to close-read specific analogical maneuvers, as well as distant-read analogies as they emerge from patterns in their usage across a literary discourse.

Notes

[1] According to statistics provided in the original paper for the Stanford NLP group's "GloVe," a competing algorithm to word2vec, a word2vec model trained on a large English-language corpus can accurately solve 65% of analogies in a test dataset, and GloVe 75% (Pennington et al, Table 2). As a rough comparison to the accuracy we would expect from human subjects, we might look to the Miller Analogy Test from Pearson—an admittedly unrelated analogy test, which is given to some graduate student applicants. In the MAT of 2002-3, to accurately solve 65% or more of its 100 analogies places a student above the 80th percentile (Pearson). Although not directly comparable, these statistics make more probable the assessment that word vectors are capable of capturing semantic relationships at a level competitive with human subjects.

In Defense of Sandcastles: Research Thinking through Visualization in DH

Uta Hinrichs

University of St Andrews, United Kingdom

Stefania Forlini
sforlini@ucalgary.ca
University of Calgary, Canada

Introduction

Although recent research acknowledges the potential of visualization methods in DH, the predominant terminology used to describe visualizations (prototypes, tools) narrowly focuses on their use as a means to an end and, more importantly, as an instrument in the service of humanities research. While acknowledging the broad range of possible approaches to visualization, we introduce the metaphor of the sandcastle to highlight visualization as a research process in its own right. We argue that building **visualization sandcastles** provides a holistic approach to interdisciplinary knowledge generation that embraces visualization as (1) a dynamic interdisciplinary process where speculation and re-interpretation advance knowledge in all disciplines involved, (2) a mediator of ideas and theories within and across disciplines and (3) an aesthetic provocation to elicit critical insights, interpretation, speculation and discussions within and beyond scholarly audiences. We illustrate our argument based on our own research of an exceptional literary collection.

Visualization tools vs. sandcastles

Pivotal Scene

A steering committee meeting for a large-scale DH project. The goal of this interdisciplinary project is a combined computational and literary analysis of a literary collection, which will include the development of visualizations to enable the open-ended exploration of this collection by literary scholars. As the discussion starts to focus on the intended project outcomes, questions around the visualizations and their practical and research contributions arise. What role do visualizations play as part of DH projects? What makes them a valid contribution? One committee member brings it to the point: "Are we building **tools** or **just sandcastles**?"

This question contrasts **sandcastles**—tailored, unique, often stunning yet also transient and unstable interactive visualizations—with more pragmatic, functional and transferable visualization **tools.** This framing is a provocation: these approaches are not necessarily diametrically opposed or mutually exclusive, but, rather, exist along a rich continuum. Even within one research project, the process can shift from a more transient 'sandcastle' to a more targeted instrumental approach. And yet, the preference toward the latter is evident in recent DH discussions (Gibbs et al., 2012) and in a push by funding bodies toward research with concrete, high-impact outcomes. Notably, however, visualization 'tools or prototypes' (terms typically used interchangeably) are not usually seen as research contributions in their own right (Schreibman et al., 2010) but, at best, as facilitators of research or as a way to communicate underlying research contributions. An overly pragmatic approach to visualization, and DH tool-building more generally, however, not only risks overlooking the value of the design process but also relegating computer science and design to service-based roles. What happens when we consider, as Bruno Latour has argued, that "far from fulfilling any purpose", a new technology actually "explor[es] heterogeneous universes that nothing, up to that point, could have foreseen and behind which trail new functions" (Latour, 2002: 250)? What happens when we attend to the design process—and its many detours—as a research process in and of itself?

As a relatively young research field, information visualization (InfoVis) has seen calls to carefully and critically (re-)evaluate sometimes dated assumptions (see Kosara, 2016). Similarly, despite the increasing application of visualization in diverse DH contexts (Jänicke et al., 2015), it remains a relatively new approach and a call for generalizable visualization tools—drawing on science-based use cases—may reproduce unexamined assumptions and overlook important nuances of humanistic data and inquiry that is typically of a qualitative and interpretative nature (Drucker, 2011). As Latour argues, the ways in which we represent our arguments changes the way in which we argue (Latour, 1986). Introducing visualization into literary studies, introduces new modes of knowledge production. As such, we need to engage in open-minded and open-ended explorations of visualization as a research (rather than engineering) process, paying close attention to the ways this process changes our perspectives on data and research questions. At a time when leading practitioner-theorists suggest design as central to DH (Burdick et al., 2012), we must develop a more nuanced, critical language to discuss and further engage with the wide range of design approaches, especially from fields such as InfoVis and human computer interaction (HCI) that already combine design practice and research.

The call for a broader perspective on technology design within DH is not new, but it is increasingly urgent as the pragmatic value of visualization tools risks overshadowing the profoundly fertile design process as an intellectual and cognitive practice or a "method of thinking-through-practice" (Burdick et al., 2012). Previous work has discussed "tools" in DH as "experiments" or "embodiments of ideas" (Sinclair et al., 2011), advocated for prototypes as arguments in their own right (Galey & Ruecker, 2010), and highlighted visualization as a starting point to humanities research rather than a means to an end (Hinrichs et al., 2015; Forlini et al., 2015b; Hinrichs et al., 2016). Furthermore, critical perspectives from within the DH (Drucker, 2011) and InfoVis communities (Dörk et al., 2013; Hullman & Diakopoulos, 2011) call for further examinations of the rhetoric of visualizations. Expanding on these discussions, we reclaim the 'sandcastle' as a lens through which to critically examine current DH discussions of technology design and to promote an open-ended, speculative and process-oriented approach to visualization design based on a robust model of interdisciplinary collaboration that advances knowledge in all research fields involved. Our argument is grounded in critical theory, design research, HCI and InfoVis, as well as in our own experience of combining research in literary studies and visualization to explore an untapped collection—the Gibson Anthologies of Speculative Fiction (Forlini et al., 2015b; Hinrichs et al., 2015).

Building sandcastles at the intersection of literary studies and InfoVis

Our project—the Stuff of Science Fiction—explores a vast untapped collection of 10,000+ science fiction stories single-handedly compiled into 888 hand-crafted anthologies by the avid science fiction fan, artist and collector Bob Gibson (see Fig.1). This unusual collection raises a number of questions regarding the evolution of science fiction in the context of popular periodicals and the role of fan practices in sustaining and promoting this popular genre. Working with a subcollection of 1,500+ stories, we developed interactive visualizations that came together as the Speculative W@nderverse (see Fig. 2) to help us explore and analyze these stories through their metadata.

The W@nderverse can be considered a tool, or at least a prototype, and we have discussed it as such in our own humanities (Forlini et al., 2015a; Forlini et al., 2015b) and InfoVis publications (Hinrichs et al., 2016). In many ways it is a means to certain valuable ends: (1) it makes the Gibson anthologies explorable from different (visual) perspectives by multiple scholarly and public audiences, (2) it has generated insights about the collection, and (3) it showcases InfoVis design considerations specific to visualizing untapped literary collections (Hinrichs et al., 2016).

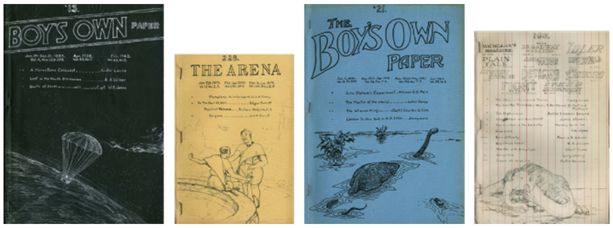

Figure 1. The Gibson Anthologies of Speculative Fiction

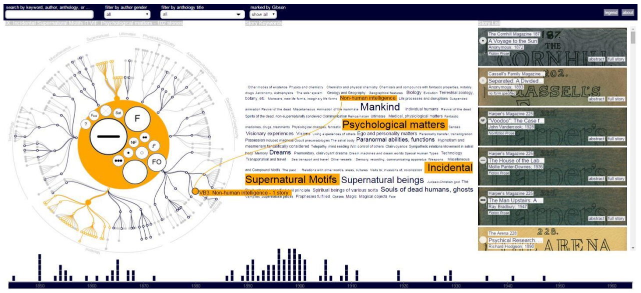

Figure 2. The Speculative W@nderverse visualization

However, if we reflect on our process with our initial research questions on one end and the visualization as a reflection of our research outcomes on the other, it becomes clear that the W@nderverse is not just a tool, at least not in the narrowly instrumental sense. It only appears to be a means to certain ends **in retrospect** when we overlook our many detours in order to narrate (for the sake of dissemination) a direct line from our questions to our contributions. However, our grant proposal and the copious notes through which we documented our research process (see Neustaedter & Sengers, 2012) remind us of our initial intentions and reveal the transformative nature of our collaborative "prototyping" process, which profoundly altered our research questions and intentions as well as our perspectives on the collection and our respective disciplines—literary studies and InfoVis. The W@nderverse is therefore both the mediator and manifestation of our exploratory and interdisciplinary research process. Our many design detours (necessitated by ongoing archival discoveries and visualization experiments, see Fig. 3), show what is now largely invisible yet fundamental to the W@nderverse: our **research thinking through visualization**, an approach that has its parallel in HCI with "research through design" (Zimmerman, 2007).

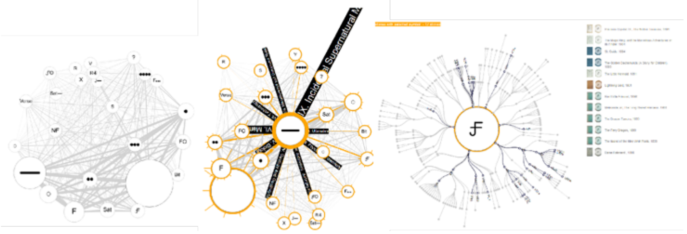

Figure 3: Early visual speculations leading up to the W@nderverse

In order to investigate humanities questions from truly novel perspectives and to engage in profoundly interdisciplinary collaborations that combine humanities and visualization research (not engineering!) approaches, we advocate for research thinking through the creation of visualization sandcastles as:

- Aesthetic and in-flux **manifestations of visualization as a speculative, provocative process** that generates insights about: 1-the underlying collection; 2-(visualization) design considerations; 3-needs of the intended audience(s); 4-and new research questions which, in turn, drive the development of new (and different) sandcastles and grounded insights valuable to all involved disciplines,
- **Dynamic mediators** that by provoking and guiding discussions can bridge boundaries between disciplines (e.g., literary studies & InfoVis) and between academic and fan endeavors, and
- **Aesthetic provocations** that can promote critical discussions of best practices for studying and making accessible cultural collections among scholarly and public audiences.

Beyond Validation: using programmed diagnostics to learn about, monitor, and successfully complete your DH project

Schema-based validation of XML documents has long been a fundamental tool for quality control in digital edition projects, and the emergence of richer schema languages and adjuncts such as Schematron has greatly improved the constraints and controls available to XML authors and encoders (Jacinto et al. 2002). However, schema-based validation typically takes place at the document level, whereas "most programs that use XML require information that is not encoded in the XML instance or in the schema that governs it" (Vorthmann & Robie 2001). The modern digital edition project typically consists of multiple documents with large numbers of pointers between them: links between named entities and personographies, placeographies and bibliographies; pointers to external documents and fragments, images and other media; and similar complex interrelationships within the collection, and to external resources and authorities. These relationships need to be tested, checked, and validated too, but it is impractical to do this using document-level schemas. As Durand et al. (2009) point out, "such testing requirements are in fact closer to conventional system or software testing requirements than to document testing in a narrow sense." Most large- and medium-scale projects develop their own methods, programmed and/or impromptu, for addressing these problems, and these have been quite well-described and documented for enterprise-level and corporate contexts (for instance, see the papers presented presented at the International Symposium on Quality Assurance and Quality Control in XML, particularly Waldt 2012), but little has been published on project-level diagnostic testing for XML-based digital edition collections (see Rahtz, 2007)

In our work as part of Endings, an umbrella project that comprises four diverse digital edition projects from different fields, we have been developing a structured approach to implementing methods for checking and enforcing project correctness, consistency, and coherence, which we will describe in this paper. Influenced no doubt by Star Trek, we have long referred to these processes as "diagnostics", and in our description we follow the franchise tradition detailed in Sternbach and Okuda (1991) in dividing diagnostics into levels; however, we depart from convention in ordering our levels from most granular/least comprehensive up to the most general. For each level, we provide real examples of processes run on one of our projects.

We stress that these diagnostics are built on top of a solid basis of RelaxNG and Schematron schemas. In the case of our projects, we use highly-customized versions of the TEI schema (all TEI-compliant) in addition to project-specific Schematron rules, which not only police tagging practices (e.g. enforcing the use of private URI schemes in pointing attributes, and checking the presence of appropriate custom dating attributes for pre-Gregorian dates), but also style guide rules such as prohibiting the use of straight apostrophes in document text nodes (excepting computer code samples). Our diagnostic processes normally take the form of ant scripts and XSLT transformations, and are run on a Jenkins Continuous Integration server; every time changes are committed to a project repository, the Jenkins server checks out the changes, validates all documents, and runs the entire set of diagnostics processes, providing the results in the form of a public web page such as this one:

Figure 1: A diagnostics output page from the Map of Early Modern London project.

In combination with this paper, which is intended to be a useful primer and guide, we have developed a Diagnostics project hosted on GitHub. that can be used by researchers whose digital edition projects have grown to the point where ad hoc manual checking has become impractical. This tool provides generic referential integrity checking that can be applied to any set of TEI XML files.

Level 1

Level 1 diagnostics provide project-level, as opposed to document-level, consistency checking to establish the internal coherence of the project, primarily through ensuring referential integrity. We borrow the phrase "referential integrity" from the MLA's "Guiding Questions for Vetters of Scholarly Editions" (2011), which advises peer-reviewers of digital editions that link to multiple databases to see if "referential integrity [is] enforced within the database(s)." This includes checking for non-existent pointers, duplicate @xml:ids across the project, and erroneously encoded references (e.g. tagging a place name as a bibliography reference). Ensuring referential integrity is particularly complex for projects that use "abbreviated pointers" to facilitate internal linking (see TEI Consortium (2016)), since it may not be obvious to the encoder which resource is being referenced by a pointer. Thus, the first level of diagnostics checks both whether or not an object pointed to actually exists and whether or not the markup correctly represents the relationship between the element and the target resource. For instance, to check all instances of the relationship shown in Fig. 2, a number of different tests are actually done:

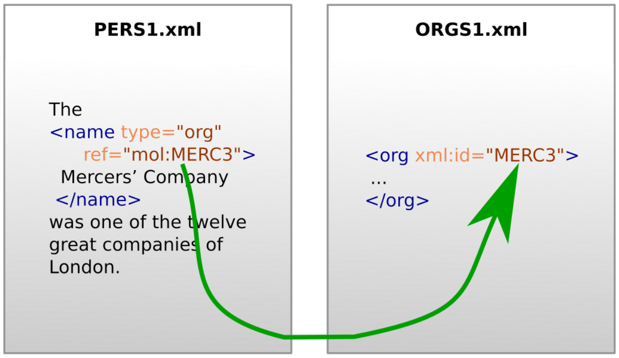

Figure 2: a simple referential integrity check.

1. Every <name type="org"> points at an @xml:id which exists in the project.
2. The element pointed at by <name type="org"> is an <org> element in the ORGS1.xml document.
3. Every <name> element which points at an <org> element in ORGS1.xml has @type="org".

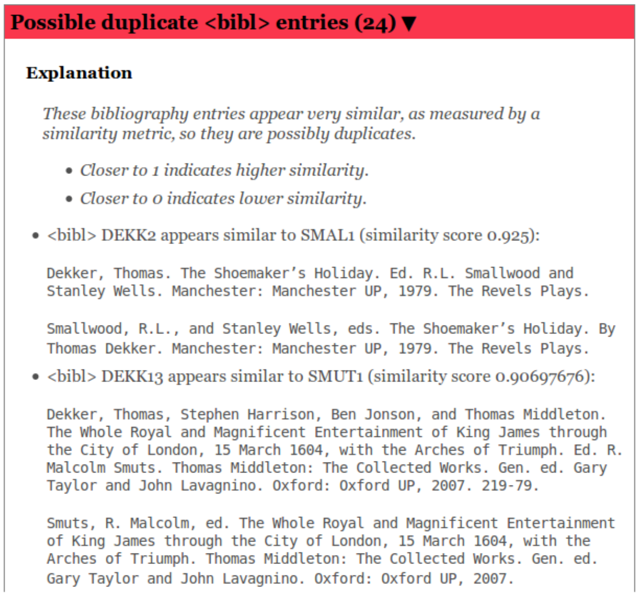
For small-scale projects, this kind of referential integrity check could be accomplished with Schematron, since a Schematron rule using XPath 2.0 can read external documents, but for a project of any significant size, this is impractical. For example, Schematron checks to confirm the rules above may add around six seconds to document validation in the Oxygen XML Editor, causing frustration for editors, while simply checking that a linked location exists would require the processing of over a thousand files in this project, since each location is a distinct file.

Level 2

While Level 1 diagnostics generally focus on coherence and consistency, Level 2 is more concerned with completeness. Level 2 diagnostics provide progress analysis, generate to-do lists, and identify situations that may indicate error, but require human judgement. These include cases in which:

- Two bibliography or personography entries appear sufficiently similar that they may be duplicates.
- Several <name> elements point to the same authority record, but the text of one of them is significantly different from the others, so it may point at the wrong target.
- A document in the project is not linked from anywhere else, and therefore cannot be "reached".

Such issues cannot be automatically rectified—they are not necessarily errors—but they must be examined. Figure 3 shows an example of the first check, which uses a similarity metric to identify potential duplicate bibliography entries.



Possible duplicate <bibl> entries (24) ▼

Explanation

These bibliography entries appear very similar, as measured by a similarity metric, so they are possibly duplicates.

- *Closer to 1 indicates higher similarity.*
- *Closer to 0 indicates lower similarity.*

- <bibl> DEKK2 appears similar to SMAL1 (similarity score 0.925):

```
Dekker, Thomas. The Shoemaker's Holiday. Ed. R.L. Smallwood and
Stanley Wells. Manchester: Manchester UP, 1979. The Revels Plays.

Smallwood, R.L., and Stanley Wells, eds. The Shoemaker's Holiday. By
Thomas Dekker. Manchester: Manchester UP, 1979. The Revels Plays.
```

- <bibl> DEKK13 appears similar to SMUT1 (similarity score 0.90697676):

```
Dekker, Thomas, Stephen Harrison, Ben Jonson, and Thomas Middleton.
The Whole Royal and Magnificent Entertainment of King James through
the City of London, 15 March 1604, with the Arches of Triumph. Ed. R.
Malcolm Smuts. Thomas Middleton: The Collected Works. Gen. ed. Gary
Taylor and John Lavagnino. Oxford: Oxford UP, 2007. 219-79.

Smuts, R. Malcolm, ed. The Whole Royal and Magnificent Entertainment
of King James through the City of London, 15 March 1604, with the
Arches of Triumph. Thomas Middleton: The Collected Works. Gen. ed.
Gary Taylor and John Lavagnino. Oxford: Oxford UP, 2007.
```

Figure 3: Results of a Level 2 diagnostic check that attempts to identify duplicate bibliography entries.

At Level 2, we also generate to-do lists for specific sub-projects, providing a set of tasks for the project team to focus on in order to reach a milestone or publish a particular document. The definition of "done" for a specific document may transcend the document itself. For instance, before we deem a particular edition of a text publishable, we may require that all authority records (people, places, publications) linked from that document are themselves complete, so the to-do list for a given document may require work in a variety of other documents in the project

Level 3

Armed with a comprehensive set of Level 1 and Level 2 diagnostics, and assuming our data is managed using a version-control repository such as Subversion or Git, we can now generate diachronic views of the project's progress. A script can check out a sequence of incarnations of the project, weekly over a period of months, for instance, and run the entire current diagnostic suite against it; we can then combine these snapshots to get a clear sense of how our work is proceeding. This also means that every time we develop a new diagnostic procedure, we can apply it to the entire history of the project to see the trajectory of project work with respect to the datapoint in question. Two examples, this time from the Nxaʔamxcín Dictionary project (an indigenous dictionary project described in detail in Czaykowska-Higgins, Holmes, and Kell (2014)) appear in Figs 4 and 5 below. Figure 4 shows the number of completed dictionary entries in orange, rising steadily over a period of 18 months, and the number of occurrences of a known problem: duplicate instances of the same gloss. These duplicates rise along with the number of entries until October 2016, when this issue was added to our diagnostics process, and the encoders were able to address it.

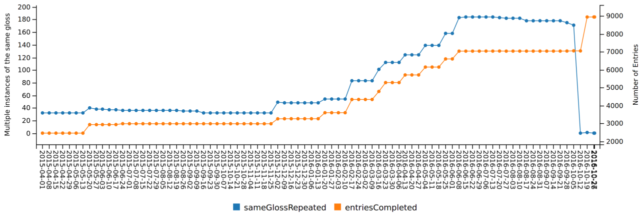


Figure 4: The number of instances of duplicate glosses, tracked against completed entries, in the Nxaʔamxcín Dictionary project.

Fig. 5 shows cases of broken cross-references, which also tend to increase along with the number of completed entries, but we can see from the graph that the issue was aggressively addressed in two separate campaigns in fall 2015 and summer 2016. New instances continue to appear, however.

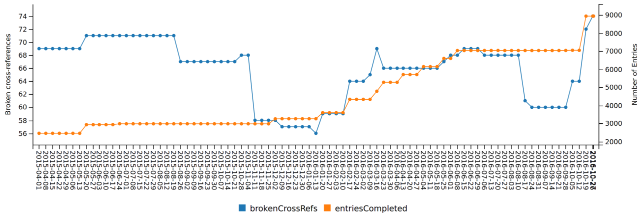

Figure 5: The number of broken cross-references, tracked against completed entries.

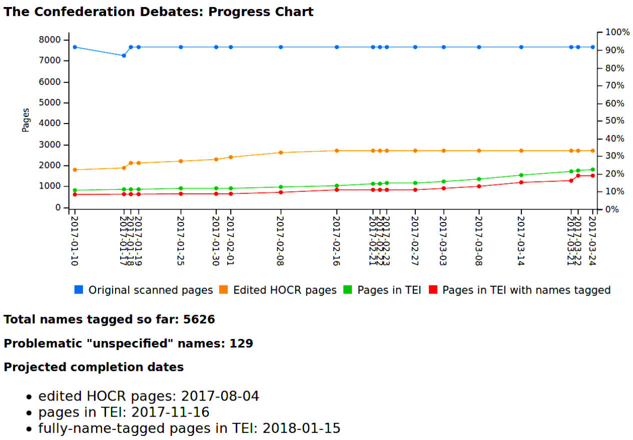
Fig. 6, from a different project, shows how this approach can be used to forecast completion dates for tasks in a project based on the progress rate so far.



Total names tagged so far: 5626

Problematic "unspecified" names: 129

Projected completion dates

- edited HOCR pages: 2017-08-04
- pages in TEI: 2017-11-16
- fully-name-tagged pages in TEI: 2018-01-15

Figure 6: Diachronic diagnostics used to project task completion dates.

Conclusion

As Matthew Kirschenbaum (2009) tells us, there “is no more satisfying sequence of characters” than “Done.” The overall purpose of a digital edition project is to finish and publish the edition, and this requires not only that the document-level encoding be valid, but also that the entire dataset be coherent, consistent, and complete. Programmed diagnostics enable projects to enforce coherence and consistency, manage the workflow effectively, and measure their progress towards completeness.

Transcriptional Implicature: Using a Transcript to Reason about an Exemplar

Claus Huitfeldt
Claus.Huitfeldt@uib.no
University of Bergen, Norway

C. M. Sperberg-McQueen
cmsmcq@acm.org
Black Mesa Technologies LLC
United States of America

What do transcripts tell us about their exemplars, and how? A transcript T is commonly said (inter alia) to reproduce as far as possible the letters and words of its exemplar E. The tokens of T typically reinstantiate the letter and word types of E; T may also contain commentary on E.

Transcribers vary in their practice: some record page and line breaks in E, silently omit deletions, expand abbreviations, and correct spelling; others don't. Often a statement of practice documents such details, but some things apparently go without saying. We conjecture that what goes without saying will be the most common assumptions and habits in a community of practice. We have proposed the term "transcriptional implicature" to denote the inferences licensed by a transcript although not explicitly justified in the statement of practice [SMMH2014].

Practice (and implicature) vary across communities, but we think that some silent assumptions are shared by almost every community of practice. We believe that we can identify a common core of such assumptions, and that individual practices can be characterized by listing their deviations from this core, which we call the "default rules" of transcriptional implicature.

Like all implicatures, the rules of transcriptional implicature are defeasible: they are taken to hold in the absence of evidence to the contrary. [SMMH 2014] proposes these rules:

- Reciprocity: There is a one-to-one relation between normal tokens in an exemplar E and normal tokens in its transcript T.
- Purity: Every normal token in T transcribes something in E.
- Completeness: Every normal token in E is transcribed by something in T.
- Type similarity: corresponding tokens in E and T have the same type, or non-identical but similar types.

Given these rules, the transcription practice of any project can be described by defining what counts for that project as a special (not "normal") token and what type pairs count as similar. This paper puts these general principles to an empirical test by applying them to a concrete example: the transcript, in the Northwestern-Newberry Edition, of Hermann Melville's notes on the end-papers of a volume of Shakespeare [Melville, p 967-970]

The "Symbols used" are (numbers ours):

1. [...] revision or insertion enclosed in square brackets was made later than initial inscription of leaf
2. <...> letters or words enclosed in diamond brackets were canceled by lining out
3. <...>word letter(s) or word(s) written over are enclosed in diamond brackets closed up to the following word or letter that was superimposed
4. ?word prefixed question mark indicates conjectural reading 5 xxxx undeciphered letters (number of x's approximates numbers of letters involved)
5. all words in roman are Melville's
6. all words in italics outside brackets are words Melville underlined
7. all words in italics inside brackets are editorial

If transcriptional implicature is to play the role we ascribe to it, it must be possible to recast these rules in terms of normal tokens, special tokens, and types instantiated by tokens:

- Square brackets, diamond brackets, question marks prefixed to words, and sequences of the form xxxx in T are special tokens; they transcribe no material in E.
- Italic material inside brackets in T is special.
- A word written without underlining and the same word underlined have distinct types in E; the same holds for italic and roman material in T. Words underlined in T and the same words italicized in E are type-similar.

- Later additions to E have distinctive types; that is, we can distinguish them. A sequence of words inserted in E and the same sequence enclosed in square brackets in T are type-similar.
- Overlined words, overwritten words, and words neither overwritten nor overlined instantiate different types. Overlined or overwritten word-types are instantiated in T by enclosing the words in diamond brackets.
- "Undeciphered letter sequences of length N" are distinct types for distinct N, instantiated in E by undeciphered characters and in T by sequences of the form xxxx. The individual x tokens are special: they do not transcribe tokens of E.
- A word prefixed with a question mark and the same word without it instantiate different types in T. Such a word token, and its constituent character tokens, are type-identical with their exemplars in E if the editors' conjectural reading is correct. We describe such tokens in T as "probably type-identical" to their exemplars.

Both generic and project-specific rules can be formalized using first-order logic. The generic rules include the rules of transcriptional implicature:

```
(∀t t:tokens(T))(normal-transcript-token(t) ⍰
      (∃1e e:tokens(E))(e = exemplar(t))

(∀e e:tokens(E))(normal-exemplar-token(e) ⍰
      (∃1t t:tokens(T))(t = transcript(e)))

(∀e e:tokens(E), t: tokens(T))(t = transcript(e) ⍰
      (type(e) = type(t) v type-similar(e, t))
```

Reciprocity has no formalization here; it's a property of the functions exemplar() and transcript().

Other generic rules constrain the classes of normal and special tokens:

```
(∀t t:tokens(T))(normal-transcript-token(t) |
      special-transcript-token(t))

(∀e e:tokens(E))(normal-exemplar-token(e) |
      special-exemplar-token(e))
```

The Melville-specific rules identify special tokens in T:

```
(∀t t:tokens(T))(special-transcript-token(t) ⍰
      (square-bracket(t)
      v angle-bracket(t)
      v prefixed-question-mark(t)
      v xxx-sequence(t)
      v (italic(t) & within-square-brackets(t))
      v (italic(t) & within-angle-brackets(t))
      v prefixed-question-mark(t)
      v page-furniture-token(t)))
```

The predicate page-furniture-token identifies material like running heads and page numbers in T. Project-specific type similarity rules cover conjectural readings:

```
(∀t t:tokens(T))(∀e e:tokens(E))
      (probably-identical(type(t), type(e)) ⍰
      type-similar(e, t))
```

The Melville transcription policy defines no special exemplar tokens:

```
¬(∃t t:tokens(E))(special-exemplar-token(t))
```

We hypothesize that it is rules like those above that enable readers of a transcript to draw conclusions about an exemplar they have never seen. Such reasoning can be formalized with the aid of a full formal representation of T and its mapping of tokens to types. In the case of Melville's notes, such a formalization will involve several thousand tokens in T and E and their types. The formal representation will not be given in full here, but it will include formulae like the following, in which "d", "p524", "L1", etc. are logical constants naming tokens:

```
document(d)
page(p524)
page(p525)
document_pages(d, (p524, p525)).
line_token(L1)
line_word_tokens(L1, (L1w1, L1w2, L1w3, L1w4, L1w5, L1w6, L1w7))
word_token(L1w1)
word_token(L1w2)
...
word_token_type(L1w1, "A")
word_token_type(L1w2, "seaman")
...
word_token_type(L1w7, "Tales.")
line_token(L2)
...
line_token(L40)
line_type(LT1)
line_type(LT2)
...
line_type(LT40)
page_lines(p524, (L1, L2, L3, ... L30))
page_lines(p525, (L31, L32, L33, ... L40))
```

Sequences are here represented using comma-separated lists of items, enclosed in parentheses.

As an example: We can infer from the transcript that the first line of the first page transcribed reads "A seaman figures in the Canterbury Tales." This will surprise no one who can read and understands what a transcript is. The challenge here, however, is to establish the result using nothing but the normal rules of logical inference, without hand-waving.

Let us focus on the line token L1. We draw our initial inferences from the formal representation of T. As is usual for composite types, the type of the line is determined by the types of the words which make up the line. So the type of L1 is the sequence of words (or characters) "A seaman figures in the Canterbury Tales."

```
composite_type_string(LT1, "A seaman figures in the Canterbury Tales.")
```

Since L1 is not a square bracket, diamond bracket, etc., it can be inferred that L1 is a normal not a special token. From the rule of purity it then follows that there is some token e in E which L1 transcribes. This fact, together with the rule of type-similarity, tells us that e is a token which like L1 instantiates the composite type "A seaman figures in the Canterbury Tales."

A second example: A student examining a reproduction of the original of Melville's notes might ask "Are the dots to the left of the first line significant, or just discolorations of the paper?" We take this question to mean "Do the dots instantiate a type?" Let us assume that they do. If they instantiate a type, then they are tokens in E; if they are tokens in E, then either they are normal or special. They cannot be special tokens: there are none in this transcription practice. If they are normal tokens, then there exists a token in T which instantiates the same type. But there are no such tokens in T. If there is no token in T which transcribes the dots at the upper left of the page, then they are not (in the transcribers' reading of E) normal tokens. If they are neither normal tokens nor special tokens, they are not tokens at all. So: they are merely marks, not tokens, and they instantiate no type.

We have postulated transcriptional implicature as a way of bridging the gap between the explicit statements in descriptions of transcription practice and the inferences actually licensed; the empirical test reported suggests that the concept does provide the required basis for the intended inferences. If formal representations of the information content of a transcript can be generated automatically (e.g. from a TEI-encoded transcript), then we will be slightly closer to being able to describe formally the semantics of transcription-oriented markup languages like MECS-WIT or TEI when used to transcribe pre-existing exemplars.

Pelagios Commons (Pelagios Commons 2017) is a community of practice dedicated to supporting Linked Open Data-related activity within the humanities. Comprising a series of interconnected Special Interest Groups, it operates through the collective establishment of digital conventions for semantic data and produces software to facilitate its production and use. Such data can ultimately be used to interconnect independently maintained and heterogeneous online resources about the past. While Pelagios Commons is engaged in a variety of activities to achieve these ends, this paper focuses on the development of a second generation implementation of its most popular tool, Recogito (Simon et al., 2015). Recogito is a semantic annotation system (Andrews et al., 2012) with similarities in some regards to platforms such as Pundit (Grassi et al., 2012) and Hypothesis (Hypothesis, 2017), but with particular focus on geographic content, and accessibility to humanists without high levels of technical literacy.

Recogito's origins lie in the earlier *Pelagios 3* project cycle dedicated to the semantic annotation of early geographic documents so as to provide a 'critical mass' of content to which other historical materials could be related. The intended goal was to identify place references, and their referents, in as many pre-1500 geographic documents as possible. Such documents, or more specifically their digital surrogates, could take a wide variety of different formats, but are typically represented as texts, images and tables. While the first phases of Pelagios saw annotation carried out by a community of resource curators, much - though not all - of the annotation for Pelagios 3 was conducted within the Investigative Team. As most of the documents to be annotated had no formal structure, it was necessary to develop a tool which allowed us to rapidly produce annotation records (recording a reference, a global gazetteer entry and an annotator). The result was *Recogito*, a web-based platform which allowed its users to upload digital surrogates and produce annotations pointing back to the original digital version of an online document.

The first version of Recogito offered multiple interfaces for the discrete tasks of: identifying place references (whether in text, image or table); transcribing them where necessary; relating them to an entry in one of multiple possible gazetteers (depending on the period of the document in question). Semi-automated processes based on Natural Language Processing and Named Entity Extraction techniques allowed the software to accelerate these tasks, while ultimately requiring all annotations to be verified by a human individual. Semantic interpretation is always underdetermined by a text or symbol, and thus human intervention remains a fundamental principle of the Pelagios methodology. While document surrogates were kept behind a log-in interface to prevent the possibility of copyright infringement, the annotations themselves were made publicly available in real time under a CC0 (public domain license).

Pelagios 3 and Recogito successfully met their aims and have drawn interest from potential stakeholders working throughout the humanities. These range not only across different periods and geographic regions, but between disciplinary fields (such as archaeology, classics and history), in diverse forms of text, and for the production and alignment of gazetteers to boot. Thanks to an Open Knowledge Foundation/DM2E Open Humanities Award, Recogito was also tested with several undergraduate student classes. This not only allowed us to refine its user interface, but also to see the various ways it changed students' approaches to, and understanding of, the material they were annotating. The very process of annotation, as many digital humanists can attest, forces a level of systematic reflection upon the annotator which might otherwise be elided.

Despite - indeed because of - Recogito's success, a number of limitations came to light during the course of Pelagios 3. First and foremost was its centralised architecture which provided a single workspace for all users. While well suited to a small team in regular communication with one another, the increasing number of users and documents meant that managing document metadata, preventing errors caused by concurrent edits, and keeping users abreast of changes to documents of interest became increasingly difficult. Furthermore, administrative tasks like uploading documents could only be carried out centrally, creating unnecessary barriers to use. Above all, while document copyright was protected through a restriction on public access, it was clear that if the system user base continued to grow over time, then the risk of copyright abuse would grow with it.

In addition to this central issue were a considerable number of feature requests which were not in the project's original scope of works and which we were unable to introduce within the time available. These include support for various input and output formats (including TEI XML, KML, and GeoJSON); the ability to add non-semantically defined commentary; overlapping annotations; simple points for identifying symbols on images (rather than textboxes for toponyms); competing interpretations of place references; and the ability to make annotated documents publicly available where copyright permits. With renewed financial support from the Andrew W. Mellon Foundation, the Pelagios initiative has been able to redesign and implement Recogito from the ground up in order to address these deficiencies and introduce additional features as well.

Recogito 2 presents an entirely new interface for the semantic annotation of place references. Users can self-register and are now provided with their own workspace (with an initial storage allowance of 200MB) in which they can upload and annotate documents. Each user's cataloguing page has its own URL and is publicly visible, although any uploaded documents are not. Documents can be uploaded singly or as a batch of related files (such as images of pages within a manuscript). Documents are automatically preparsed for possible place references at the upload stage unless the user declines to do so. Currently, Recogito 2 makes use of the Stanford NLP Toolkit (Manning et al., 2014), but we intend to make it extensible so as to support alternative parsing engines, such as the Classical Language Toolkit (Johnson et al. 2014-17) which may be better suited to specific languages or use cases. Whereas Recogito 1 only supported plain text documents and image files, Recogito 2 also supports TEI XML and images held in IIIF-compliant repositories, as well as JPEG, TIFF and PNG.

Once uploaded, an 'annotation view', allows the user to confirm automatically identified place references or create new ones (Figure 1). This takes place by means of a pop-up dialog box which determines the type of annotation (currently only places references, with free-text commentary and tags, but future development will include additional support for person references and events). Assuming the reference is to a place, the system proposes a probable gazetteer candidate which can either be confirmed or corrected as appropriate. Where the same place definition has been aligned across multiple gazetteers, these will be merged into a single entity for consideration, but the user is able to select which gazetteer they wish to formally associate the reference to.

Tell me, O muse, of that ingenious hero who tr
were the nations with whose manners and cust
his men safely home; but do what he might he
god Hyperion; so the god prevented them from
you may know them.

Many cities did he visit, and many
rying to save his own life and bring
folly in eating the cattle of the Sun-
ter of Jove, from whatsoever source

So now all who escaped death in battle or by sl
country, was detained by the goddess Calypso,
when the gods settled that he should go back to Ithaca; even then, however, when he was among his own people, his troubles were not yet over;
nevertheless all the gods had now begun to pity him except Neptune, who still persecuted him without ceasing and would not let him get home.

vas longing to return to his wife and
as years went by, there came a time

Now Neptune had gone off to the Ethiopians, who are at the world's end, and lie in two halves, the one looking West and the other East. He had gone there to accept a hecatomb of sheep and oxen, and was enjoying himself at his festival; but the other gods met in the house of Olympian Jove, and the sire of gods and men spoke first. At that moment he was thinking of Aegisthus, who had been killed by Agamemnon's son Orestes; so he said to the other gods:

Fig. 1. Recogito 2 text annotation view.

A major development in Recogito 2 is the introduction of 'social tools' for collaborative annotation. Annotators can share their documents with other registered users, allowing them to view, edit and create annotations dependent on the permission settings. Edits effectively act as discussion threads so that the full history of changes and commentary can be seen for each annotation (and where necessary, rolled back by the owner). We are also aware that for many users, producing Linked Open Data is not their primary objective. There are many other benefits to be derived from annotating place references, not least of which is the ability to map content. Recogito 2 offers a simple mapping interface that shows the distribution of place references - where coordinates can be derived from a gazetteer - against a range of possible backing maps. Symbol size reflects the number of references to the place, and selecting one provides the user with the specific references within the text itself (Figure 2).

Fig. 2. Recogito 2 map view.

A series of additional features replicate popular functions within Recogito 1. This includes a statistics dashboard, which provides data about both documents (such as place reference frequency, or the proportion of references lacking identification) and places (such as the toponyms by which they are referred to, and tags associated with them). It is our intention to add 'social statistics' that may allow people to see which of their documents are proving most popular or perhaps to help identify other users with similar interests. We have also extended the annotation download formats from solely CSV and RDF, to include KML, TEI and GeoJSON. This allows for their incorporation within a much wider range of software commonly used by humanists.

Already in public Beta-testing, Recogito 2 offers a next generation approach to semantic annotation of humanities documents with specific emphasis on place references. Nevertheless, we believe strongly that the value of this contribution lies not simply in its technical innovation but in facilitating community contributions to the Web of Linked Open Data.

Untangling the Social Network of Musicians

Stefan Jänicke
stjaenicke@informatik.uni-leipzig.de
Leipzig University, Germany

Josef Focht
josef.focht@uni-leipzig.de
Leipzig University, Germany

Introduction

As opposed to the former idea of creative autonomy, in recent years, humanities research tends to investigate cultural contexts and circumstances, inspirational models, and the ways that knowledge, experience and expertise have been transferred over time. We address the question of "creative transfer" within the field of music. Due to the everlasting significance of musical works, relationships between musicians – the entry point for such an investigation – are well documented in archives, libraries and museums. In print media, usually only a single relation between two musicians is narrated. Furthermore, it is common for the biography of only one of the two musicians to report on the relationship. Larger overviews of social networks between several musicians seldom exist. Although some digital resources exist, these are often reduced to the milieus of popular musicians like Mozart and Beethoven.

Since 2005, musicologists of the project Bavarian Musicians Encyclopedia Online (Bayerisches Musiker Lexikon Online, BMLO) have systematically collected biographical data (an example is given in Figure 1) and examined relationships between musicians from print media – a tedious work that results in a unique database of great value for musicology. The BMLO contains musicians from all kinds of musical professions (e.g., composers, singers, musicologists, instrument makers, ...), most of whom had an active lifetime period living in Bavaria or a considerable influence on Bavaria. Now providing information about around 28,000 musicians, the BMLO has achieved global scope, one that is underpinned by the many musicologists worldwide who use the BMLO for their daily work.

Figure 1: Biographical information about Robert Schumann in the BMLO. Alongside information about a musician's lifetime, denomination, professions or places of activity, the database provides a number of relationships by type. Next to his partner Clara Schumann, further relations are listed to Robert Schumann's father in law, to his students, colleagues, and other acquainted musicians in his social network

In earlier works, we developed visual interfaces on the basis of the BMLO data for profiling musicians (Jänicke et al, 2016), and for the distant reading of musicians' biographies (Khulusi et al, 2016). However, the social network inherent in the BMLO has remained untouched so far. Using the BMLO, only the social network of single musicians can be observed, as is the case when using print media. In order to facilitate an extensive analysis of the entire social network concealed in the BMLO, we designed a visualization that brings together all of the relationships in the form of an interactive social network graph. In contrast to previous means of investigating the transfer of musical knowledge, we allow for the dynamic exploration of relationships among musicians over generations.

Graph Topology

Information regarding relationships to other musicians in the database is provided for 9,805 musicians of the BMLO. Only one relation exists for around 46,5% of these musicians, and just 261 musicians have ten or more relations. Adolf Wilhelm August Sandberger is the musician with most relations (97). The average number of relations for musicians is 2.6. The resultant graph structure of the social network consists of 1,420 connected components, the largest component connects 5,539 musicians, the second largest only 56 musicians – 1,385 connected components contain less than ten musicians.

Due to the above mentioned topological features of the graph, the typical, straightforward visualization using a force-directed layout approach, e.g., by using tools such as Gephi (Bastian, 2009), leads to a global overview of the social network (see Figure 2). However, local structures are hardly readable, which makes an interactive exploration nearly impossible. The objective of this work was to develop a graph design that makes the social network of musicians visually accessible for the first time, and, moreover, capable of being explored in accordance with the research questions of the collaborating musicologists. We focused on the largest connected component that causes the greatest challenges for this task.

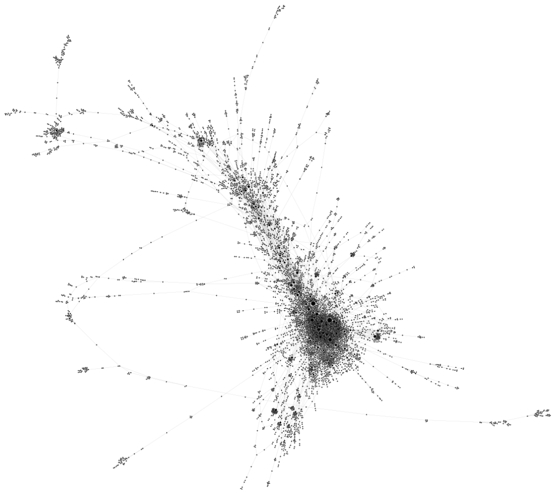

Figure 2: The largest connected component with 5,539 musicians visualized using Gephi.

Graph & Interface Design to Analyze Teacher–Student Relationships

The preliminary step when generating the social network graph is filtering according to the underlying research question. At first, a filtering can be done by relationship type(s). Second, it is possible to focus exclusively on musicians with specific professions (e.g., instrumentalists). In the following discussion, we focus on the motivating example for this work: the analysis of teacher-student relationships to investigate how musical knowledge, experience and expertise have been transferred over time. The corresponding filter keeps 3,994 musicians, the largest connected component of this sub-network – the research object of the musicologists – contains 2,769 teachers and students. The Gephi output for this graph is given in Figure 3.

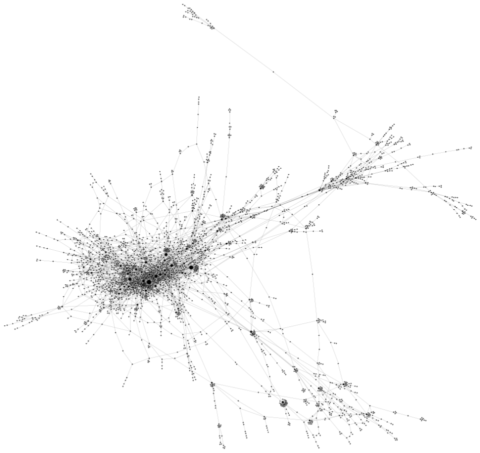

Figure 3: The largest connected component of the teacher-student network with 2,769 musicians visualized using Gephi.

Although the structures are slightly finer due to the reduced number of nodes and edges, the highly connected part in the interior of the graph remains cluttered. Here, we list our design decisions applied in order to generate a readable graph (see Figure 4) and a navigable interface.

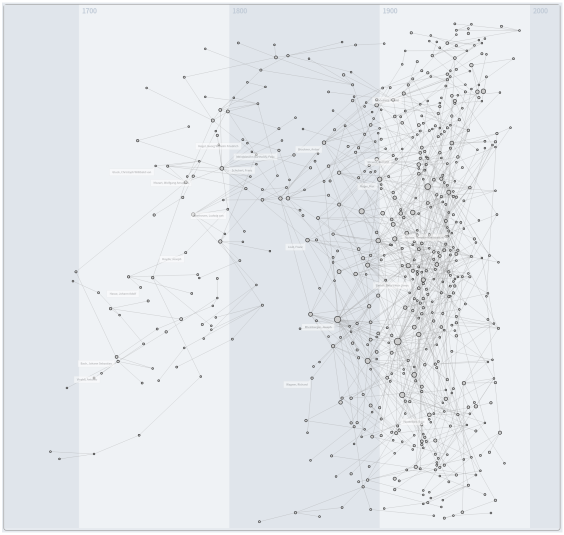

Figure 4: The largest connected component of the teacher-student network with 2,769 musicians (608 nodes) visualized with our method.

- **Temporally aligned graph:** It was particularly important for the musicologists that the graph layout includes a temporal dimension, so that relations can be chronologically analyzed from left-to-right. Therefore, we applied a force-directed graph layout and used fixed x-values that represent a time-stamp, which reflects the middle of a musician's creative lifetime (see Jänicke 2016), on a horizontal time axis. As a result, the nodes only spread vertically and the chronological order remains intact.
- **Node grouping:** Because the underlying research question investigates transfer paths of musical knowledge, we hide the nodes of musicians who never had the role of a teacher. Still, these musicians are grouped to their teachers, and can be accessed in the exploration process. This design decision reduces the number of nodes to be displayed from 2,769 to 608.
- **Node layout:** To illustrate the significance and the influence of personalities, the sizes of nodes reflect the number of students of the corresponding teachers, which makes teachers with many students salient. Per default, node labels are hidden, but for navigation purposes, a user-defined number of node labels with the corresponding musicians names can be shown on demand. Either the most popular musicians or the teachers with most students can be highlighted.
- **Interactivity:** Hovering over a node shows the corresponding musician and two lists of students (those who became teachers and those who did not) in a popup box. Clicking a node highlights all connections to a teacher's students who became themselves teachers. This way, transfer paths of musical knowledge can be assembled interactively.
- **Musical profession analysis:** For the selected (via mouse click) musicians in the graph, the evolution of musical professions can be analyzed. Therefore, all musical professions of the teachers' students are listed by decreasing frequency. For each profession, a bar chart illustrates when they have been pursued.

Analysis of Teacher–Student Relationships

This section outlines a usage scenario of the teacher-student network taking the example of Adolf Wilhelm August Sandberger who established musicology as a subject of study in Munich.

First, we compare Sandberger to one of his teachers, Joseph Rheinberger, both being the teachers with the highest numbers of students (the BMLO lists 97 students for Sandberger and 87 students for Rheinberger). Of special interest was the comparative analysis of the musical professions of their students in order to assess the similarity of both teachers' studentries. Figure 5 shows the two selected teachers in the social network, and a view at the summarized musical professions of their students is given. While composition was the major musical profession of Rheinbergers students (70x), this number drops for Sandbergers students (52x). On the other hand, the number of musicologists increase (10x → 65x). Other significant changes can be seen for the professions choirmaster (29x → 9x), organist (19x → 8x), music writer (12x → 29x) and music editor (5x → 26x). Thus, the visualization reflects a change of the musical profile of both studentries from composition to composition science– a hypothesis that could be verified with our system.

Second, we examined the change of teaching since Sandberger established musicology in Munich. Therefore, we observed the musical professions of the students of Sandberger and his successors in Munich, Rudolf von Ficker, Thrasybulos Georgios Georgiades and Theodor Göllner (see Fig. 6). While the musicologist is the most frequent taught musical profession, the composer gets less and less important. The last teacher Theodor Göllner even had no student with the composer as musical profession. Thus, the change from composition to composition science that already started with Sandberger compared to Rheinberger, steadily continued with Sandberger's successors.

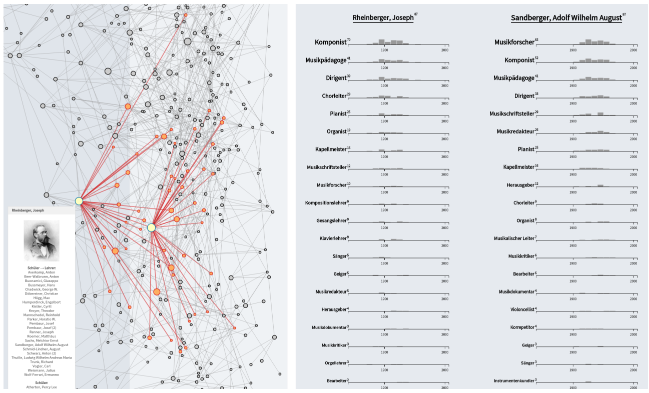

Figure 5: Comparing the students of Joseph Rheinberger and Adolf Wilhelm August Sandberger.

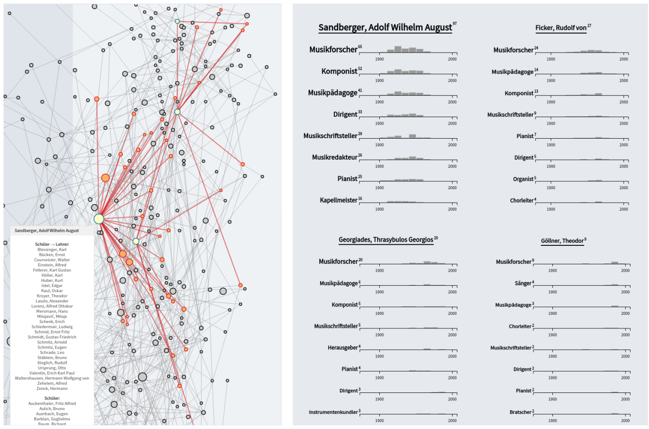

Figure 6: Temporal change of teaching in Munich.

Conclusion

Through close collaboration with computer scientists and musicologists implementing a user-centered design approach, we developed a visualization that allows for the dynamic, interactive exploration of the social network of musicians, focusing primarily on teacher-student relationships. In contrast to out-of-the-box tools like Gephi, we took the research questions of the collaborating musicologists into account when designing the graph and the user interface. Although detailed information about individual relation periods between musicians as well as the taught musical professions are not included in the underlying database, the provided interface facilitates a novel view on the social network of musicians, which allows to draw conclusions on the question of the transfer of musical knowledge.

The value of our system for users of the BMLO is not only that social networks are visualized for the first time, but also that the graph may be filtered in accordance with the way that specific research questions can be investigated. Next to teacher-student relationships, familial or labor relationships also create valuable networks to be explored. Furthermore, it is possible to analyze sub-networks concerning musical professions, and to combine relationship types with musical professions. For example, when combining teacher-student relationships with the musical profession *instrumentalist* (see Fig. 7), Wolfgang Amadeus Mozart shows up at the beginning of the instrument playing knowledge transfer.

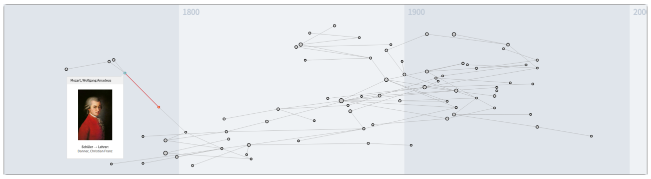

Figure 7: Teaching instrumentalists.

Introduction

MoEML's gazetteer of 6500 London place name variants invites the mapping of datasets with a geographical component. As a textual editing project with an interest in print culture, we have long hoped to mobilize our GIS tools and gazetteer data in the service of mapping the English book trade. Our ultimate goal is to publish a layer showing the printing and/or retailing locations of the approximately 25,000 books printed in London between 1475 and 1640.

Imprint lines in early modern books include highly granular location data, which has meant that book history has traditionally had an implicit geospatial dimension. A typical imprint line tells us that copies of a folio are "Printed by Elizabeth Purslovv, and are to be sold by Nicholas Bourne, at his shop at the south entrance of the Royall Exchange, 1633." Using the information in such imprint lines, Kathleen Pantzer reorganized the items in the Short Title Catalogue under location headings (Pantzer numbers) in Vol. 3 of the catalogue. Her work facilitates questions about the proximity of one printer or bookseller to another, and thereby questions about affiliations, collaborations, and specialization among a key group of early modern cultural agents.

However, considerable processing of Pantzer's printed lists is required to visualize or map STC items. Thus far, digital databases like *Early English Books Online* (EEBO) and the *English Short Title Catalogue* (ESTC) have captured the imprint line without parsing it into discrete data points, thereby leaving Pantzer's formidable interpretive work behind as we move into the era of digital historical bibliography. *The Database of Early English Playbooks* (DEEP) has included and corrected Pantzer numbers, but only for the printed plays, of course. MoEML has attempted to replicate Pantzer's work via datamining the ESTC. After several unsuccessful NER experiments on ESTC data, we are now mobilizing the curatorial work of DEEP and planning to extend their work beyond playbooks. In this paper, we take imprint lines and geospatial information about the book trade as a case study in mining carefully curated data. We explain the long history of this project as it extends back to Pantzer's own work creating the strict vocabulary for the print locations of early modern texts. We then discuss how MoEML has been able to put the STC data onto the Agas map, giving a better sense of the spatial relationship of printed early modern texts. In doing so, our argument centers on the necessity for authority names and strict vocabularies. Invoking Mike Poston's suggestion that we cannot predict the uses of our data, we use our own work on various print and digital databases to show how we can control and scaffold the mining processes to establish links between several pairs of projects in order to mine and ingest data from databases that do not share a common data field with the initial project in the sequence. We conclude with a list of considerations and principles for maximizing future interoperability between literary datasets.

Methodology

Although not strictly based in MySQL technology, our methodology borrows from the work of digital humanists like Harvey Quamen and Jon Bath who use MySQL to design relational databases. Indeed, in order to establish valuable connections across diverse datasets, we must first identify what data points these datasets have in common (either directly or indirectly). For example, suppose that Dataset 1 contains raw data for categories A, B, and C and Database 2 contains raw data for categories X, Y, and C. By identifying common data points in category C between databases 1 and 2, it becomes possible to make further connections among categories A, B, X, and Y. From here, we could identify common data points in a third database that contains raw data for categories E, F, and X. We believe that relational databases provide the best platform to capture this "web of relations" in big data. Quamen and Bath describe relational databases as "a series of interconnected spreadsheets. Each spreadsheet--called a table in database lingo--contains information on a real world entity such as People or Books or Songs or Birds or Rock Concerts or Places. Those tables are then tied together via relationships" (Quamen and Bath, 2016; 146-147). By providing a set of stepping stones or crosswalks between diverse datasets, relational databases enable us to build links between allied projects (i.e., ones that share a common data point) and more remote projects (i.e., ones that do not share a common data point) in order to combine expertise and mobilize already curated data in new environments.

Past Work

In 2014, MoEML research assistant Tye Landels-Gruenewald undertook a directed study course with director Janelle Jenstad with the aim of geocoding the *English Short Title Catalogue* (ESTC) from 1475 through 1666. With the generous assistance of David Eichmann and Blaine Greteman of the Shakeosphere project (based at the University of Iowa), we were able to extract toponyms from transcribed imprints in the ESTC catalogue using natural language processing (NLP) technology. We had intended on using named entity recognition to find matches between the extracted ESTC toponyms and our own gazetteer of early modern London locations; however, the toponyms themselves included too many errors or extra text to make this feasible. As Grover, Givon, Tobin, and Ball note in their white paper on "Named Entity Recognition for Digitised Historical Texts," there is still much work be done in order to teach named entity recognition software to recognize early modern English (Grover et al., 2008).

Concomitantly, Jenstad was manually compiling a spreadsheet of Pantzer numbers and cross-referencing them to MoEML location identifiers. Pantzer numbers are an alphanumeric string consisting of a letter and an integer. The letter indicates a general location. All the Pantzer numbers beginning with the letter O indicate locations in, near, or "against" the Royal Exchange. The numbers offer more granularity. For example, O.2 designates a location "at the north side of the Royal Exchange." Key challenges in matching Pantzer numbers with MoEML IDs were (1) different controlled vocabularies, and (2) the different levels of granularity inherent in the projects. Pantzer's authority names came from the imprint line wording; MoEML authority names are standardized spellings of the official or most common toponym variant (determined by set of critical rules we codified in order to build our gazetteer). Granularity differences emerged from the different interests of the two projects. Book historians map the bookstalls in the Royal Exchange, a location for which MoEML considered as a single entity (ROYA1); MoEML finer granularity emerges elsewhere, in our mapping of conduits, landings, and the many other precise locations that John Stow mentions in his Survey of London. A full crosswalk between Pantzer and MoEML would require the addition of sublocations to MoEML's placeography, a goal we will likely realize via the development of MoEML microsites for the Royal Exchange and Paul's Churchyard. In the meantime, we lose some of the granularity of Pantzer's data by assigning the same MoEML id to two or more Pantzer numbers.

Current Work

These past-attempts at establishing interoperability between datasets illustrate the challenges in attempting to traverse projects that only weakly share common data points. Between MoEML and the ESTC are a number of assumptions, potential errors, and remediations that weaken the link between the two respective datasets. To get to our larger project of mapping the STC, we must take smaller steps.

Our current work relates the playbook data collected by Zachary Lesser and Alan B. Farmer at *The Database of Early English Playbooks* (DEEP) to our own toponymic data, relying on Pantzer's vocabulary as a shared data-point. Jenstad's spreadsheet was transformed into a TEI-conformant XML table, which we ran across DEEP's openly available XML data. Doing so allows us to integrate DEEP numbers into the site, linking outwards to DEEP's newly static and predictable URLs.

The DEEP data and Pantzer-MoEML table can be related, but we recognize that this relationship is not immutable. In other words, both datasets are "living" databases insofar as the data can—and should be—curated and edited. Once Jenstad's spreadsheet was converted into TEI, Landels-Gruenewald was tasked with editing and refining Jenstad's initial findings to reflect the the growth of MoEML's gazetteer over the past two years (the MoEML team tagged nearly 2000 more toponyms between July 25, 2014– the last day Jenstad worked on the spreadsheet– and October 31, 2016, from 11,259 to 16,120). Lesser and Farmer have also recognized the need to amend Pantzer's findings in their data.

Future Work

The experiment with DEEP data has given us a stronger link to the ESTC. Now that we know Pantzer numbers are relatable to MoEML toponym IDs, we can now mobilize the data from Pantzer's appendix to connect MoEML with the ESTC. We plan to convert Pantzer's printed aggregations of STC numbers to digital files via OCR. With some curation, we will then have a list of all the STC numbers at each Pantzer number; using our crosswalk between Pantzer numbers and MoEML IDs, we will have a list of STC numbers (and therefore of unique print editions and issues) associated with MoEML locations. From the ESTC, we can obtain a crosswalk relating STC numbers to ESTC numbers. We add the caveat that Pantzer's locations will need to be corrected as book historians like Lesser and Farmer bring their knowledge to bear on her interpretation of STC data; every crosswalk dependent on her data will need to be refreshed and all the data maps remade. We can display these STC numbers as lists on MoEML location pages, much as Pantzer's print database does; in the digital environment, we can make dynamic links to DEEP or ESTC open-access pages for the book. We can also map these numbers on our open-layers Agas map platform as a layer of imprints associated with locations, eventually in combination with other tags (such as genre, now being added to EEBO by other scholars) or with other metadata fields harvested from the ESTC. All this data will pivot on the STC-MoEML data crosswalk that we are producing via Pantzer, following DEEP's initial work.

Distant Future Work

A longer-term goal is to harvest from the ESTC's XML files the strings of characters transcribed in the imprint line metadata field. Since we will already know from the STC-MoEML crosswalk which location is described in the imprint line, we can sort the imprint lines by locations and do rapid human scans for outliers, which may be a quick way of correcting Pantzer's data. We can also wrap TEI tags around the toponyms in the imprint lines, thereby increasing the number of toponymic variants in the MoEML gazetteer. The more variants in the gazetteer, the more accurate any future NER or geoparsing of large corpora will be. Given that we already search the EEBO-TCP corpus manually for references to place, we aspire to run our gazetteer against the entire TCP corpus to find and then map toponyms.

Principles and Practices of Curation for Future Mining and Interoperability

Acknowledging that the most interesting future uses of a project's data have not yet been imagined (Poston, 2011), how can we maximize the opportunities for other people to do things with that data? We suggest the following principles and practices as a starting point for discussion:

1. Make your data free to the world, preferably in easily downloadable and manipulable formats (in .json or .xml files, for example).
2. Be clear about how you compiled your data.
3. If you are aware of limitations in your data, tell the world.
4. As you correct and refine your data, communicate regularly about data updates.
5. If you are using other people's data in your own applications, check back regularly and rebuild the data crosswalks.
6. Know the weak link(s) in your data crosswalks.
7. Plan for corrections as other projects improve their data.

8. Be mindful of the potential for error to compound. Errors in my data, combined with errors in your data, have the potential to lead scholars to false conclusions.
9. Test your data crosswalks in a variety of ways. Take a small subset of the data and compare NLP results to hand curated results, for example.

Conclusion

Pantzer died in 2005, the year before MoEML was published at a public URL, but we like to think that she would have welcome the digital recreation, correction, curation, and connection of her data. She used the capacities of print to create a map and dense cross-references. Having "o'erleapt" Pantzer's curatorial work in building our digital catalogues, we now need to capture her formidable scholarship of interpreting and relating disparate types of data. We began with the goal of relating MoEML toponyms to ESTC numbers, but discovered that Pantzer's hand-curated data was more reliable than the results of NER and NLP. Our new question then became: "What sort of steps, processes, principles, and practices are necessary in doing this sort of work?" Handcrafted data, in conjunction with computer processing, allows for greater interoperability between projects and begins to achieve the possibilities of the data not conceived by Pantzer.

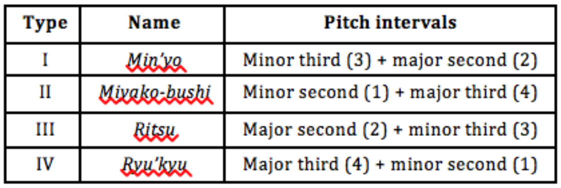
Regional Classification of Traditional Japanese Folk Songs from Southwest Regions

Akihiro Kawase
akawase@mail.doshisha.ac.jp
Doshisha University, Japan

Introduction

The main purpose of this study is to grasp the pitch transition patterns from pieces of traditional Japanese folk songs among southern three regions of Honshu (the Main Island of Japan), and by making comparisons with Koizumi's tetrachord theory in order to make the regional classification by the tendency in pitch information.

A tetrachord is a unit consisting of two stable outlining tones called kaku-on (nuclear tones), and one unstable intermediate tone located between the nuclear tone. Influenced by the methods of Western comparative musicology, the Japanese musicologist Fumio Koizumi conceived of a scale based not on the octave unit but rather on the interval of a perfect fourth, and has developed his tetrachord theory to account traditional Japanese music (Koizumi, 1958). Depending on the position of the intermediate tone, four different tetrachords can be formed (see Table 1 and Figure 1).



Type	Name	Pitch intervals
I	Min'yo	Minor third (3) + major second (2)
II	Miyako-bushi	Minor second (1) + major third (4)
III	Ritsu	Major second (2) + minor third (3)
IV	Ryu'kyu	Major third (4) + minor second (1)

Table 1. Koizumi's four basic tetrachords.

In the previous study, we have sampled and digitized the five largest song genres within the music corpora of the Nihon Min'yo Taikan (Anthology of Japanese Folk Songs, 1944-1993) from 45 Japanese prefectures, and have clarified the following three points by extracting and comparing their respective musical patterns (Kawase and Tokosumi 2011): (1) the most important characteristics in the melody of Japanese folk songs is the transition pattern, which is based on an interval of perfect fourth pitch that constructs Koizumi's four basic tetrachords; (2) regionally adjacent areas tend to have similar musical characteristics;

and (3) the differences in the musical characteristics almost match the East-West division in the geolinguistics or in the folkloristics from a broader perspective. However, to conduct more detailed analysis in order to empirically clarify the structures by which music has spread and changed in traditional settlements, it is necessary to expand the data and make comparisons based on the old Japanese provinces (ancient administrative units that were used under the ritsuryo system before the modern prefecture system was established).

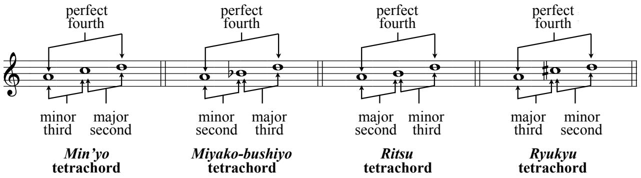


Figure 1. Example of four different types of Koizumi's tetrachord when taking A-D as kaku-on (nuclear tones).

Overview of data

We extracted the musical notes for works included in the "Nihon Min'yo Taikan", and digitized the entire scores from each province in the Kyushu district (geographically located in the southern part of Japan), Chugoku district (the westernmost region of Japan's largest island of Honshu), and Shikoku district (literally meaning four provinces, located south of Honshu and east of Kyushu district). In total, there were 474,191 tones in the sample of 2,383 songs for the 25 provinces (see Figure 2).

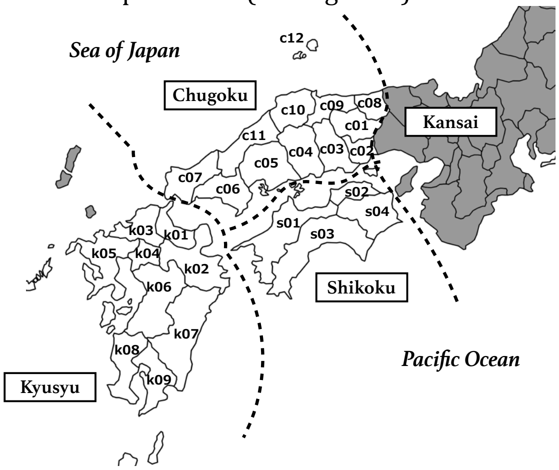

Figure 2. Geographical divisions of the three districts under the old provinces

Procedure

The procedures are as follows: (1) we digitized all the songs from each district and generated sequences that contain interval information from the song melodies; (2) extracted four transition probabilities of tetrachords for every province separately, and create a 24-dimensional data with 25 samples (provinces); and (3) applied principal components analysis (PCA) to identify patterns in the data, and to highlight their similarities and differences.

In order to digitize the Japanese folk song pieces, we generate a sequence of notes by converting the music score into MusicXML file format. We devised a method of digitizing each note in terms of its relative pitch by subtracting the next pitch height for a given MusicXML. It is possible to generate a sequence T that carries information about the pitch to the next note: T = (t1, t2, ... , ti, ..., tn). An example of the corresponding pitch intervals for ti can be written as shown in Table 2. We treat sequence T as a categorical time series, and execute N-gram to capture transitions and their trends.

Using a bigram model representing pitch transitions, all four types of tetrachords from Table 1 can be expressed as follows in ascending order: min'yo (+3, +2), miyako bushi (+1, +4), ritsu (+2, +3), and ryukyu (+4, +1). Depending on the positions of the three initial pitches in a tetrachord, six transition patterns can be considered in perceiving a tetrachord in two steps (bigram). Therefore, the amount of tetrachords within two steps can be obtained by counting the pairs of 24 transition patterns in sequence T.

t_i	Pitch Intervals	t_i	Pitch Intervals
0	perfect unison	7	perfect fifth
1	minor second	8	minor sixth
2	major second	9	major sixth
3	minor third	10	minor seventh
4	major third	11	major seventh
5	perfect fourth	12	perfect octave
6	aug.fourth/dim.fifth	13	minor ninth

Table 2. Corresponding pitch intervals

Results and discussions

The relative frequency of the first transition (unigram), is maintained between "-5" and "+5"; the interval of a perfect fourth pitch (see Figure 3). As the graph forms a symmetric shape with respect to "0", the pitch transitions occur almost equally in both descending and ascending order.

The implementation of the PCA is summarized as follows. As shown in Table 3, the component loadings for the first three principal components of each province explain more than 85.88% of the variability.

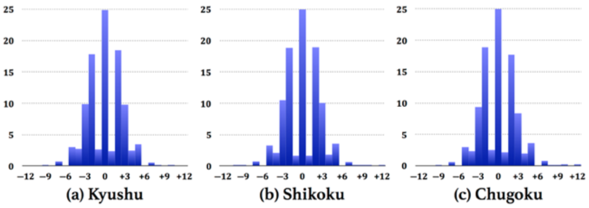

Figure 3. First transition frequencies for three regions

In the first column, the values of all 24 variables represent a positive quantity, and have almost the same weight. This result indicates that the profile of the first PCA axis is the persuasiveness of the tetrachord. Thus, as the value increases, the inclination of a pitch transition enhances its persuasiveness, and the value decreases, it loses its persuasiveness. In the second column, all variables for the min'yo and the ritsu represent a negative quantity, while 11 variables for the miyako-bushi and the ryukyu represent a positive quantity. According to ethnomusicological research, the min'yo and ritsu tetrachords appear frequently in Japanese folk songs. In contrast, the miyako-bushi and ryukyu tetrachords, steadily shifted from the ritsu and min-yo tetrachords respectively, and then increased in popularity as an emotional crutch (Koizumi, 1977). This result indicates that the profile of the second PCA axis is the relative pitch intervals between the nuclear tone and its intermediate tone, or in other words, the differences in patterns of transition from the nuclear tone. Thus, as the value increases, the adjacent intermediate tone forming the tetrachord tends to form a minor second interval (sort of a minor key progression), and as the value decreases, it tends to form a major second interval (sort of a major key progression).

The corresponding scores for each sample are plotted in a two-dimensional space to complete the PCA (Figure 4). We see that there is a strong contrast between min'yo, ritsu, miyako-bushi, and ryukyu. It is possible to clarify the structural commonalities and differences between areas. Figure 5 is the result of applying the hierarchical cluster analysis (Euclid distance, Ward method) to the corresponding scores. In addition, if we look for a height where there are three vertical lines and trace the lines down to the individuals, the partition corresponding to three clusters. If we plot this result on a map, we see that provinces are clearly classified according to geographical factors and cultural backgrounds (Figure 6).

Variables		1st PCA axis	2nd PCA axis	3rd PCA axis
minyo-1	(+3, +2)	0.947	-0.224	-0.021
minyo-2	(+5, -2)	0.893	-0.330	-0.136
minyo-3	(+2, -5)	0.879	-0.340	-0.136
minyo-4	(-3, +5)	0.888	-0.204	-0.151

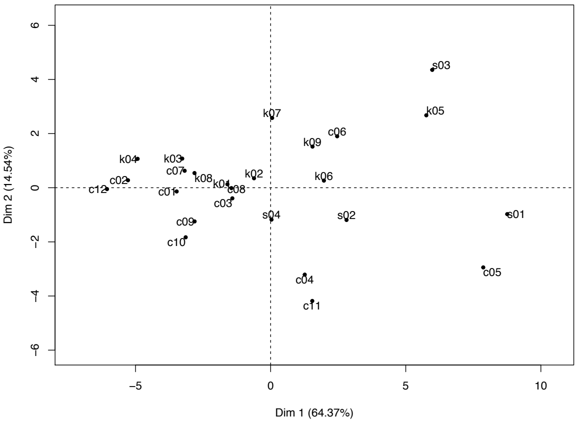

Figure 4. Plot of the first two component scores

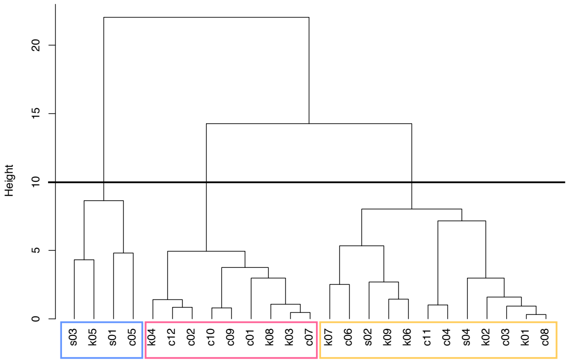

Figure 5. Dendrogram based on component scores using Ward method

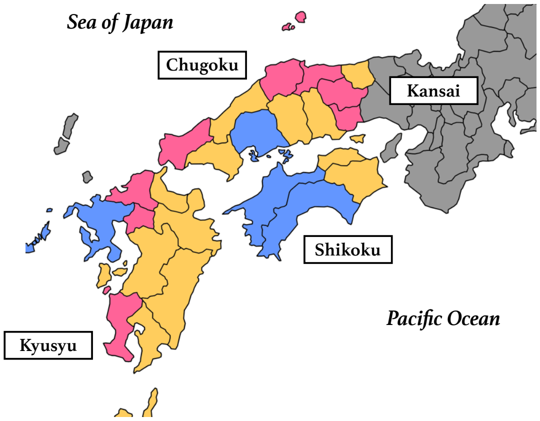

Figure 6. Clustering results plotted on a map

Conclusion

In this study, we digitized the melodies of endangered traditional Japanese folk songs from three regions, and quantitatively classified them according to the old province by executing principal components analysis and hierarchical cluster analysis in terms of pitch transitions based on a unit of Koizumi's tetrachord theory. As a result, compared to our previous studies on the small amount of data (e.g. Kawase 2016a, 2016b, 2016c), regions were successively classified according to both geographical factors and cultural backgrounds in detail, and classified the melodies into two basic groups according to the behavior of the intermediate tone. We firmly assured that the melodic structures of tetrachords in each province are shared by land and sea routes based on actual music data analysis.

Quotidian Reading: Digitally Mapping Literary and Personal Geographies

Tom Keegan
thomas-keegan@uiowa.edu
University of Iowa, United States of America

Sarah Bond
sarah-bond@uiowa.edu
University of Iowa, United States of America

Students (and some teachers) feel rightly intimidated by Petronius' *Satyricon* or James Joyce's *Ulysses*. They are big books that are too often cast as *things* to be conquered or "done"— as in " I did *Ulysses*"—rather than encountered as portals to better understanding ourselves and the world in which we live. In the face of literary complexity and historical heft, students and instructors experience an anxiety of knowing. They feel expected to master a text rather than adapt it to their own needs or desires. In this long paper, we (Professors Sarah Bond and Tom Keegan) offer an alternate approach to reading texts in which the experiential learning advocated for by John Dewey (and often averred by literary theorists) is combined with a host of digital mapping tools, broadly understood. We describe our work in two courses—one in Classics and one in English—as aimed at connecting the content of Petronius' and Joyce's novels with the daily lives of our students. In our courses students undertook a kind of "quotidian reading" in which they identified spaces and practices in the novels and relocated those elements in their own lives, sharing their observations through mapping, blogging, and podcasting. The resulting coursework reversed the emphasis on knowing the text as thing, and placed it, instead, on knowing the text as a mode of self-understanding. Given both Joyce's and Petronius' preoccupation with space and geography, we invited students to map their own daily travels, applying the text as epically or mundanely as they saw fit. We were interested in how students came to see the text as relevant to them as everyday people.

This student-driven cartography in which real spaces are interpreted alongside "imaginary" spaces via digital means encourages humanities students to close the gap between what they are reading and what they are living. Quotidian reading has the potential to refigure all types of textual spaces—from the *Aeneid*'s description of the underworld to Dante's description of it over a millennium later—by inviting students to annotate and augment their spatial dynamics with textual references—and vice versa. In this paper, we lay out a set of best practices, digital methods, and core approaches to allowing students to thread the "imagined spaces" of the text into the daily spaces of our students' lives. Digital tools offer intriguing possibilities for reframing the stoic and epicurean spaces embedded in the *Satyricon* or resituating the daily environments and existential perspectives of *Ulysses'* Bloom, Stephen, and Molly. As our students mapping (among other things) the use, disuse, and misuse of public spaces in Iowa City, they approach a new understanding of Petronius' satirical spaces or Joyce's novel articulation of the public sphere. Through the use of the open-source tool "ImageMapster," which uses HTML5 canvases rather than Java in order to work in modern browsers, students represent, annotate, layer, and ultimately archive these literary topographies. The process allows students to engage in memoir through the geographic medium of the map and to remediate their experience of their daily life—in much the same way that Petronius and Joyce did. One result, has been the creation of personal "base maps" for the literary texts as constructed by our students. This product of the pedagogical enterprise suggests a new approach for commonly taught literary texts in other courses. Standards for the mapping of literary geographies as personal geographies are virtually non-existent, though they are a means for both engagement and reflection.

In some ways, this paper moves the application of GPS beyond Bill Clinton's 1996 desire to "encourage acceptance and integration of GPS into peaceful civil, commercial and scientific applications worldwide.” That broad public intent, combined with the pedagogical legacy of the “spatial turn” in literature, history, and art, has yielded a growing interest in digital humanities projects that make use of mapping as a tool of self-discovery. The pedagogical approach detailed in this paper expands on spatial turn’s address of the “microcosms of everyday life and the macrocosms of global flows.” And while cartography provides the ability to relate points spatially as they exist on the Earth’s surface, literature often deviates from the physical geometries denoted through longitude, latitude, and elevations coordinates. Through a quotidian reading, the spatial structure and topographical features found within novels such as Petronius’ *Satyricon* or James Joyce’s *Ulysses* help students organize, access, and navigate literary texts and themselves in daily life. The frequent tensions between the “real” and the “imaginary” geographies of a text and of our everyday lives can—when reflected upon—serve to unveil to students the emotions, perceptions, and motives of a character or author. This paper, we hope, will invite thoughtful conversation about the nature of the digital humanities in and beyond the classroom, as students are encouraged to see digital tools as ones they can use in everyday life.

Did a Poet with Donkey Ears Write the Oldest Anthem in the World? Ideological Implications of the Computational Attribution of the Dutch National Anthem to Petrus Dathenus

Introduction

The *Wilhelmus* has been the official national anthem of the Kingdom of the Netherlands since 1932. The song carries a wider relevance that extends well beyond the Low Countries. According to the authoritative *Guinness Book of Records*, the *Wilhelmus* is the national anthem with the oldest music in the world: we are able to date the tune and text to the years 1568-1572 during the Dutch Revolt, a key episode in the history of the Early Low Countries. Moreover, in the song’s fifteen couplets, an anonymous poet has immortalized a dramatic internal monologue of William the Silent, Prince of Orange (1533 – 1584), a well-known figure who has played a decisive role in the political history of Europe (Van Stipriaan, 2007).

In the earliest sources, the *Wilhelmus* has invariably survived anonymously, in print collections of rebel songs (the so-called *geuzenliederen* or ‘beggar songs’) that date back to the Spanish Occupation in the Low Countries (De Bruin, 1998). Only some of these songs are attributed to known authors; the majority, including the *Wilhelmus*, are not. Apart from the supposed date of composition (1568-1572), there are few historical facts that could help the attribution. Although the *Wilhelmus* does not explicitly choose sides in contemporary religious conflicts, circumstantial evidence strongly suggests that the text was written by an author of Flemish or Dutch descent, who was living in a German refugee community at the time, perhaps in the vicinity of Heidelberg, because of a number of striking intertextual connections to other songs that were composed in that area.

Ever since its creation in the late sixteenth century, the attribution of the song has not ceased to puzzle scholars as well as other inhabitants of the Low Countries. Only decades after the song’s composition, there seems to have been considerable confusion already: in various sources, we find widely divergent attributions of the song to a number of famous authors, such as Marnix of Saint Aldegonde (the mayor of Antwerp, during the city’s famous Fall in 1585) or the religious author and philosopher Dirck Coornhert. Many other candidate authors would be suggested in the next centuries, the credibility of which could vary strongly. In the public opinion, Marnix has long remained the most popular candidate, although scholars have never reached any definitive agreement on the issue. As late as 1996, for instance, an entire doctoral thesis was devoted to the authorship of the *Wilhelmus*. In this thesis, Maljaars predominantly argued that Marnix could not have been the author, relying on traditional evidence: the results of the close reading of the Wilhelmus, and comparison between the *Wilhelmus* and other texts by the presumed author(s).

In 2016 an interdisciplinary team of scholars has tackled this age-old issue from a new perspective: stylometry. For most of the candidate authors which have been suggested for the *Wilhelmus*, we have available relatively sizable oeuvres of lyrical poems or even highly similar songs. The comparison of the *Wilhelmus* to those reference oeuvres, using state of the art stylometric methodologies, should allow us to estimate the relative distance from the anthem to each candidate author (*authorship attribution*) and verify their authorship (*authorship verification*). Many issues, however, make this comparison far from trivial: the texts are short (the *Wilhelmus* only counts 500 words), we only know younger, potentially corrupted versions of the texts and rarely have autographs, the spelling of the material is highly unstable etc. We have tried to tackle the latter issue through part-of-speech tagging and lemmatizing the texts (Kestemont et al., 2016b): instead of performing measurements on the original surface forms, we would restrict our analyses to the most frequent tag-lemma pairs (MFTLPs), which normalize the spelling of tokens.

In this paper, we will report several authorship experiments, using both the attribution and the verification setup (Kestemont et al., 2016a), in which we have compared the *Wilhelmus* to a representative set of contemporary authors, among which the main candidate authors as well as some background authors that merely served as 'distractors' or 'imposters'. We include a small selection of these below. Surprisingly, these experiments without exception pointed towards an obscure, vilified author who has never even been mentioned as a candidate author: Petrus Dathenus (ca. 1531-1588). The first series of plots are rather naive Principal Components analyses (300 MFTLPs) which each confront textual samples by two candidate authors and the *Wilhelmus* (in white). In these binary comparisons, the *Wilhelmus* is attributed to Dathenus without exception. The same goes for the verification experiment (which runs entirely parallel to the experiments run on the Caesarian corpus in Kestemont, et al. 2016a): when compared to both target and imposter authors, the *Wilhelmus* is significantly closer to Dathenus's texts than to any other candidate author from this period for which we have texts available.

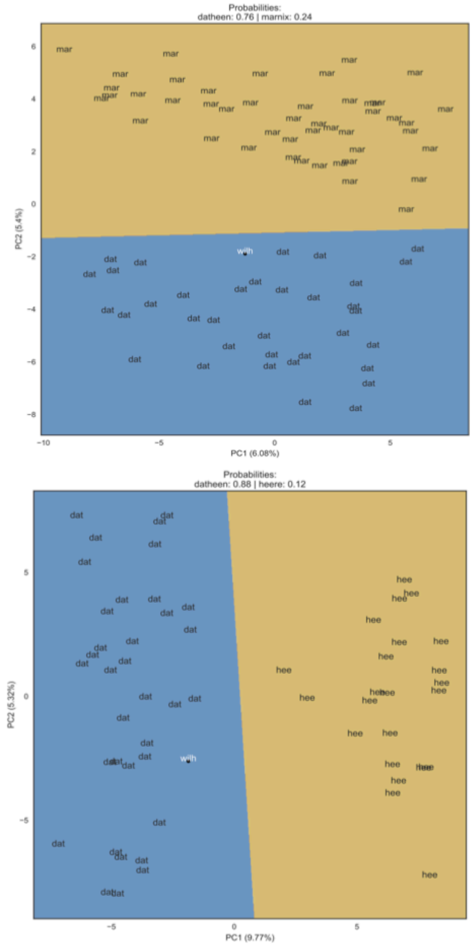

Fig. 1: Naive 2-dimensional PCA plots in which textual samples by two authors (Datheen vs Marnix; Datheen vs Heere) are confronted, including the *Wilhelmus*.

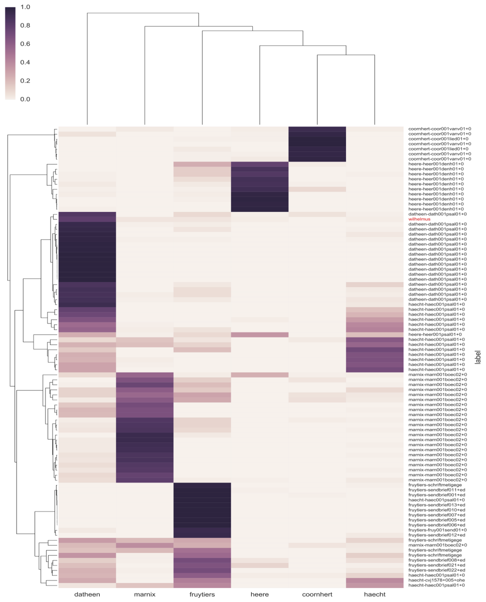

Fig. 2: Cluster map for the verification results obtained for the *Wilhelmus* and a number of highly relevant candidate authors (Kestemont et al. 2016a).

Dathenus is primarily known as the author of a complete Dutch adaptation of the Psalms, which became extremely influential in the second half of the sixteenth (and which is in fact still sung today in some reformed communities). His contemporaries considered him a great and dangerous orator because of his convincing way with words. Nowadays, Datheen has the reputation of being a very poor poet. To what does he owe this bad reputation? Our present-day image of the man goes back to the late eighteenth century when the pressure grew to have his Psalm adaptation replaced by a more modern one in churches. In order to increase the pressure on Dathenus's Psalms, people started mocking the poet through the dissemination of caricatures in which the man would even be depicted with donkey ears (see Fig. 3). It is striking how strongly our present-day view of Dathenus is still determined by the highly anachronistic eighteenth image of this author, instead of that of the respected and influential individual he was known to be in his own time.

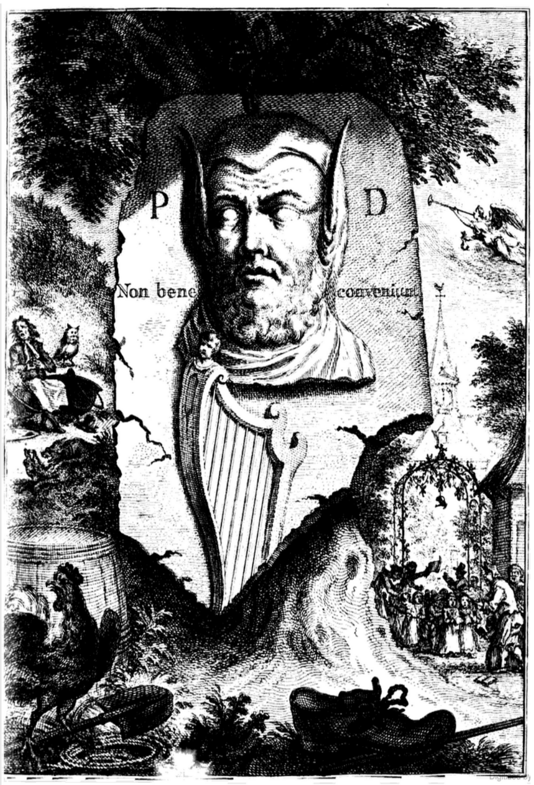

Fig. 3: A late eighteenth century caricatural depiction of Petrus Dathenus with donkey ears, to symbolize his alleged poetical ignorance.

In this paper, we will re-assess the sparse, historical evidence that is available for Petrus Dathenus and show that he is, in fact, an unusually strong authorial candidate for the *Wilhelmus*. Here, we limit our discussion to a single new fact that recently emerged. The *Wilhelmus* is a so-called contrafact: the song has been composed by writing a new set of lyrics for an already existing melody, a very common practice in early modern song culture. The original melody which was used for the *Wilhelmus* was a French song: *O la folle entreprise du Prince de Condé*. Musicologist have been able to pinpoint when this song was created: it must have been composed (as a Protestant song) during the Siege of Chartres in 1568. The tune must have been introduced in the Low Countries via the *Wilhelmus* and was not known beforehand. Therefore, it has always puzzled scholars how the *Wilhelmus* author might have been exposed to this French tune. Intriguingly, it turns out that Dathenus must have been present at the Siege of Chartres as a field preacher on the protestant side. Thus, although he has never made it to the official candidate list, Dathenus is in fact the only candidate, who not only has the right stylistic profile, but of whom we also argue that he was directly exposed to the base tune of the *Wilhelmus*.

In our paper, we will not go as far as to claim that the neglect of Petrus Dathenus as a potential candidate author for the national anthem of the Netherlands has been an ideological 'cover up operation'. We will discuss, however, the anachronistic biases and prejudices which so far have prevented the identification of Petrus Dathenus as a potential candidate author. From the point of Digital Humanities, it is important to stress that we base this research on a bold computational attribution to an author who, at first sight, seems a highly unlikely candidate; a human expert would never even have dared to think of this attribution. Nevertheless, exactly because machines do not carry the same set of preconceptions as humans, the application of stylometry is able to induce serendipity in humanities research and open up new perspectives.

Script Identification in Medieval Latin Manuscripts Using Convolutional Neural Networks

Introduction

In paleography, scholars study the history of handwriting, a crucial aspect of book history and manuscript studies. Paleography has traditionally been dominated by expert-based approaches, driven by the opinions of a small group of highly trained individuals. These have acquired a set of expert skills through year-long training, e.g. the ability to date a handwriting or attribute it to specific individuals. This knowledge remains very hard to render explicit, in order to share it with others. Therefore, paleographers are increasingly interested in digital modelling techniques to enhance the creation and dissemination of paleographic knowledge (Stutzmann, 2015). An important task in paleography is the classification of script types, especially now that digital libraries (BVMM, Gallica, e-Codices, Manuscripta Mediaevalia, etc.) are amassing reproductions of medieval manuscripts, often with scarce metadata. Being able to recognize the script type of such historic artefacts is crucial to date, localize or (semi-)automatically transcribe them. This paper focuses on script identification for medieval Latin manuscripts (ca. 500 AD to 1600 AD) and demonstrates the feasibility of a fairly accurate, meaningful automated classification.

Medieval script classification was the focus of the recent CLaMM (Classification of Latin Medieval Manuscripts) competition. For this shared task, the organizers released a training data set of 2,000 photographic (greyscale, 300 dpi) reproductions of pages extracted from Latin manuscripts, which were classified into a 12 script type classes, including uncial, caroline, textualis and humanistic script, but also more difficult to delineate classes such as the cursiva or (semi)hybrida. The participating teams had to submit a standalone application which was able to classify unseen images and estimate the distance between them. The organizers would then apply the submissions to 1,000 resp. 2,000 test images (Stutzmann, 2016) and evaluate their performance using various evaluation schemes. Here, we discuss the *DeepScript* submission to the CLaMM competition. The competition's results have officially been released on 26 Oct. 2016. *DeepScript* was ranked first on task 2, i.e. the 'crisp' classification of mixed script images (Cloppet et al., 2016). As the ground truth and results were released too recently, we limit this abstract to a general discussion of the approach; the final version and presentation of this paper will be supplemented with additional information and test results.

The *DeepScript* submission builds upon recent advances in Computer Vision, where the use of so-called 'deep' neural networks has recently led to dramatic breakthroughs in the state of the art of image classification (LeCun et al., 2015). The kind of neural networks applied in Computer Vision are typically convolutional: they slide small 'filters' (feature detectors) across images to make the network robust to small translations of objects. The networks make use of many 'layers' of such feature detectors, where the output of one feature detector always feeds into the next one. The use of such a stack of layers is beneficial, because this 'deep architecture' allows algorithms to model features of an increasing complexity (Bengio et al., 2013): in the first layers of the network, very raw and primitive shapes are detected ('edges'); it is only at the higher layers in the networks that these primitive features are combined into more complex, abstract visual patterns (e.g. entire faces). These neural networks lie at the basis of e.g. modern face verification algorithms on social media websites such as *Facebook*.

Neural networks are composed of millions of parameters which have be optimized. For this, the available training data is split out in a set of training images and a smaller set of development images (respectively ca. 1,800 and 200 images): the former is used to optimize the parameters of the network during training, the latter is used to monitor the performance of the network. The use of development data is necessary to avoid 'overfitting': it is possible for a network to start 'memorizing' the training images, so that it produces perfect predictions for the training data, but is not able any more to generalize properly to new, unseen images. By using a development set, we can stop optimizing the network, if its predictions for the development data do not increase in quality anymore. Only at this stage, the algorithm is evaluated on the actual test images.

Modern neural networks are typically trained on hundred thousands of training images. In the field of Cultural Heritage data, a common challenge is that most data sets are much smaller, and CLaMM is no exception, so that the danger of overfitting is much larger. We therefore proceeded as follows: the generous resolution for each training image was downsized by one half. Next, we would select random square crops or patches from the image (150x150 pixels) and train the algorithms on batches of these crops. This approach is blunt, yet innovative, since we make no effort to extract more specific regions of interest from the images, such as individual lines, words or characters. To avoid overfitting, we also applied augmentation: each training crop would be 'distorted' through randomly varying the zoom level, rotation and translation. Introducing such noise in the input is a common strategy to combat overfitting. Below goes an example of such a set of augmented patches for a single manuscript page (Fig. 1).

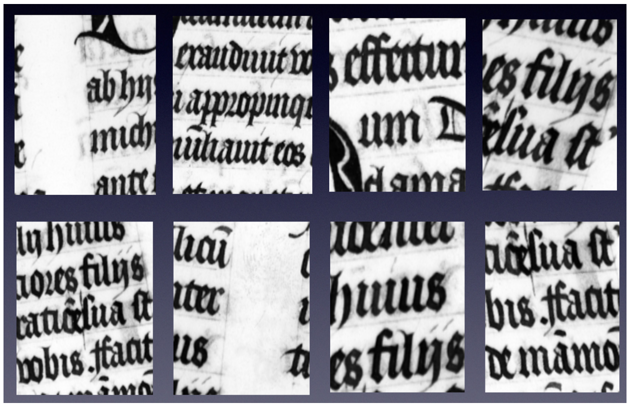

Fig. 1: Example of augmented crops for a single manuscript page.

After each epoch, we evaluated the performance of the current state of the network through inspecting the classification accuracy on the development images: we randomly selected 30 crops from each image (without augmentation), and calculated the average probability for each output class. The full image was assigned to the class with the highest average probability. The best validation accuracy which we achieved was 91.17%, using a network architecture of 14 layers, inspired by the famous Oxford VGG net (Simonyan et al., 2015). The manual classification of CLaMM images was based on morphological differences and allographs, as defined in standard works on Latin scripts such as (Bischoff, 1986; Derolez, 2003). The confusion matrices in Fig. 2-4 for the actual and the predicted classes in the development and test data illustrate that the confusions generally make sense from a paleographic point of view (the normal textualis letter is for instance often mistaken for the Southern or semi-textualis variant).

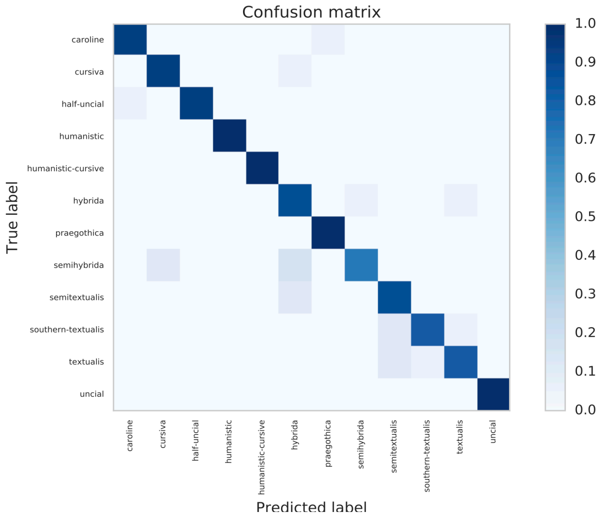

Fig. 2: Confusion matrix for the development data.

There exist interesting methods to visualize which patterns the trained network is sensitive to. Using the principle of gradient ascent, we start from a random noise image and feed it to one of the filters on the last convolutional layer: during 3,000 iterations we change the image so that it maximizes the activation of this particular filter. In Fig. 3, we show the 25 artificially generated images which yielded the strongest results; clearly, the network picks up relevant patterns. The third image from the left in the first line, for instance, clearly captures the presence of loops in the ascenders of individual characters (e.g. in the 'b' or 'h', which is crucial to differentiate between e.g. a textualis and a cursive letter). These visualizations directly tackle the issue of the computational 'black box' in the Digital Humanities, and espsecially Digital Palaeography (Hassner et al., 2013; Stutzmann et al., 2014). In our paper, we will offer further interpretations and visualizations of our model and confront these with the results from other participants in the CLaMM competition to offer new perspectives on the graphic definition of script classes in traditional paleography.

What Changed When Andy Weir's *The Martian* Got Edited?

Introduction

The Martian is a best-selling science fiction novel by Andy Weir that became a hit film in 2015. The novel exists in two versions, or variants: Weir self-published *The Martian* on his personal website in 2011 (hereafter, "*Martian1*") and began selling it on Amazon.com in 2012. Crown Publishing subsequently bought the rights, edited the book, and re-released it (hereafter, "*Martian2*").

The research presented here investigates what exactly changed when *The Martian* got edited. At first glance, the two versions appear essentially the same, with no major changes to plot, character, or structure. A closer look using a combination of quantitative and qualitative methods, however, reveals a number of noteworthy changes, as well as notable changes that result from thousands of seemingly minor copyedits.

Aims

The aim of our research is to identify what changed between the two variants of *The Martian* using a combination of close reading and digital methods, analyze why those changes are important, and propose a methodology for comparing self-published and later-edited novels, an increasingly common phenomenon. We hypothesize that the editing process of a leading publishing house results in a novel that is more "mainstream", i.e. socialised, domesticated, and appealing to a general audience. In order to test this hypothesis, we explore a range of aspects, including style, content, and character. Our research also aims to bring a critical perspective to the strengths and weaknesses of a variety of qualitative and technical methods in identifying the edits and assessing their importance.

Related Work

In addition to work in digital genetic criticism (e.g. van Hulle 2008), a small number of studies use digital methods to explore variants of contemporary fiction. Yufang Ho (2011) compared the 1966 and revised 1977 versions of John Fowles's novel *The Magus*, while Martin Paul Eve (2016) looked at differences in the US and UK versions of David Mitchell's *Cloud Atlas*. As both Ho and Eve use different methods from one another and from us, it appears that no standard method has emerged so far for this type of research.

Data

The data used for this research is primarily two plain text files of the variants of *The Martian*. *Martian1* was obtained in PDF format from Andy Weir's website. *Martian2* was obtained by scanning a print copy, performing OCR with manual corrections. We consider this our best option given the legal issues regarding text protected by copyright.

Methods and Results

Basic collation

We used the Wdiff frontend to the "diff" algorithm (Hunt & McIlroy 1975) to produce a collated version of *Martian1* and *Martian2* and assess the number and extent of the edits. We then used bespoke Python scripts to classify the edits identified by Wdiff.

We found a total of 5146 edits were made to the novel. While 92% of the 101,000 words in *Martian1* remain unchanged in *Martian2*, the remaining 8% of the words undergo some type of edit, whether they are deleted or modified (Figure 1). The sheer number of edits calls for automatic means to classify them and detect any patterns.

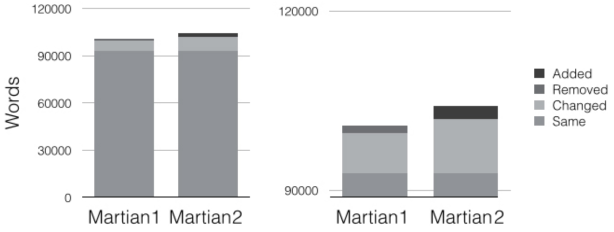

Figure 1: Visualization of edits to The Martian as grouped by Wdiff.

Automatic Classification of Edits

Edits were automatically classified into two broad categories: script-detectable copyedits, and all other edits. Script-detectable copyedits includes changes in capitalization, whitespace, hyphenation, spelling of numbers, abbreviations, or combinations thereof (Figure 2). All other edits were classified as insertion, deletion, expansion or condensation and as "minor" or "major", depending on the Levenshtein distance (Figure 3). Of the 5146 edits, 2863 (or 55%) were script-detectable copyedits, while 2283 (or 45%) comprised the rest. The code used as well as the collation data obtained are available on GitHub.

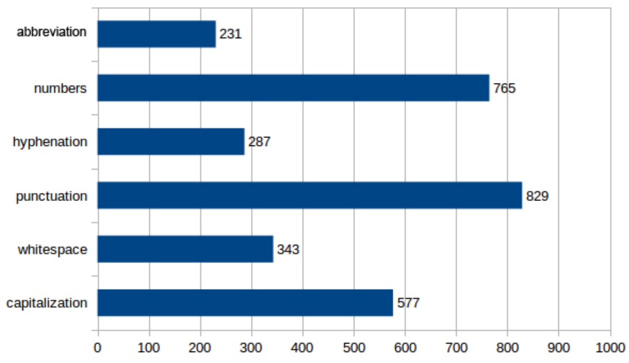

Figure 2: Script-identifiable copyedits to *The Martian.*

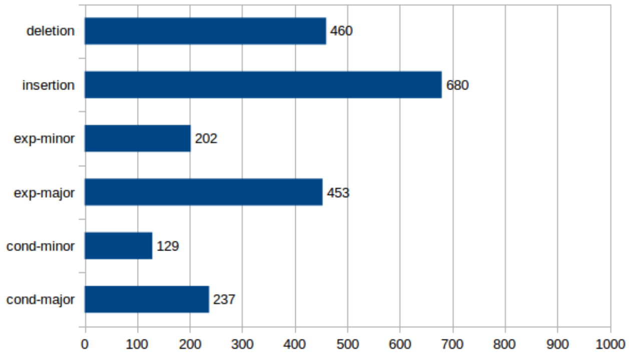

Figure 3: All other edits to *The Martian.*

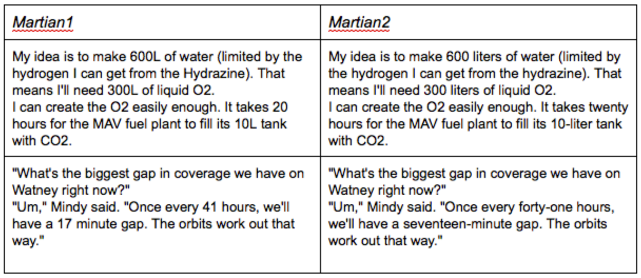
Cumulative Effect of the Script-Identifiable Copyedits

Taken together, the 2863 script-identifiable copyedits have substantial effects upon the text. Weir's many misspellings and misuse of hyphens and capitalization are corrected. Numbers in *Martian1* are overwhelmingly written numerically, and 765 of these become words in *Martian2*, e.g. "8" becomes "eight". We found 231 instances of edits involving abbreviations, e.g. "L" becomes "liters".

The copyedits work together in different ways when they appear in protagonist Mark Watney's narration or in sections written in the third person (Figure 4). When Watney narrates, the hundreds of misspellings, numerals, and scientific abbreviations in *Martian1* support the fiction that he is a scientist working in extreme conditions. *Martian2* increases readability but eliminates the stylistic realism of Watney's text. When Weir uses, for instance, numerals in the dialogue of other characters, the effect can be jarring. *Martian2* corrects this for the better.



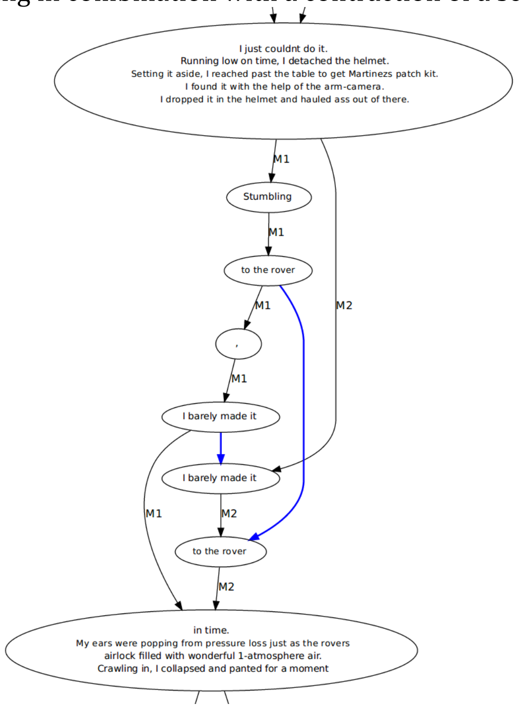
Martian1	*Martian2*
My idea is to make 600L of water (limited by the hydrogen I can get from the Hydrazine). That means I'll need 300L of liquid O2. I can create the O2 easily enough. It takes 20 hours for the MAV fuel plant to fill its 10L tank with CO2.	My idea is to make 600 liters of water (limited by the hydrogen I can get from the hydrazine). That means I'll need 300 liters of liquid O2. I can create the O2 easily enough. It takes twenty hours for the MAV fuel plant to fill its 10-liter tank with CO2.
"What's the biggest gap in coverage we have on Watney right now?" "Um," Mindy said. "Once every 41 hours, we'll have a 17 minute gap. The orbits work out that way."	"What's the biggest gap in coverage we have on Watney right now?" "Um," Mindy said. "Once every forty-one hours, we'll have a seventeen-minute gap. The orbits work out that way."

Figure 4: Edits to numerals and scientific abbreviations in Watney's narration (top) and third-person character dialogue (bottom).

Detecting transpositions with CollateX

Wdiff does not detect transpositions, or text that has been moved to a different location in the novel. Using CollateX (Dekker & Middell 2011) as described in Schöch (2016) revealed a total of 126 transpositions. Twenty-eight (or 22%) involve punctuation and should be considered artefacts of the method; 43 (or 34%) represent transpositions of a single word, showing stylistic preferences on the word-order level; 55 (or 44%) concern multi-word expressions which change the overall construction of a sentence or paragraph more substantially.

Figure 5 shows a relatively minor transposition appearing in combination with a contraction of a sentence.



I just couldnt do it.
Running low on time, I detached the helmet.
Setting it aside, I reached past the table to get Martinezs patch kit.
I found it with the help of the arm-camera.
I dropped it in the helmet and hauled ass out of there.

in time.
My ears were popping from pressure loss just as the rovers
airlock filled with wonderful 1-atmosphere air.
Crawling in, I collapsed and panted for a moment

Figure 5: An example of a transposition identified by CollateX.

We conclude that, quantitatively and qualitatively, transpositions were not a major part of the edit to *The Martian*. However, future work could apply the same method to other, comparable variants of novels to gain better reference points.

Close Reading of Other Edits

When we grouped the other edits, placed them into a spreadsheet, and manually inspected them, a number of thematic and stylistic shifts between *Martian1* and *Martian2* became apparent.

Profanity is a key stylistic feature of *The Martian* that is substantially cut and softened by the edit. Words like “fuck” and “shit” are substantially reduced (by about 33% and 15%, respectively), while numerous other words and phrases are softened with “lesser” profanity or simple non-profanity (e.g. “the shit hits the fan” becomes “all hell breaks loose”). Figure 6 shows a selection of these edits. Similarly, crude and sophomoric humor is cut in key instances.

The plot of *The Martian* revolves around solving one problem after another to rescue an astronaut, Mark Watney, stranded on Mars, while relatively little text is devoted to Watney’s emotions or inner world. In *Martian2*, however, Watney expresses significantly more emotion: he misses his family and friends more and expresses despair, loneliness, and introspection more often.

Figure 6: examples of toned-down profanity in the editing of The Martian

Additionally, *Martian1* contains an epilogue that is completely cut in the edit. It portrays Watney, back on Earth, being openly and profanely rude to a young fan. In *Martian2*, meanwhile, text is added to have Watney express gracious appreciation for all the parties involved in his rescue and a widespread faith in human nature. The edit therefore alters the tone of the ending substantially.

We believe that all of these changes, analyzed together with close reading, serve to align Watney’s character with our overall hypothesized goal of the edit: to make Watney more “relatable,” “nice,” and “human,” and thus to appeal to a wider audience.

Edits Over the Course of the Novel

Patterns in the edits related to textual progression are revealed by measuring the absolute Levenshtein distance of the script-identifiable copyedits and other edits line by line (Levenshtein distance is a metric for measuring the difference between two sequences, see Navarro 2001).

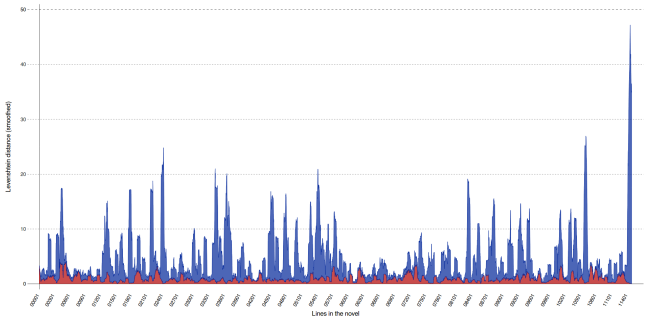

Figure 7: Sum of absolute Levenshtein distance per line over textual progression (script-identifiable copyedits in red, other edits in blue).

Figure 7 shows the sum of the absolute Levenshtein distances for each line of the novel (with Savitzky-Golay smoothing applied). The graph shows the substantial modifications to the ending of the novel, but also a large number of locations with smaller but nonetheless above-average modifications.

Conclusion and Further Research

We have identified and analyzed a number of key features that emerged from the editing of *The Martian*, notably on the level of style and character, which combine to make the novel more appealing to a wider audience.

Ongoing research into *The Martian* concerns the relative frequency and function of parts of speech, quantifying the amount of syntactic change, and the legal issues affecting the obtaining and processing of the texts. We hope to present these additional findings in the near future.

As for our typology of edits, an established methodology for classifying edits in the companion fields of textual analysis and scholarly editing is the distinction between the “accidentals” and “substantives” used by the Greg-Bowers tradition and included in the MLA Committee on Scholarly Editions’ *Guidelines for Editors of Scholarly Editions* (Modern Language Association, 2011). Scholars are not unanimous, however, in supporting this. G. Thomas Tanselle, for instance, found these terms “misleading and often untenable in their implication of a firm distinction in all cases” (Greetham 1992, pp.335-336). Further, there appears to be no widely-applicable typology of edits in digital scholarly editing and collation, with different materials calling for different typologies (see TEI-L 2016).

Our typology of edits departs from previously proposed ones by focusing entirely on types which can be identified automatically, based on surface features. While limited in scope and excluding any semantic criteria, our typology may serve as a first approach to the edits of any text and allow quantitative comparison of some key phenomena. We believe that our method could be applied to other variants of fiction — by itself or incorporated alongside another taxonomy, including accidentals/substantives — particularly to novels which begin as self-published works but are later edited and re-released, an increasingly important phenomenon in contemporary fiction.

Prototypical Emotion Developments in Literary Genres

Introduction

Storytelling is a central form of human artistic expression. An ingredient of the appeal of stories is their emotional content. Readers of literature form explicit mental representations of fictional characters’ emotional states (Gernsbacher, Goldsmith, and Robertson, 1992; Vega, 1996). Even more, a gripping “[...] literary work produces a complex emotional experience in the reader. This experience is inseparable from the depictive content of the narrative” (Hogan, 2011). This raises the question of the relationship between the narrative and emotional levels in literature. We explore how computational emotion analysis can contribute to the characterization of story genres, which are difficult to define and for which various criteria have been proposed, including stylistic ones (Biber and Conrad, 2009) and narratological ones (Chatman, 1978).

Our hypothesis is that genres can be linked to the development of predominant emotions over the course of the text. To test this, we present a computational model of multi-label emotion analysis of literary genres and apply it to a set of English literary works from the Project Gutenberg for five genres, namely adventure, romance, mystery, science fiction, and humorous fiction. We identify prototypical shapes for each genre and show that this analysis produces results, which can find a place in the computational analysis of literary genres and extend existing stylometric approaches.

Cuddon (2012) defines adventure as “a form of fiction [...] in which the hero conventionally undergoes a series of testing and episodic adventures” and mystery as a narrative involving the “detection of crime, with the motives, actions, arraignment, judgement and punishment of a criminal”. Baldick (2015) defined Romance as narratives with "improbable adventures of idealized characters”. Today, however, the term covers many forms of fiction, including love stories. We use the term romance as a literary genre in this broader sense. Regarding science fiction stories, it is generally agreed that they are “[...] about an amazing variety of things, topics, ideas. They include trips to other worlds, quests, the exploration of space...” (Cuddon, 2012). Humorous fiction is comical literature “written chiefly to amuse its audience" (Cuddon, 2012).

Methods

We calculate emotion scores for eight basic emotions, namely joy, sadness, trust, disgust, fear, anger, surprise, and anticipation (Plutchik, 2001). We use the NRC Emotion Lexicon (Mohammad and Turney, 2013). Since the data in Project Gutenberg is diachronic, this method of emotion recognition might not be appropriate for older texts and, in general, may suffer from low recall. However, it can be considered a high-precision approach suitable for our purpose.

To obtain an emotion analysis for a story, we start by computing emotion scores for spans of text (Klinger, Suliya, and Reiter, 2016). Formally, we compute the score es(e, S) for an emotion e and a span of tokens S=<tn,...,tm> as

$$es(e,S) = \frac{1}{|D_e|} \sum_{t_i \in S} 1_{t_i \in D_e}$$

where De is a dictionary containing words associated with emotion e and $1_{t \in D}$ is 1 if t ∈ D and 0 otherwise. We do this for each of our eight emotions, obtaining an eight dimensional “emotion vector” for each span. We analyzed the stability of our results across different settings and found that different dictionaries affect the actual values but not the relation between different time steps. These scores are not probabilities, but could be transformed if needed.

To observe development over time, we could use sliding windows; however, continuous time series are notoriously difficult to interpret. Therefore, we adopt a simpler scheme inspired by the five-act theory of dramatic acts (Freytag, 1863), according to which dramas are divided into five acts: exposition, rising action, climax, falling action, and denouement. We consequently divide each text into five successive, equal-sized spans (since different texts have different length, the size of acts varies between texts) that we assume to correspond roughly to dramatic acts in Freytag’s theory, with exposition at position 1 and denouement at position 5, and compute an eight-element emotion vector for each Act.

Experimental Evaluation

We now demonstrate how this emotion aggregation into five acts can contribute to the understanding of different literary genres.

Data

We collect 2113 books from Project Gutenberg that belong to five genres found in the Brown corpus (Francis and Kucera, 1979), namely adventure (585 books), romance (383 books), mystery (380 books), science fiction (562 books), and humorous fiction (203 books). The corpus is available from the authors upon request.

The selection is based on the Library of Congress Subject Headings in the metadata. We select all books that contain the word “Fiction” in combination with one of the following labels: “Adventure stories”, “Love stories”, “Romantic fiction”, “Detective and mystery stories”, “Science fiction” or “Humor”. Furthermore, we reject books with the following labels: “Short stories”, “Complete works”, “Volume”, “Chapter”, “Collection”, “Part”. This constraint is aimed at excluding files which contain partial or multiple works.

Qualitative analysis

Each plot in Figure 1 depicts the act-by-act development for one emotion with their emotion score es(e,S). Since we interpret shapes rather than values, we omit the legend. The average over all books is shown in a dark-colored line. The area around that line corresponds to confidence intervals at a 95% confidence level.

For sadness, anger, fear, and disgust, all five genres show a close correspondence, namely a consistent increase of the emotion from Act 1 through Act 5 – corresponding to gripping narratives. Mystery and science fiction lack the drop in anger and tend to end with higher levels of this emotion. Joy is inverse to these emotions, showing a decreasing tendency from Act 1 to Act 5 for all genres with exception of humorous fiction that shows a plateau between Acts 1 and 4.

In adventures, all emotions increase in the first half of the books, but drop sharply between Act 4 and Act 5. This is consistent with Whetter (2008), according to whom adventures are marked by a late drop in emotional tension when the hero’s misfortunes come to an end. The only exception is trust that shows increase towards the end for all genres, which is especially noticeable in adventures. A potential reason is that prototypical adventure novels are ‘upbeat’ in that they cultivate virtues such as courage and loyalty (Baldick, 2015, p. 5) and depict heroes that do not lose trust even amid unexpected dangers.

The results for anticipation and surprise show less coherent tendencies which we find difficult to interpret. These two emotions appear less constitutive to the narrative structure of genres, at least those that we currently consider: anticipation and surprise can occur under (almost) any circumstances. Mystery fiction has a slightly different pattern, where anticipation exhibits steady increase from Acts 1 to 4 and its peak coincides with the peak for surprise at Act 4.

Quantitative analysis

We analyze the genre-specific time course of emotions quantitatively by computing associations between genres and the Act in which an emotion “peaks” in a story. We define a random variable vie for an emotion peak as vie=1 iff the highest value of emotion e is in Act i. The association between each genre and emotion peaks vie follows point-wise mutual information (Church and Hanks, 1990),

$$PMI(g, v_e^j) = \log \frac{p(v_e^j, g)}{p(g)p(v_e^j)},$$

where probabilities are computed as relative frequencies over the dataset.

Figure 2 gives insight into the genre-specific emotion patterns. For instance, disgust is characteristic of Act 4 for all genres. The only exception is science fiction that does not list disgust or surprise among the top 10 features. Trust is important at the beginning and in the end of adventures and science fiction, but is missing in mystery. Similarly, romance fiction is not characterized by anticipation among top-ranked features, corresponding to its “anticipation” curve that decreases monotone from beginning to end. Interestingly, humor is the only genre that does not contain joy among the top 10 features.

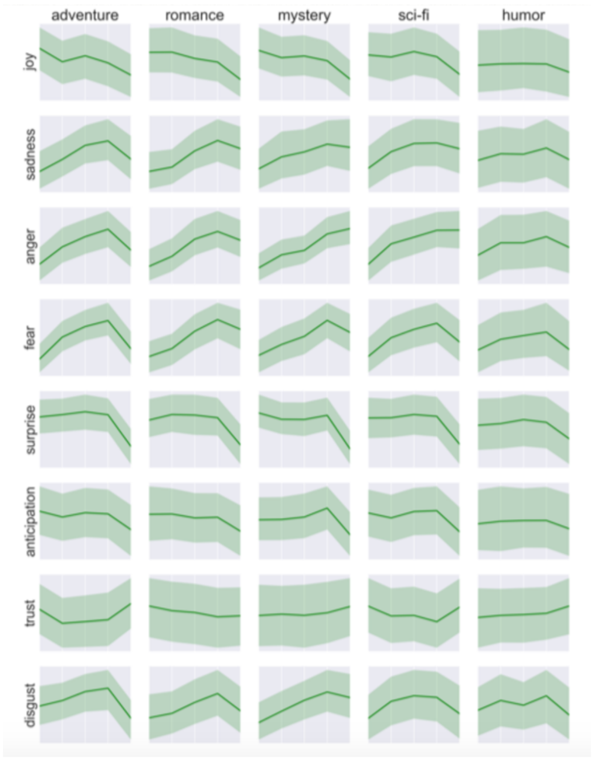

Figure 1: Genre-specific emotion curves

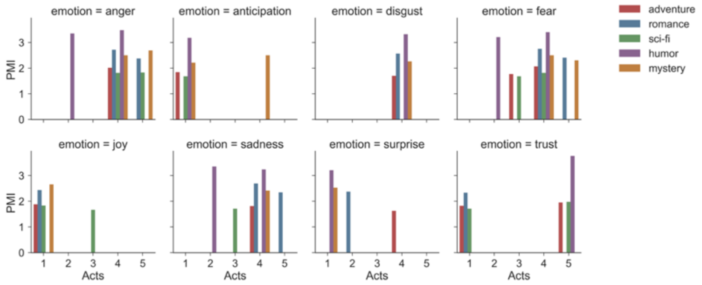

Figure 2: Top 10 PMI features for each genre

Related work

Sentiment and emotion in fiction have been previously addressed computationally by Mohammad (2012), Nalisnick and Baird (2013), Heuser, Moretti, and Steiner (2016), among others. Samothrakis and Fasli (2015) is the only work we are aware of which discusses emotions in context of genres.

The study most related to ours is Reagan et al. (2016). They propose a pipeline that tracks emotions in text. Their main claim is that stories typically follow one out of six “emotional arcs” regarding happiness.

Conclusion, discussion and future work

We investigated the relationship between emotional development in literature and genre and observe differences among emotions. The genre of adventure stands out, especially concerning the end of the story arc. Our results can provide a novel starting point for characterizing similarities and differences within and between literary genres.

Our observations require further investigation regarding the underlying factors. For instance, it might be argued that the pattern for mystery stories is dominated by the subgenre of crime fiction. Future work will combine our distant reading approach with close and scalable reading. Furthermore, to improve emotion recognition, we plan to use distributional methods for expanding the existing lexical resources and adapting them to texts from different historical periods (cf. Buechel, Hellrich, and Hahn, 2016).

Measuring completeness as metadata quality metric in Europeana

Péter Király
pkiraly@gwdg.de
Gesellschaft für wissenschaftliche Datenverarbeitung mbH
Göttingen
Germany

Introduction

The functionalities of an aggregated metadata collection are dependent on the quality of metadata records. Some examples from Europeana, the European digital library, to display the importance of metadata: (a) Several thousands records have the title „Photo" without further descriptions; how can a user find these objects?, (b) Several data providers listed in the „Institution" facet under multiple different names, should we expect that the user will select all name forms of an organization?, (c) Without formalized date value, we are not able to use the functionality of interactive date range selectors. The question is how can we determine which records should be improved, and which are good enough? The manual evaluation of each record is not affordable. This paper proposes a methodology and a software package, which can be used in Europeana and elsewhere in the domain of cultural heritage.

Background and foundations

Europeana collects and presents cultural heritage metadata records. The database contains more than 53 million records from more than 3200 institutions (figures extracted from the Europeana Search API) in the Europeana Data Model (EDM) schema. The organizations send their data in EDM or in another metadata standard. Due to the variety of original data formats, cataloging rules, languages and vocabularies, there are big differences in the quality of the individual records, which heavily affects the functionalities of Europeana's services.

In 2015 a Europeana task force investigating the problem of metadata quality published a report (Dangerfield et al., 2015), however – as stated – „there was not enough scope … to investigate … metrics for metadata quality ….” In 2016 a wider Data Quality Committee was founded. The current research is conducted in collaboration with it, having the purpose of finding methods, metrics and building an open source tool (see also, the project’s Github page) to measure metadata quality.

State of the art

The computational methods of metadata quality assessment emerged in the last decade in the domain (Bruce and Hillmann, 2004, Stvilia et al., 2007, Ochoa and Duval, 2009, Harper, 2016). Papers defined quality metrics and suggested computational implementations. They however mostly analyzed smaller volumes of records, metadata schemas which are less complex than EDM, and usually applied methods to more homogeneous data sets. The novelty of this research is that it increases the volume of records, introduces data visualizations, and provides open source implementation to use in other collections.

Methodology

For every record, features were extracted or deducted which somehow related to the quality of the records. The main feature groups are:

- **simple completeness** – ratio of filled fields,
- **completeness of sub-dimensions** – fields groups support particular functions, such as searching, or accessibility,
- **existence and cardinality of fields** – which fields are filled and how intensively.

The measurements happen on three levels: on individual records, on subsets (e.g. records of a data provider), and on the whole dataset. On second and third level we calculate aggregated metrics; the completeness of structural entities (such as the main descriptive part and the contextual entities – agent, concept, place, timespan – connecting the description to linked open data vocabularies).

The final completeness score is the combination of two approaches. In the first one the weighting reflects sub-dimensions. In the second one, the main factor is the normalized version of cardinality to prevent biasing effect of extreme values.

The tool – built on big data analytics software Apache Spark, the R statistical software and has a web front-end – is modular. There is a schema-independent core library and schema specific extensions. It is designed to be used in continuous integration for metadata quality assessment.

Results

Comparison of the scores of the field importance and field cardinality approaches shows that they give different results (however they correlate by the Pearson’s coefficient of 0.52.). Because of the nature of calculation the compound score is quite close to the first approach: the functionality based scores lie in the range of 0.186 and 0.76 and cardinality scores are in the range of 0.031 and 0.335, and it has smaller effect on the final score.

There are data providers, where all (in some cases more than ten thousand) records get the same scores: they have uniform structure. The field-level analysis shows (what one simple score is not able to testify) that in these collections all the records has the very same (Dublin Core based) field set. On the other end there are collections where both scores diverge a lot. For example in the identifying sub-dimension a data provider has five distinct values (from 0.4 to 0.8) almost evenly distributed while one of the best collection (of the category) is almost homogeneous: 99,7% or the records have the same value: 0.9 (even the rest 0.3% has 0.8). It means that in the records of the first dataset the corresponding fields (dc:title, dcterms:alternative, dc:description, dc:type, dc:identifier, dc:date, dcterms:created and dcterms:issued in the ore:Proxy part and edm:provider and edm:dataProvider in the ore:Aggregation) are frequently not available, while they are almost always there in the second. The tool provides different graphs and tables to visualize the distribution of the scores.

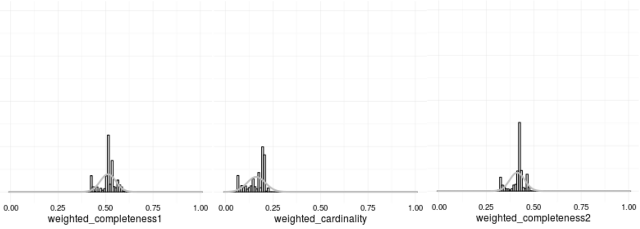

Figure 1. Distribution of completeness scores in a dataset. We can see the differences between the functionality based (left),the cardinality based (center) and the combined method (right).

From the distribution of the fields the first conclusion is that lots of records miss contextual entities, and only a couple of data provider has 100% coverage (6% of the records has *agent*, 28% has *place*, 32% has *timespan* and 40% has *concept* entities). Only the mandatory technical elements appear in every records. There are fields, which are defined in the schema, but not filled in the records and there are overused fields – e. g. *dc:description* is frequently used instead of more specific fields (such as table of contents, subject related fields or alternative title).

Users can check all the features on top, collection, and records level on the web interface. Data providers get a clear view of their data, and based on this analysis they can design a data cleaning or data improvement plan.

Europeana is working on its new ingestion system which integrates the tool. When a new record-set will arrive, the measuring will run automatically, and the Ingestion Officer can check the quality report.

Further work

We will examine other metrics (e.g. multilinguality, accuracy, information content, timeliness), and check known metadata anti-patterns. We plan to compare the scores with experts' evaluation and with usage data and to implement related W3C standards: Shapes Constraint Language (Knublauch and Kontokostas, 2016), and Data Quality Vocabulary (Albertoni and Isaac, 2016).

Conclusion

In the research we re-thought the relationship between functionality and the metadata schema, implemented a framework which proved to be successful in measuring structural features which correlate with metadata issues, and we were able to select low and high quality records. We remarkably extended the volume of the analyzed records by introducing big data tools, which were not mentioned previously in the literature.

I showed my research in case of a particular dataset and data schema but the method I follow based on generalized algorithms, so it is applicable to other data schema. Several DH researches based on schema defined cultural databases, and in those cases the research process could be improving by finding the weak points of the sources.

Acknowledgements

I would like to thank all of the members of the Europeana Data Quality Committee.

A Pale Reflection of the Violent Truth? Practice and Pedagogy with a Digital Geography of American Lynching

Seth Kotch
sethk@unc.edu
UNC Chapel Hill, United States of America

Elijah Gaddis
ejgaddis@live.unc.edu
UNC Chapel Hill, United States of America

We propose a discussion of the pedagogical process and representational implications of our digital project, *The Red Record*. *The Red Record* is an open-ended, ongoing project created using DH Press that situates historic American lynchings, starting with those that took place in North Carolina, on a Cartesian map. In its current state the project offers primary source documentation and scholar-produced context for each of the 112 lynching events, which took the lives of 147 people in the state between 1865 and 1941. The initial project was undertaken by a seminar of first year students at the University of North Carolina, and subsequently amended with the research of two additional undergraduate classes. In the session proposed here, we detail the process of research and the intertwined workflow that simultaneously teaches students primary research skills and forces them to confront the legacies of racial violence inherent in the landscapes they live in. We suggest that the pedagogical model of this project has broader implications for the ways that digital representations might seek to engage diverse populations in understanding and contributing to the knowledge of the places they are from. In the papers here, we consider both the implications of digital representations of lynching, and the possibilities and practical obstacles in extending this project through student and community crowdsourcing.

Until recently, North Carolina has enjoyed a reputation as a less objectionable southern state, whether as a "vale of humility" between the less commendable Virginia and South Carolina, or as a "business progressive" southern state, concerned enough about outside investment to control its citizens' worst impulses. The problem of lynching, widely studied in states such as Georgia and Virginia, has received less attention from North Carolina's scholars: the only monograph on the subject is a summary-study our research found to contain a number of errors. Visual scholarship on the subject is limited. In 2000, *Without Sanctuary*, a gruesome collection of lynching postcards, opened in New York and was soon followed by a website which still exists but which shows its age. *Without Sanctuary* was and is an important project, one that shocked viewers as to the extent of historical violence. Yet today, as we regularly witness violence against persons of color on social media or television news, we must wonder about troubling side effects of *Without Sanctuary*: that in presenting lynchings as sepia-toned horrors of the past, it appeared to relegate such violence to history and allow for a self-satisfied reassurance that this time had passed.

Such is the challenge for any project addressing historical trauma. Adding to this concern are questions of representation. In uncritically presenting images of lynchings, *Without Sanctuary* risked reproducing the work of those postcards, which traveled the country presenting damaged black bodies that titillated as much as it horrified, and even in their extremity regularized and commodified anti-Black violence. We know that lynchings themselves echoed across generations in Black communities (Wolf, 1992) did *Without Sanctuary* address that trauma or amplify it? Do the victims of lynchings have, in a sense, the right to be forgotten? (Causey, 2015) In pursuing Locating Lynching, we remained aware of these risks and encountered still more: how to choose visual anchors for our display, whether or not to publish images of trauma, how to share accounts of lynchings from the white and Black presses without false equivalence, what kinds of information to include about persons who do not deserve to be remembered only as victims. Our panel will address these issues in detail, share our solutions, and explain our next steps as we continue to work.

A key element of our project and our panel is pedagogy, both in terms of engaging undergraduate students with digital, primary-source research and in terms of engaging them with a traumatic subject. It is the rare undergraduate student, particularly in a seminar designed for first-year students, who is well-equipped to conduct original research. But with the recent digitization of hundreds of thousands of pages of small-town newspapers, of censuses from the 19th and early 20th centuries, and of city directories and historic maps, the hidden histories of lynchings, their victims, and their perpetrators have never been more visible. As historians, we can and have learned stories from the darkened margins: We have learned the story a young man who escaped a lynching attempt and fled the state, ending up, married and with a son, as a doorman in the United Nations building in Manhattan. We have learned the names of the white men who kidnapped from jail an African American man jailed on a rape accusation and hanged him. We know these people's addresses, their occupations, the names of their parents and children. In both these marginal stories, and in the aggregating potential of digital visualizations, we can tell some small part of the abbreviated life stories of these people, albeit in the context of their deaths. Teaching undergraduate students the process whereby they can make these discoveries – as detailed in our nine-page research guide – can be transformative. We ask our students, who are awash in digital representation and misrepresentation, to carefully consider their choices in saving, commenting on, and presenting past identities.

Executive summary

In the course of the digitization of information, research data management has become one of the most important new areas of research. Universities have to prepare themselves to provide their academics and researchers with the necessary infrastructures and services. To identify the current demands regarding the handling of research data at the Faculty of Arts and Humanities of the University of Cologne, the Data Center for the Humanities conducted an online survey in 2016 in cooperation with the Office of the Dean of the Faculty of Arts and Humanities as well as the University and Library of Cologne. The enquiry aimed to characterize the present situation and to obtain information on the demands in the sectors research data management and consultation services. Our talk will show ongoing developments at the international and national level in research data management, present the results of the survey and discuss potential conclusions.

Relevance

One of the most important fields of action in research which is developing along with the digitalization of information is research data management (RDM). The universities face the challenge of offering their researchers adequate structures and services. The managing board of the

German universities organized in the German Rector's Conference (HRK) has identified this as a key task (HRK 2014 and 2015). Moreover, in the recently published position paper called "Performance by diversity" the German Council for Scientific Information Infrastructures (RfII) makes a series of recommendations concerning how research data should be managed in the future (RfII 2016). The RfII was tasked by Germany's Joint Science Conference (GWK) with formulating broad-based recommendations for the science system in Germany as a whole. In addition, according to estimates by the German Research Foundation (DFG), up to 90% of the digital generated research data and results are still getting lost (Winkler-Nees 2011, p. 5) or "disappear in the drawer" (Kramer 2014) shortly after completion of research projects and are therefore not available for further use and reuse.

Method

As a structured way to gain information, we decided to follow the six stages process recommended for survey research (Müller et al. 2014). In addition, the survey is based on the relevant articles published in the handbook "Methods of Library and Information Science" by Umlauf, Fühles-Ubach & Seadle (Umlauf et al. 2013). The six steps are briefly explained below.

The Internet survey, the online questionnaire as well as the detailed report are published on the DCH-Website (see also Kronenwett 2017).

Research goals and constructs

The goal of the survey is to contribute to the conceptual development of the Data Center for the Humanities (DCH), which was founded as a central infrastructure service institution by the faculty dealing with humanities research data in 2013. In practice, the enquiry aims to characterize the present situation and to obtain information on the demands in the sectors RDM and consultation services offered by the DCH in cooperation with the University and City Library of Cologne (USB), one of the local partners of the DCH. Another goal was the comparability with other surveys conducted in the field.

Population and sampling

Because RDM should be handled in a way specific to each discipline (Sahle et al. 2013), the survey targeted only researchers at the Faculty of Arts and Humanities of the University of Cologne - one of the largest humanities faculties in Europe. The survey's population is limited to the academic staff of the Faculty of Arts and Humanities of the University of Cologne. In particular, the survey focused on researchers who are responsible for data-driven research projects.

Questionnaire design and biases

Firstly, with regards to content, conceptual and methodical design of the survey, Internet surveys and online questionnaires on research data at national and international scientific institutions and research institutes were analyzed so far available (the website "forschungsdaten.org" offers an overview regarding national and international surveys on research data). Secondly, the questionnaire design was tailored and adapted to suit the unique circumstances which can be found at the Faculty of Arts and Humanities (DCH 2016, CCeH 2016). Finally, the results of a series of expert interviews carried out by the DCH with researchers at the Faculty were taken into account (Blumtritt 2016, p. 16). The questionnaire addresses five issues, namely (1) research data, (2) use of data archives, (3) support for research data, (4) discipline and position, (5) interest.

Review and survey pretesting

After a review of the questionnaire with stakeholders, such as the dean’s office, the library and the data protection officer, a test link was sent to 20 potential subjects. This included representatives of all subject groups of the Faculty of Arts and Humanities (Faculty of Arts and Humanities 2016) as well as external experts (mostly sociologists and colleagues with RDM-background). After several feedback loops, the questionnaire was further modified and optimized.

Implementation and launch

The questionnaire was compiled using Kronenwett & Adolphs online survey tool (Kronenwett & Adolphs 2017). It was put online from 2016-05-30 to 2016-06-12 (2 weeks). Depending on individual answers the questionnaire contained up to 24 questions.

Data analysis and reporting

The questionnaire was completely answered by 136 participants (out of 191 persons who started the survey) which is 71.20% completion rate. The following selection of data analysis and reporting takes into account only these participants (n=136).

Results

Our objective in the compilation of the questionnaire was to answer the following questions:

1. What research data are available?
2. What is the need for research data?
3. What support do the members of the Faculty of Arts and Humanities want from the DCH?

Regarding the first question, sustainability and data volume were important to us. As far as sustainability is concerned, the majority of respondents are storing their research data on their local computers: 70% work computer, 70% private computer, multiple responses were possible (see fig. 1). Only 14% are storing their data in a data archive, a number that is also reflected in other questions like how many participants can imagine their data being stored in a data archive.

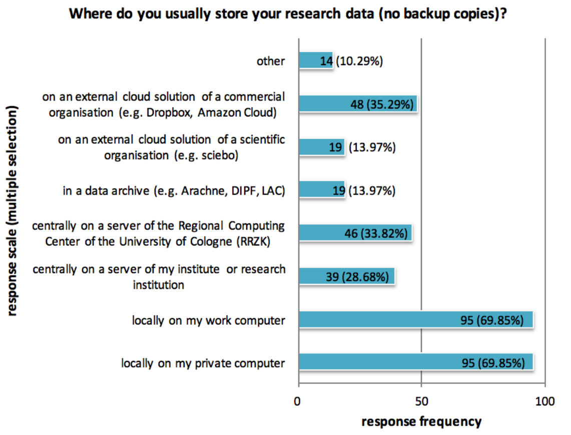

Figure 1. Storage places (n=136)

Regarding sustainability standards the given answers are fatal results since structured access and retrievability of research data are only ensured in professional data archives. Cloud solutions are also quite popular (35% use by commercial vendors and 14% of scientific vendors) because they ensure overall data access and data share. But regarding aspects like data plausibility, traceability or even long-term preservation they are totally unsuitable.

This result could be explained by the fact that the participants do not reflect their approach to sustainability and traceability. The vast majority of the respondent's self-assessment regarding their own skills in RDM is rated to be average or even less (71%) (see figure 2).

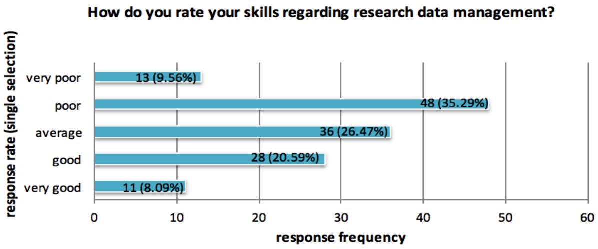

Figure 2. Self-assessment RDM-skills (n=136)

Sustainability is seen as a problem. 66% of the participants state that data could be lost when there is no one to be responsible for the website. 60% fear problems with data conversion. There is some sensibility towards the issues of finding the data (45%) and documentation of the data (41%). Figure 3 shows all answers concerning problems the participants see with preserving research data. Interesting is that both privacy and data theft are the concerns voiced the least frequent (11% each), despite the fact that we encounter these concerns frequently in our consulting practice. But this could be an anomaly due to us asking from the user perspective rather than the data giving perspective which is more typical to our consulting.

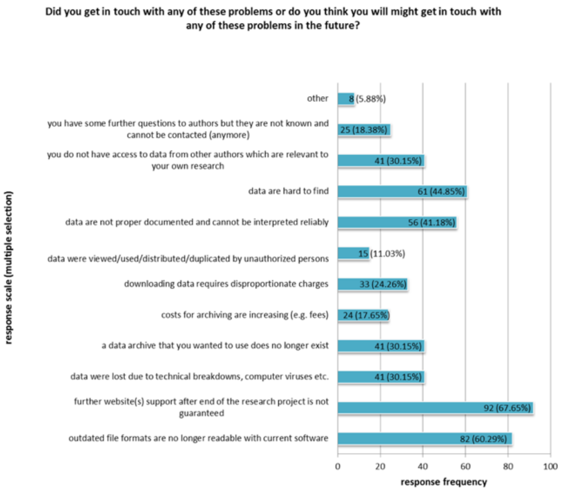

Figure 3. Past and future problems (n=136)

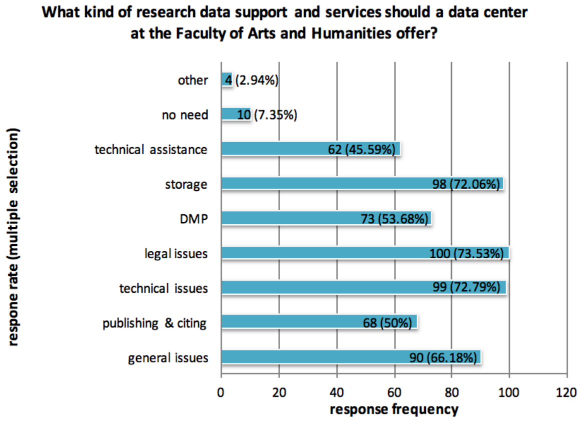

Figure 4. Support and services needed (n=136)

In an effort to improve our services towards the faculty, we also asked which services should be provided by the DCH. Here legal and technical issues featured prominently (74% and 73% respectively; also cf. Fig. 4). Requests for storage (72%) and consultation (66%) on general issues are also in high demand.

Conclusion and outlook

As a result of the survey, we propose the following recommendations for action for the University of Cologne on the one hand and for the DCH on the other hand. Together with the local library (USB), the DCH now offers legal counseling on the subject of research data with a specialized lawyer. We are currently planning a project for improving the sustainability of living software systems, since the survey showed that this is an eminent problem in our faculty. Based on the projected storage space from the survey, we have negotiated with the computing center to provide that space centrally for all the members of our faculty.

In our talk, we will give more details on the study and its results and will also compare it to other surveys conducted internationally. We feel that surveys of this nature are an important tool to shape strategic decisions made in institutions concerned with research data.

Introduction

La recherche en sciences humaines et sociales vit un tournant numérique qui provoque une évolution sensible des pratiques de recherche.

Aujourd'hui, les chercheurs produisent d'importants volumes de données numériques et utilisent des outils spécialisés pour y accéder, les manipuler, les visualiser et les diffuser. Cela nécessite d'associer ces grands volumes de données à des moyens technologiques qui se doivent d'être stables et conséquents. La maitrise de ce nouvel environnement doit s'appuyer sur le développement de compétences diversifiées et en constante évolution.

La mise en œuvre de cet écosystème ne peut plus être réalisée avec les moyens dont disposent les chercheurs individuellement ou même à l'échelle d'une équipe de recherche. Une infrastructure, au sens élargi du terme, est nécessaire pour être à même de fournir et mutualiser différents services et d'accompagner les équipes de recherche tout au long de leurs projets numériques.

La TGIR Huma-Num est une infrastructure de recherche française au service de la recherche en sciences humaines et sociales. Elle est bâtie sur une structure originale destinée à proposer des services dédiés à la production et à la réutilisation de données numériques mais aussi à favoriser et accompagner l'émergence d'outils et de bonnes pratiques issus des communautés scientifiques des sciences humaines et sociales. Enfin, Huma-Num est étroitement associée à la construction d'infrastructures européennes permettant tout autant l'échange et la valorisation de services que le renforcement de réseaux d'expertises.

Notre présentation s'articule autour des trois grands axes développés par Huma-Num pour répondre aux besoins de la recherche en sciences humaines et sociales.

- La création et le soutien de consortiums, cercles d'expertise disciplinaires ou non, permettant une concertation collective par les communautés ;
- Le développement de services technologiques destinés à l'outillage des données de la recherche;
- L'ouverture à l'international par la participation à des projets d'infrastructures Européennes mais aussi par des échanges bilatéraux plus ciblés.

Les consortiums réunissent des acteurs issus de structures et de projets de recherche divers, autour de thématiques, d'objets ou de méthodes communs. L'objectif est de favoriser l'appropriation des dispositifs numériques par ces communautés et ainsi de créer des synergies en lien avec les services de Huma-Num. Le spectre des activités de ces consortiums est large, allant, par exemple, de la création d'applications jusqu'à la définition de schéma de métadonnées, en passant par la production de guides de bonnes pratiques associées à des formations spécifiques. Actuellement, Huma-Num soutient les activités de huit consortiums, principalement disciplinaires, qui s'articulent avec le réseau des Maisons des Sciences de l'Homme (réseau géographiquement réparti sur les campus universitaires et du CNRS en France métropolitaine) et dont certains collaborent à des projets européens.

Les services gérés directement par l'équipe de la TGIR Huma-Num sont destinés à fournir des outils tout au long du cycle de vie des données : de la production de données brutes jusqu'à leur préservation après traitement. Pour pouvoir proposer des ressources bien dimensionnées et adaptées, Huma-Num n'a pas créé son propre centre de données, mais s'appuie sur les compétences et les moyens de centres de calcul nationaux français.

L'un des objectifs principaux est de mettre en œuvre un cadre d'outils permettant aux chercheurs d'exploiter au mieux leurs données mais surtout de les amener à les partager et, in fine, à les préserver. Il s'agit de permettre l'appropriation par les chercheurs de méthodes et services numériques au cœur des processus de recherche scientifique. Les technologies d'interopérabilité, en particulier celles proposées par le Web Sémantique, sont au cœur de cette chaine de traitement permettant des échanges fluides entre les différentes briques qui la composent. Le Web Sémantique permet aussi de décloisonner les données de la recherche par l'utilisation de référentiels et normes communs.

Ces outils appuient une démarche générale d'accompagnement des utilisateurs. Ainsi, lors d'une demande d'utilisation, Huma-Num effectue de manière systématique une sensibilisation à la pérennisation, à la curation, au partage des données et aux enjeux de la normalisation.

Ce point est crucial dans le fonctionnement de cette grille de services qui doit aussi permettre la montée en compétence des communautés.

Les activités internationales de Huma-Num sont de différente nature mais elles visent essentiellement à valoriser les dispositifs français d'infrastructure et de la recherche française et à construire un dialogue scientifique et des dispositifs dépassant les frontières nationales. Huma-Num porte ainsi la participation française à des ERICs (European Research Infrastructure Consortium), disciplinaires comme CLARIN depuis 2017, ou à vocation plus large pour les Sciences Humaines en incluant le domaine culturel comme DARIAH depuis sa création en 2014. Ces ERICs, établis sur une longue durée, ne sont pas financés directement par la Commission Européenne mais par les États participants. L'originalité du budget de l'ERIC DARIAH est que 90% de celui-ci est constituée de contributions « en nature » : l'objectif étant de ne pas dupliquer à l'échelle européenne des services qui existeraient déjà au niveau national. Le rôle d'Huma-Num est donc d'identifier les services et expertises nationaux, en particulier ceux en provenance des consortiums et des grands opérateurs français de l'information scientifique et technique et du patrimoine culturel, et d'en faire un ensemble cohérent capable d'intégrer et de compléter l'offre européenne constituée par les partenaires. En parallèle, Huma-Num participe à des projets à plus court terme destinés à soutenir la construction de ces grandes infrastructures et qui sont, eux, financés par la Commission Européenne (dans le cadre des programmes H2020).

Enfin, hors Europe, Huma-Num maintient des liens étroits avec les mondes francophones (e.g. Québec) et hispanophones (e.g. Amérique du Sud). Là aussi, l'objectif est de valoriser les services d'Huma-Num ainsi que ceux issus des communautés nationales et de bénéficier en retour d'échanges d'expertises, notamment dans les domaines de la préservation et de la curation de données issues de la recherche en Sciences Humaines et Sociales.

La TGIR Huma-Num a élaboré sa définition de services technologiques autour du cycle de vie des données. Cette présentation vise à présenter, à partir d'une démarche réflexive, les services d'Huma-Num et la pertinence de leur articulation avec les autres composantes de l'infrastructure que sont les consortiums ainsi que leur projection au niveau international.
En effet, Huma-Num propose des outils adaptés à chaque étape du cycle des données de la recherche :

- Du simple stockage de sauvegarde au début du projet ; Suivant le taux prévisible d'utilisation des données, il est proposé plusieurs solutions technologiques : les données « froides » (i.e. peu utilisées) sont gérées à moindre coûts sur des stockages distribués alors que les données « chaudes » sont mises à disposition via des stockages performants de type NAS ;
- Des outils de traitement des données. Ceux-ci sont mutualisés comme par exemple des logiciels de SIG (Système d'Information Géographique) qui seraient trop couteux à acheter pour une utilisation ponctuelle par un projet. Pour ces opérations de traitements, la TGIR met à disposition une grande puissance de calcul ;
- De l'hébergement Web pour présenter les données et permettre leur partage et leur accès ainsi qu'un travail collaboratif. Pour des besoins plus spécifiques des Machines Virtuelles sont mises à disposition afin d'offrir une grande souplesse d'exploitation ;
- Enfin, et c'est là l'originalité de l'infrastructure, il est proposé un ensemble de services qui permet la diffusion, la citation, la pérennisation et surtout la promotion de la réutilisation de ces données:
    - NAKALA pour stocker des données documentées et les partager, associé à NAKALONA pour les éditorialiser
    - ISIDORE pour diffuser ces métadonnées en les enrichissant, les classifiant et les positionnant dans le LOD (Linked Open Data)

Pour les données qui le nécessitent (e.g. des données de type patrimonial), un service de pérennisation à long terme (plus de 20 ans) en partenariat avec le CINES dont c'est la mission, complète l'offre.

La pertinence des demandes d'ouverture de services est évaluée par un comité interne à Huma-Num qui s'appuie également sur les recommandations de son conseil scientifique.

Cet ensemble de services peut être visualisé de manière synthétique à cette adresse:
http://www.huma-num.fr/services-et-outils

Par ses différentes composantes, la TGIR Huma-Num s'emploie à développer des réponses aux besoins nouveaux des différents acteurs de la recherche provoqués par l'utilisation du numérique. Le fil rouge qui les relie est de pouvoir rendre possibles de nouvelles recherches dans le domaine des sciences humaines et sociales et, au-delà, de constituer de manière dynamique un savoir partagé.

Mining the Cultural Memory of Irish Industrial Schools Using Word Embedding and Text Classification

Susan Leavy

University College Dublin, Ireland

Introduction

The Industrial Memories project aims for new distant (i.e., text analytic) and close readings (i.e., witnessing) of the 2009 Ryan Report, the report of the Irish Government's investigation into abuse at Irish Industrial Schools. The project has digitised the Report and used techniques such as word embedding and automated text classification using machine learning to re-present the Report's key findings in novel ways that better convey its contents. The Ryan Report exposes the horrific details of systematic abuse of children in Irish industrial schools between 1920 and 1990. It contains 2,600 pages with over 500,000 words detailing evidence from the 9-year-long investigation. However, the Report's narrative form and its sheer length effectively make many of it findings quite opaque. The Industrial Memories project uses text analytics to examine the language of the Report, to identify recurring patterns and extract key findings. The project re-presents the Report via an exploratory web-based interface that supports further analysis of the text. The methodology outlined is scalable and suggests new approaches to such voluminous state documents.

Method

A web-based exploratory interface was designed to enable searching and analysis of the contents of the Report represented within a relational database. The relational structure detailed the categories of knowledge contained in the Report along with key information extracted from the text (Figure 1). The Ryan Report is composed of paragraphs containing an average of 87 words. These paragraphs were represented as database instances and annotations detailing semantic content were linked through the relational structure. Named entities were automatically extracted using NLTK (Looper and Bird, 2002).

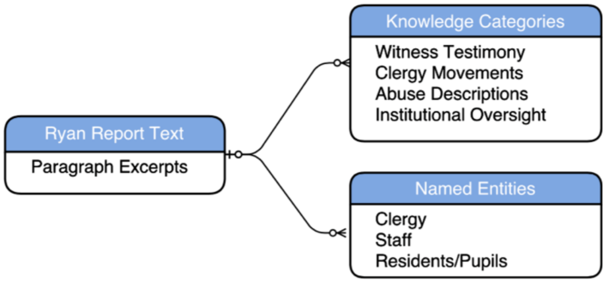

Figure 1: Knowledge Database Relational Structure

Classifying Paragraphs into Different Knowledge Categories

The Ryan Report describes key elements of an enduring system of abuse that operated in Irish industrial schools. Its paragraphs tend to focus on particular topics, allowing them to be classified and annotated. For instance, some cover the extent and nature of abuse, others present witness testimony, report on institutional oversight or on how clergy were moved from one school to another in response to allegations. By classifying paragraphs in terms of these high-level knowledge categories it becomes easier to put a shape on many of the report's findings and to analyse it to provide new readings.

Some of these paragraph-categories were identified using automated text classification. Others were extracted using a rule-based search (e.g., excerpts on institutional oversight). In building classification models, a variety feature sets were examined using a random forest classifier along with manually selected test data. A bag-of-words approach to feature selection yielded results that were over-fitted due to the small samples of training data. However, feature selection based on context-specific semantic lexicons generated from a sample of seed-words using a word embedding algorithm was found to yield accurate results. Lexicons were generated using the word2vec algorithm developed by Mikolov (2013) following an approach identifying synonyms outlined by Chanen (2016).

Movements of Staff and Clergy (Transfer Paragraphs)

An important paragraph-category covers those dealing with the Catholic Church's response to allegations of abuse. The typical response to discovered abuse was to transfer clergy from one institution to another, only for the abuse to re-occur (e.g., *"...Br Adrien was removed from Artane and transferred to another institution..." (CICA Vol. 1, Chapter 7, Paragraph 829))*. Such transfers are described in many different ways in language that often obscures what was happening (e.g., transfers out of the Order, effectively sackings, are described as "dispensations to be released from vows"). We carried out a "by-hand" analysis to find transfer-paragraphs using verb-searches and then expanded this set using machine-learning classifiers.

Initial readings of the Report suggested a set of verbs frequently used to describe the transfer of staff and clergy, including 'transfer', 'dismiss', and 'sack'. The highest-ranking similar words reoccurring over five word2vec models were then identified. Features based on this lexicon, along with names of schools and clergy were extracted from 250 training examples (Table 1). A classification model then classified unseen text from the Report.

Text Category	**Features Extracted**
Direct Speech	Reporting verbs, personal pronouns, punctuation (colons, quotation marks, commas, question marks, contractions), newlines
Movements of Staff and Clergy	Transfer verbs, names of clergy, schools
Descriptions of Abusive Events	Clergy and staff, parts of body, abusive action, emotions and implements associated with abuse

Table 1: Optimal Features Extracted from Report Identifying Witness Testimony

Witness Testimony (Witnessing Paragraphs)

Witness testimonies in the Ryan Report are indicated through reporting verbs and structural speech markers (e.g., punctuation). Using these features, Schlör et. al. (2016) gained accuracy of 84.1 percent in automatically classifying direct speech. Reporting verbs in the Ryan Report are often specific to its context such as apology, allegation or concession. To extract these from the text, highest-ranking similar words across multiple word embedding models were identified based on seed terms generated from WordNet, 'said', 'told' and 'explained'. The resulting context-specific synonyms combined with WordNet synonyms formed a lexicon of reporting verbs tailored to the language of the Report (Table 2). A classification model was developed using these features along with punctuation information using 500 training examples.

Seed Words	Context Specific Lexicon for Reported Speech				
said	answered	alleged	warned	enounced	explained
told	learned	recounted	claimed	verbalise	believed
explained	confirmed	surmised	denied	verbalised	added
	described	relieved	asserted	assure	replied
	say	protested	witnessed	articulate	thought
	tell	stating	called	apologise	knew
	told	describes	informed	pardon	felt
	state	agreed	said	pardoned	recalled
	posit	admitted	explained	remember	saying
	posited	convinced	advised	articulated	told
	submit	presumed	assured	enounce	thinks
	submitted	screams	tells	condoned	remembered
	express	reported	requested	condone	conceded
	expressed	complained	heard	saw	realised
	narrate	asking	says	explicate	stated
	narrated	commented	confessed	explicated	insisted
	recount	questioned	remarked	apology	guarantee
	recite	accepted	alleged	concluded	asked
	recited	recollection	suggested	mentioned	

Table 2: Context Specific Synonyms Using Word Embedding

Descriptions of Abusive Events (Abuse Paragraphs)

To evaluate the scale of abuse throughout the industrial school system, excerpts from the Report detailing abusive events were extracted. The language describing abuse incorporates a broad range of linguistic features. A set of seed-words from which to base a semantic lexicon for feature extraction, was not immediately apparent on reading the Report. A support vector machine algorithm was therefore used to extract the most discriminative features based on a sample set of 200 paragraphs.

Analysis of the support vectors showed that terms distinguishing excerpts describing abuse formed five categories: abusive actions, body parts, emotions engendered in the victims, implements and names of staff and clergy. Sample words associated with each category were then used as seed-words to generate word embedding models to extract similar terms from the Report. Features based on these five lexicons, combined with names of clergy and staff were then used to generate a predictive model of abusive events.

Findings and Conclusions

This research demonstrates how word embedding can be used to compile context-specific semantic lexicons to extract features for text classification. These features allowed paragraphs for each knowledge category to be automatically classified based on manually selected training data.

Classification	No. Classified Excerpts
Clergy Movements	1,340
Direct Speech	1,920
Abusive Events	1,365

Table 3: Total Number of Classified Paragraphs

The performance of classifiers was evaluated using 10-fold cross-validation on the training data and showed high levels of accuracy in categorisations (Table 4).

Classification	Precision	Recall	F-Score	Accuracy
Clergy Movements	.91	.91	.91	91.2%
Direct Speech	.94	.93	.93	93.6%
Abusive Events	.93	.93	.93	93.3%

Table 4: Performance on Training Data: Random Forest Classifier. Weighted Average Results Using 10-fold Cross-Validation

The classification models were applied to unseen data and performance evaluated by manually inspecting classifications of 600 randomly selected excerpts from the Report as shown in Table 5. Though overall accuracy levels remained high, precision of the classifications did fall somewhat, especially in relation to identifying speech and transfers.

Classification	Precision	Recall	F-Score	Accuracy
Clergy Movements	.58	1.0	.73	92%
Direct Speech	.84	.92	.88	94%
Abusive Events	.86	.88	.87	95%

Table 5: Performance on Unseen Text: Classification of Report Evaluated on Random Samples

Error analysis showed that incorrectly classified excerpts (false positives and negatives) were commonly those where the meaning of the language was subtle or vague. Paragraphs incorrectly classified as quoted speech for instance, were in fact quotations from letters and diary entries. Unidentified speech excerpts all consisted of short quoted phrases.

Transfers of clergy were reliably detected. However, there was a high rate of false positives due to the fact that the transfer of children throughout the school system is described using similar language (e.g. "*The witness remembered … when he was leaving Artane at nine years of age…" (CICA Vol. 1, Ch. 7, Paragraph 466)*). Classifying excerpts describing abuse yielded few false positives but it also returned the highest levels of false negatives. In these instances, references to abuse was subtle or addressed emotional abuse. As such, it was necessary to manually filter results.

This paper has demonstrated that machine learning can be used to classify text based on a limited number of examples, when used in conjunction with word embedding to generate context-specific semantic lexicons. Re-presenting the Ryan Report in the form of a relational database with a web-based exploratory interface has facilitated comprehensive analysis of the Report, and has exposed new insights about the dynamics of the system of child abuse in Irish industrial schools. In reformulating how the Ryan Report can be presented, this research presents a scalable approach to digital analysis of state reports.

Real and Imagined Geography at City-Scale: Sentiment Analysis of Chicago's "One Book" Program

Ana Lucic
alucic@depaul.edu
DePaul University, United States of America

John Shanahan
jshanah1@depaul.edu
DePaul University, United States of America

Since fall 2001, the Chicago Public Library (CPL) has chosen fiction and nonfiction around which to organize city-wide public events, book discussions, and other creative programming. This "One Book One Chicago" (OBOC) program has been a successful ongoing civic initiative with great public visibility, with participants ranging from the Mayor of Chicago to countless book group volunteers across the city. Our "Reading Chicago Reading" project—supported by the National Endowment for the Humanities Office of Digital Humanities and Microsoft—works to discover how text characteristics, library branch demographics, and promotional activities are linked variables that can be used to predict patron response to future OBOC titles. The OBOC program acts as a recurring experiment in data capture, for each chosen work represents a probe into library usage and, by extension, a window onto the elective reading behavior of the diverse patrons of a major American city.

This paper will report comparative circulation data for three recent OBOC choices that are Chicago-centered and three that are not Chicago-centered. The three Chicago-centered books are:

1) *The Adventures of Augie March* (1953) by Saul Bellow
2) *The Warmth of the Other Suns* (2011) by Isabel Wilkerson
3) *The Third Coast* (2014), by Thomas Dyja

The three recent non-Chicago OBOC choices are:

1) *The Book Thief* (2007) by Markus Zusak
2) *The Amazing Adventures of Kavalier and Clay* (2000) by Michael Chabon
3) *Gold Boy, Emerald Girl* (2010) by Yiyun Li

We are keen to answer whether a Chicago setting and, more particularly, particular measures of linguistic sentiment about Chicago people and places, have measurable influence on the popularity of books across Chicago. Specifically, we are interested in examining the question of whether "Chicago" books, fictional and nonfictional, checked out in greater numbers when they feature characters, events, and places situated close to the readers' own neighborhood library branch? (We use CPL library branch as a proxy for patron home address, which we cannot know from the library system's anonymized checkout data.)

The results of this analysis have the potential to provide empirical answers to long-standing questions in digital humanities research: in his Atlas of the European Novel 1800-1900, for example, Franco Moretti speculated that perhaps "fictional spaces are particularly suited to happy endings," but did not have hard numbers to judge one way or the other at the time (18 n.6). More recently, in The Bestseller Code, Jodie Archer and Matthew Jockers argue that "while it does matter whether an author chooses a city or the wilderness, the specific city does not matter all that much when it comes to bestselling" (227). Our sentiment analysis findings will contribute to open research questions: maybe in fact the city matters when readers are in that city, and when the places and people in that same city are written about in particular linguistic registers. If literary form and real geography do have detectable ties to one another, our project ought to be able to capture the effect.

To compare the circulation pattern of non-Chicago and Chicago-related OBOC books, we used one year of city-wide circulation data for each book, starting with the date of the title's public announcement as the OBOC choice. This data was normalized by dividing the circulation raw numbers with the total number of visitors for that year and multiplying the result by 1000. Normalizing by the number of circulated copies was sometimes difficult because some branches did not have any copies (but could borrow them from other branches). Given that libraries oftentimes allocate books based on the size of the library and based on the number of visitors, we decided to normalize by the overall number of visitors. Distribution patterns for Chicago and non-Chicago related sets of books are represented through the histograms and QQ plots in Figure 1. As this analysis indicates, the circulation distribution across 79 Chicago library branches does not follow bell-shape distribution and is positively skewed. The Wilcoxon signed rank test was used to test to what degree the difference in the distribution for these two sets can be attributed to chance.

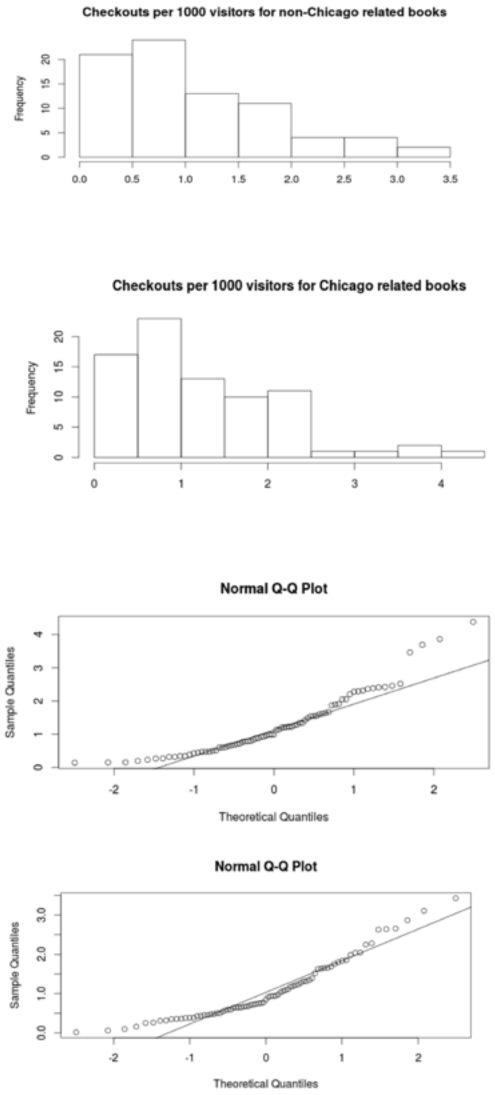

Figure 1. On top, histograms representing checkouts per 1000 visitors for non-Chicago related and Chicago related books. Below, the QQ plots for non-Chicago and Chicago related books checkouts.

Results indicate that the probability that the difference in the circulation distribution across 79 Chicago library branches for the two (paired) sets of books can be attributed to chance is very low (p < .01).

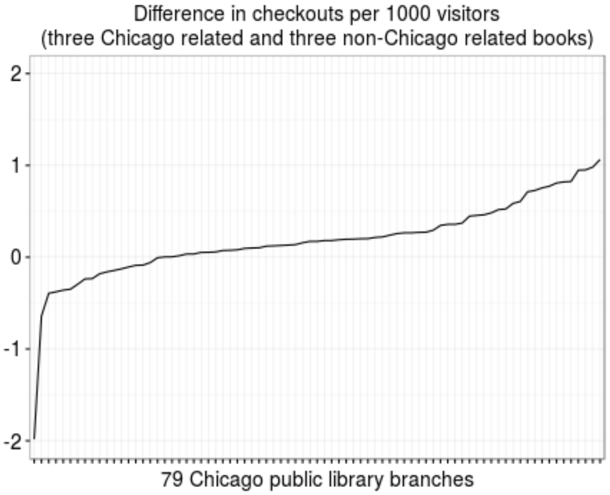

Figure 2. The y-axis indicates the difference in the checkouts (1-year of circulation data) for three Chicago related and three non-Chicago related books.

The y-axis in Figure 2 represents the difference between the checkouts per 1000 visitors for Chicago related and non-Chicago related books. Figure 2 indicates that the three non-Chicago related books circulated more than the set of Chicago related books in some library branches in the Chicago area (where the line drops into negative difference). In some branches, however, the difference is almost minimal. The plot also indicates that, in some branches, the OBOC Chicago-related choices had, in fact, more checkouts than the non-Chicago OBOC choices (where the difference is positive). Although it is difficult to establish which factors contribute to this difference in circulation and although we cannot attribute this difference between the two distributions to the mere fact that one set contains references to Chicago whereas the other does not, we plan to represent the library branches that are associated with a larger number of checkouts for Chicago non-related books and those that are associated with a larger number of related books on the Chicago map and analyze them against the sociodemographic and socioeconomic characteristics of different branches (obtained from the American Community Survey data). In the future, we plan to add more Chicago related books to the analysis and observe how this may affect this observed pattern.

A further question of interest to us is, do the sentiment measures for these texts map in consistent ways for different neighborhoods? To examine these questions, we rely on Stanford CoreNLP natural language processing capabilities (Manning et al., 2014). Given that the identification of places and locations is important for our analysis, we use a tool that has consistently achieved good rankings and, in general, boasts superior accuracy rates when compared to other named entity recognizers (Rodriquez et al., 2012; Atdağ & Labatut, 2013): the Stanford Named Entity Recognizer, a part of the CoreNLP suite of tools. Before running the named entity recognizer, the text is first tokenized into sentences using the NLTK sentence tokenizer. The CoreNLP program then tokenizes sentences into words, identifies lemma for each individual word, uses the Penn Treebank part of speech information (Toutanova & Manning, 2000), and also notes Persons, Locations, Time Reference, and Numbers in the sentences (Finkel et al., 2005). We are specifically interested in locations as this category would not only identify Chicago as a location but also its streets and landmark buildings. For sentiment analysis, we are using the Stanford sentiment analysis tool (Socher et al., 2013)—also part of the Stanford CoreNLP—to annotate each sentence with the sentiment score on the following scale: Very Positive, Positive Neutral, Negative, Very Negative.

Preliminary analysis on the sentiment associated with sentences that contain the word Chicago in the three Chicago-related books is indicated in Figure 3:

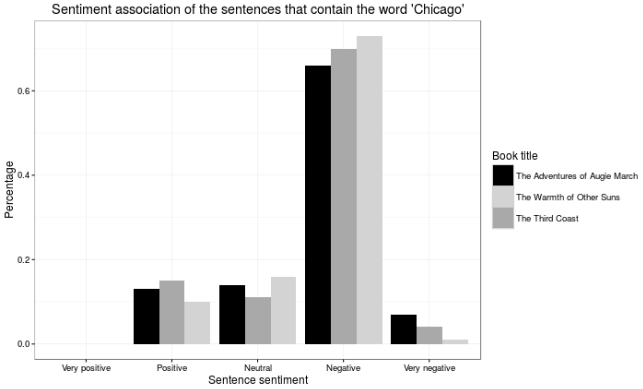

Figure 3 Sentiment distribution of sentences that contain the word Chicago in Augie March, The Warmth of Other Suns, and The Third Coast

The raw count of sentences with their sentiment ratings was normalized by the total number of sentences that contain the word Chicago. Noticeable in Figure 3 is that although these three books differ according to genre, and although they differ in terms of topical coverage and date of publication, we see a rather similar sentiment score pattern with respect to sentences that contain the word Chicago. We suspect that this overall similarity pattern will start to change as we dig deeper into the location data: we must note here that this initial analysis above does not yet take into account local references such as Pizzeria Uno, Pullman, the South Side, Monroe Street, and the like, but do not also use the word Chicago in the sentence. We plan to obtain a set of place names associated with Chicago through resources such as Open Street Maps and GeoNames and search for all the occurrences of Chicago place names. Additionally, we plan to use the indexes in the back of some of the books as trusted sources of local place names.

Introduction

Visualization techniques developed in the sciences normally focus on the (re)presentation of empirical data. But how can we graphically express *interpretations*? This paper presents the intellectual framework underpinning the 3DH project (Three-dimensional Visualizations for the Digital Humanities), a collaborative project conducted at the University of Hamburg from 2016 to 2019. The project foregrounds data interpretation and develops a visualization paradigm from the epistemological perspective of the humanities. The "third dimension" required in DH visualization techniques is therefore not merely that of an additional quantitative z-axis. Rather, it is an axis that can 'unflatten' (Sousanis 2015) the objectivist notion of visualized data. In our presentation, we will do three things:

- **Digital and visual turn:** Review existing visualization paradigms that emphasize the representational approach. We start with the epistemological issues raised by the digital and visual turn.
- **Visual modelling:** Outline and discuss an interpretative modelling alternative through two case studies of existing tools, CATMA and Voyant, and Temporal Modelling, a platform for creating data through graphical means.
- **"Hermeneuticizing" visualization:** Discuss the design of a full visual framework. We will present possible conventions and prototypes that use them. These inform our case studies and the envisaged infrastructure.

Case studies in our presentation will be drawn from CATMA (a collaborative mark-up & text analysis environment), Voyant (a text analysis platform), and humanities research projects using base images (historical maps) and original models (for non-standard chronologies).

The digital and the visual turn: a hermeneutic ceterum censeo

For centuries, academic discourse in humanities disciplines has relied predominantly on text. In DH, however, visualizations increasingly claim the status of arguments and proofs that play a decisive role in the development and presentation of ideas, findings, and conclusions.

The visual and the digital turn have thus gone hand in hand – but the way in which this synergy manifests itself remains constrained in a symptomatic way. We can print a chart or render it on screen just as we can print or display a text in various media, but we normally cannot subject the chart to in-depth critique in the way we can question and respond to the text. Inadvertently, once generated and communicated as 'output', visualizations seem to take on a quasi-dogmatic quality – they are hard to deconstruct, let alone reconfigure; they state their case but seem removed from critical reflection.

Most current DH visualizations are thus epistemological one-way avenues toward knowledge, from data via rendering algorithm to visual display. Charts, graphs, interactive maps, timelines, and similar representations are by and large imports from the natural and social sciences (Friendly 2008). Many of them emanate from domains of empirical research that conceptualize knowledge production as a function of empirical observation and objective measurement followed by analysis, inference, and conclusion. These approaches to visualization, however, hide two critical aspects, namely

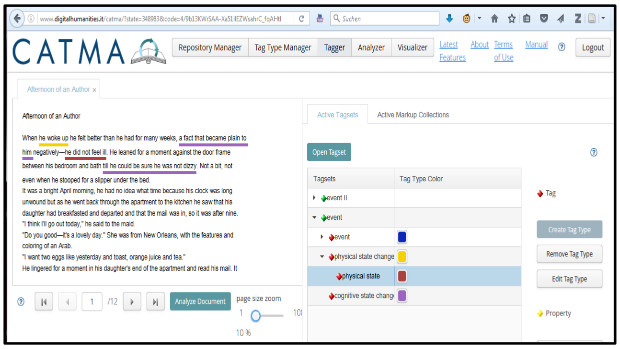
(a) the underlying human modeling of the represented phenomena *as* data, which is already an interpretive and meaning-*creating* act that often oscillates repeatedly between observation and interpretation (Kitchin 2014), and
(b) the meaning-*lessness* of certain visual effects that are owed to contingent technological constraints (screen size, rendering, scaling, choice of color, etc.).

DH is in a unique position to investigate the domains of human experience and of its expression in symbolic practices and artefacts from two complementary methodological vantage points: the numeric, which models them as statistical phenomena, and the hermeneutic, which explores them as phenomena of *meaning* and thus by definition as a function of interpretation (Rockwell & Sinclair 2016). Where *meaning* comes into focus, our theories, object models, and practices must therefore be conceptually aligned and 'hermeneuticized' – just as numeric approaches come with the pre-requisite of quantification. Against this backdrop, we propose to reintroduce the dimension of interpretation into visualization: Methodological principles of hermeneutic approaches, such as multi-perspectivity, subjectivity, and context-boundedness present a challenge which representational visualization cannot and which interpretational visualization must meet.

Two questions arise: What are the defining principles of a genuinely humanistic and hermeneutically oriented approach to visualization? And how can we graphically express and support interpretation in DH visualizations – both as an *activity* and as a *product* of humanistic enquiry?

Visual modeling of interpretation vs. visualization of data

In the 3DH project, we address the former question by conceptual analysis and critique of existing approaches to visualization in DH, and then by systematically specifying and developing a visualization environment that can support higher level data interpretation rather than base-level data representation. In the presentation, we will share our survey of existing tools and their affordances but focus on two tools that we have developed, CATMA and Voyant.



Afternoon of an Author

When he woke up he felt better than he had for many weeks, a fact that became plain to him negatively—he did not feel ill. He leaned for a moment against the door frame between his bedroom and bath till he could be sure he was not dizzy. Not a bit, not even when he stooped for a slipper under the bed.
It was a bright April morning, he had no idea what time because his clock was long unwound but as he went back through the apartment to the kitchen he saw that his daughter had breakfasted and departed and that the mail was in, so it was after nine.
"I think I'll go out today," he said to the maid.
"Do you good—it's a lovely day." She was from New Orleans, with the features and coloring of an Arab.
"I want two eggs like yesterday and toast, orange juice and tea."
He lingered for a moment in his daughter's end of the apartment and read his mail. It

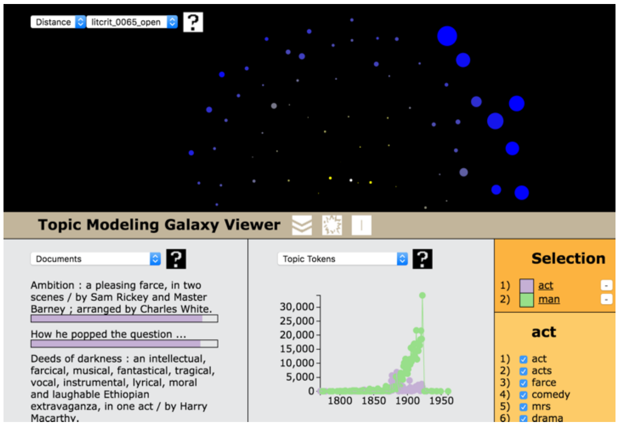
Figure 1: Visualization of interpretive text annotation in CATMA

Our premise is that interpretation happens through the deliberate activity of an individual engaging with an image, text, display, or other artifact *to create an argument about its meaning and a way it should be read*. For example, in CATMA (Figure 1) such an activity – in this instance the interpretive act of text annotation – is executed and represented by (a) highlighting a string on screen, (b) assigning it a tag, and (c) storing the annotation in a stand-off markup file. However, the annotation is at the same time (d) visually expressed as colored underlining. Moreover, via its visual representation on screen – the colored underlining – the markup data can also be (e) inspected, analyzed, manipulated directly, and even (f) enriched with meta-annotation. This is but one example of interpretative modeling.



Ambition : a pleasing farce, in two scenes / by Sam Rickey and Master Barney ; arranged by Charles White.

How he popped the question ...

Deeds of darkness : an intellectual, farcical, musical, fantastical, tragical, vocal, instrumental, lyrical, moral and laughable Ethiopian extravaganza, in one act / by Harry Macarthy.

Figure 2: Galaxy Viewer

Current representational 'one-way' techniques like topic modeling (see Figure 2) are seen as a way to deal with scale, they process large amounts of data into summary abstractions called topics that can be displayed as lists or in other ways (Montague et. al 2015). In our second case study, we will therefore show how we are adapting scale tools to create a prototypical bi-directional 3DH visual modeling environment for big data. We believe visual modeling can support not only interpretative close reading of primary data but also the reading of large collections like the collections of the Hathi Trust.

'Hermeneuticizing' base-level visualization through activators: the 3DH framework of interpretive parameters and dimensions

A key goal of the 3DH project is to develop a set of generic graphic features that can be used to create interpretative attributes and/or inflections of visual representations of data, alter underlying data structures, and activate three-dimensional space in the service of interpretative activity. These features which aim to 'hermeneuticize' visualizations are termed *activators*. In the presentation we will show the framework of the activator set that was developed during a series of *charettes* (design workshops) in 2016.

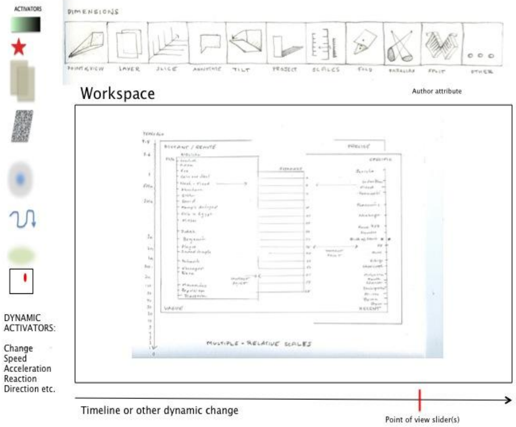


Figure 3: Framework of Concept Modeling workspace: Shows features, activators, and dimensions from various pictorial conventions.

The visual activators in our feature set are not simply graphical marks or animations on a screen display: They perform data structuring functions and as such provide a conceptual framework for 'hermeneuticizing' existing base-level data visualization techniques (see Fig.3). The individual features of this framework indicate and facilitate interpretative moves made by the user, such as a qualification of visualized data structures in terms of salience, irrelevance, uncertainty, degree of completeness, and other attributes or inflections. For example, uncertainty can be expressed by overlaying a standard graph with visual effects such as blur or shading, whereas the introduction of additional interpretative dimensions, such as point of view systems, parallax, relative scales, and other conventions from the visual arts, will support higher levels of interpretative critique and reflection, such as explicitly marking the historicity and context-dependency of underlying data.

Conclusion

As Pinker (1990) argues, the ease with which a particular graph can be understood is a function of the processing effort that goes into the exercise: The more we can rely on 'hard-wired' encoding connections between the visual and the conceptual and the more we are guided by established graph and comprehension schemata (such as Gestalt phenomena), the less 'intelligent' effort we have to put into reading a graph. Yet in a humanities perspective such conventionalized 'ease of comprehension' is a double-edged sword: It may optimize the process of (re)cognition – but it also progressively obscures the constructedness of a visualization, turning it into an apparently self-evident object of perception. The 3DH project counters this anti-hermeneutic tendency toward reification by moving from a conceptualization of the principles of visualization as *interpretative* modeling to the development of a visual language framework, and finally the instantiation of the principles and language in two case studies. In terms of implementation, this approach is supported by drawing on Bertin's *Semiology of Graphics* and the high-level object-oriented *Grammar of Graphics* approach outlined by Wilkinson (2005), and features from game engines, three-dimensional modelling, and other pictorial conventions (Panofsky (1991) and Burgin (1991)).

To conclude, we will discuss next steps toward developing a 3DH environment that can act as a generic, project independent infrastructure for introducing user parameterized enunciative functionality into graphical displays. This infrastructure will make it possible to inscribe into visualizations the critical features of authorship, speaking/spoken subject, and an epistemological perspective grounded in situated and constructed approaches to knowledge. These interpretative principles are well mapped in, e.g., critical theory, narratology, visual studies, and cultural studies, but they have not been integrated into a graphical environment for hermeneutic practice yet: the methodological lacuna which the 3DH project tries to address.

Regrowing Egyptian cults: The potential of using modern computational methods in the study of ancient religions

Introduction

Historical sources provide us only a fragmentary testimony of historical processes. The survival of specific sources and the information they contain is very often determined by chance. Because of these circumstances, the reconstruction of many historical processes remains problematic or, in some cases, almost impossible. In addition to these problems, some long-term historical processes are very difficult to recognize from the perspective of "event history" due to their gradual nature. The interdisciplinary project GEHIR (Generative Historiography of Religion) at Masaryk University strives to, within the framework of the historically oriented study of religions, adopt innovative methods used in the study of the dynamics of complex systems, i.e. methods including mathematical and geographical modelling, agent-based simulations or network analysis. Within the study of historical processes these formalized methods are conceptualized as an innovative third way through which the limitations of the traditional inductive analysis of historical sources and deductive application of social-scientific and cognitive theories to social and historical phenomena can be overcome. In this paper we would like to introduce the results from a case study within the GEHIR which focused on uncovering the possible factors influencing the early spread of the cults of Isis and Sarapis in the ancient Mediterranean.

Methods

In this project, traditional methods of historical research such as critical analysis of the archeological and literary sources or categorization of the historical evidence in the form of relational database were supplemented by the following computational methods:

- **Network analysis** is currently used in various areas of historical research, mainly to understand and analyse complex structures, e. g. trading cities in state, social groups. There are a number of historical research papers that have used network analysis; the work of Rivers et al (2012) should be mentioned.
- **Environmental/geographical modelling** is used to reconstruct the potential of locality within an examined phenomenon that is even partially spatially-dependent. It offers a unique opportunity for researchers to understand how spatial conditions are related to other events. The work of Turchin et al (2013) and others could be used as an illustration of such methods.
- **Mathematical statistical analysis** aims to find hidden logical patterns and existing correlations within multiple phenomena that may subsequently be interpreted in the context of the research questions. Various methods and approaches can be used, including clustering, multidimensional analyses, and exploratory data analysis.

Case study: Egyptian cults in the Aegean Sea region

Early in the Ptolemaic era, in the period between ca. 305 - 167 BCE, the Egyptian cults, particularly those of Isis and Sarapis, spread successfully to ports in the ancient Mediterranean. The reasons behind this process are, however, only partially understood. The original and still respected hypotheses in the academic discussion emphasize either the maritime trade (Fraser, 1960) or Ptolemaic political propaganda (Cumont, 1911:78-80) as key factors in the spread of these cults. Both of these claims are supported by historical evidence. Ptolemaic Egypt was one of the main exporters of grain, Isis was a patron goddess of sailors and many cities in the ancient Mediterranean had close diplomatic relations with the Ptolemies.

To specify our area of interest, this research is mainly focused on the early spread of the Egyptian cults in the area of the Aegean Sea, particularly the Aegean islands. There are several reasons for this selection:

- the main trading routes between Alexandria and continental Greece passed through that particular area with the Aegean islands as potential places of Egyptian interest.
- the first Ptolemies were politically invested in the Aegean using the islands as strategic locations for military bases and administered the Island league.
- islands are more isolated worlds and thus more suitable for modelling.

In order to clarify these hypotheses, we sequentially applied the described computational methods to the issues of maritime transport network reconstruction, approximation of the urgency of importing goods, evaluation of positional advantages of particular islands, and statistical correlation of different modelled factors.

The first task was to reconstruct the maritime transport network, as this was the backbone of ancient Mediterranean trade. For this purpose, Pascal Arnaud's collection of ancient maritime routes were scanned and geo-referenced in GIS software and all the routes within the area of interest were redrawn. This network was then validated and modified by the location of ancient ports, the AWMC map and geometries of islands. Afterwards, we were able to use network analysis to calculate centrality values in order to approximate attractiveness of harbours.

As strategic positioning is not the only determinant of trade intensity, we also decided to estimate the ratio of agricultural potential and the number of inhabitants on each island. This can then be used as an approximation of the urgency of goods import. Food production was measured based on the geographical environmental model we created. Various approaches to population estimates were put forward and discussed. We decided to use historical censuses from the 19th century, as they were taken before the demographic transition in the area and the population values should more or less correlate.

In order to validate the hypothesis emphasizing the Ptolemaic political actions as a key factor of the spread of the cults, we also needed to define the political factors. The Ptolemaic garrisons dispersed in the Aegean Sea are of great importance in our research because many of them were maintained for a long period of time and could thus increase the chance of spreading the cults via Ptolemaic soldiers. The second potential factor influencing the spread of the Egyptian cults is the existence of political leagues. In the context of the Aegean Sea, Ptolemies led the Island league from ca. 287 to 250s BCE. Again, this political factor is relevant because it is geographically delimited and lasted for a longer period of time.

The final and perhaps the most important dataset includes the locations of the Egyptian temples and artefacts from the above specified spatio-temporal frame (see Figure 1), collected from the RICIS catalogue (Bricault, 2005).

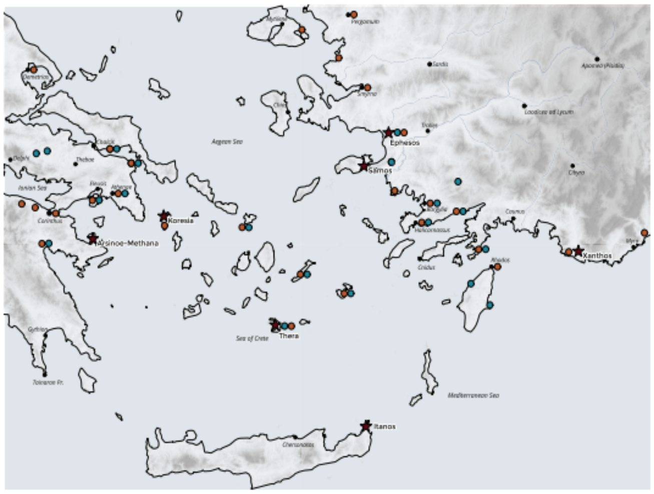

Figure 1: Map of the Aegean Sea region and locations of relevant temples (blue dots) and artefacts (red dots) of Egyptian cults, as well as Ptolemaic military garrison placements (stars).

Geographical analysis was used to calculate distances from each island to the closest army base and temple in order to evaluate spatial dispositions.

The final part of the research is the statistical analysis of data obtained in previous steps. At that point we had a table containing the list of islands with their attributes based on the data (e.g. if an island occupied a strategic position on the network, or if it had a Ptolemaic garrison) and the goal was to find a solid and interpretable mathematical model that would be able to find and explain relations between these values, mainly their dependency on the distance to the closest temple on the network.

Results and Conclusions

The mathematical model we selected using the statistical analysis of covariance uncovered a few patterns within our datasets. The results suggest that there is a strong correlation between the placement of the Ptolemaic garrisons and the dissemination of Egyptian temples and artefacts in the Aegean sea. The interpretation would, in this case, be that the Egyptian military forces potentially played a significant role in the spread of the cults. However, the analysis also showed that in areas far from these military bases the islands with higher trade attractiveness intensified the presence of the Egyptian cults.

The main task of this paper is to show how we can "regrow" the Egyptian cults in space and time using innovative computational methods from multiple disciplines. This allows us to validate the selected hypotheses from the academic discussion constructed by using traditional historiographical methods. We see great potential for using these approaches in the other case studies of GEHIR, as well as in historiography in general.

Variation in academics' conceptions of e-assessment

Mike Mimirinis
mike.mimirinis@anglia.ac.uk
Anglia Ruskin University (Cambridge), United Kingdom

Earlier research in academic development proposed that enhancing teaching often derives from changes in how teachers think about their own teaching (Dall'Alba, 1991). Accordingly, the current study postulates that academic teachers conceptualise e-assessment in a number of qualitatively different ways; some of them may replicate traditional pedagogical approaches and merely transfer them to blended or online assessment settings while others may endorse transformational notions of assessment, underpinning knowledge construction and student agency. The study aims to synthesize and extend the findings from two existing clusters of studies. The first cluster derives from qualitative, non-phenomenographic research exploring conceptions held by academics about assessment without taking into account the layer of complexity brought about by technological tools. Influential studies in teachers' conceptions of teaching and learning identified a continuum of conceptions ranging from teacher-focused and content-oriented conceptions on the one end to student-focused and learning-oriented on the other end (for a review see Kember, 1997). Entwistle (2000) noted that *limited* evidence suggested that contrasting conceptions of teaching tend to hold corresponding views on assessment. Several studies also contended that teachers' conceptions of learning and teaching affect their approaches to teaching (e.g. Kember & Kwan, 2000). However, there have been no extensive, follow-up studies aimed at ascertaining whether contrasting conceptions of teaching are aligned to corresponding views on assessment or what the exact nature of such an alignment may be. Samuelowicz and Bain (2002) identified a continuum ranging from an emphasis on knowledge reproduction to an emphasis on knowledge construction and transformation and Postareff et al. (2012) described categories of conceptions, from reproductive conceptions to more transformational conceptions of assessment. The second cluster consists of phenomenographic studies in the area of conceptions of teaching and learning through technologies. These studies investigated university teachers' conceptions of, and approaches to e-learning (e.g. Ellis et al., 2009; González, 2010) and blended learning (Ellis et al., 2006). They did not, however, take into account assessment as a distinct element of the process of university teaching.

The adopted phenomenographic approach aimed to describe the phenomenon from the perspective of people involved with the phenomenon (Marton & Booth, 1997) i.e. teachers e-assessing within blended and online environments. Twenty participants have been invited to attend semi-structured interviews - preceded by two pilot interviews. The sample was drawn from teachers of a modern British university; a wide number of disciplinary backgrounds and academics with differing levels of experience was sought. The interviewers prompted academics to describe *possible* ways of utilizing e-assessment tools, their experiences of practicing e-assessment in general and details about a particular e-assessment practice they are engaged in. Participants were invited to explain what the purpose of the e-assessment was, how they understood their role in e-assessment and what they believed the role of the student was. Rounds of iterative analysis produced four qualitatively different, hierarchically-inclusive and logically-related categories of how academics conceive of e-assessment. E-assessment has been seen as a means: (i) managing and streamlining the assessment process (ii) communicating and engaging with students (iii) enhancing student learning and the quality of teaching (iv) community and (digital) identity building. The paper also reports on dimensions of variation, most importantly the role of the teacher/assessor, the role of the student, the level and quality of collaboration, the role of the technological medium and, finally, who benefits from the e-assessment processes. Conclusively, variation in the way academics conceive of e-assessment is discussed in light of previous studies in this area; implications for faculty development are approached under the lens of expanding awareness i.e. how can faculty development promote qualitatively more advanced conceptions of e-assessment and how can such interventions can improve student learning.

eLexicon. Dictionary of Polish Medieval Latin: from TEI encoding to an eXist-db application

Krzysztof Nowak
krzysztof.nowak@ijp-pan.krakow.pl
Polish Academy of Sciences Krakow, Poland

Introduction

From the *Lexicon* to the *eLexicon*

The first fascicle of the *Lexicon mediae et infimae Latinitatis Polonorum* (Dictionary of Polish Medieval Latin, henceforth LMILP) was published in 1953. The project aims at providing an exhaustive account of the Latin vocabulary used on Polish territory during the Middle Ages. Addressed to a scholarly public, the dictionary does not make many concessions to a less advanced user. Information is often conveyed only indirectly, by means of typographic devices or is left to be inferred by the reader. The project of retro-digitization of the LMILP started in the mid-2011 and was completed by the mid-2014. The web application, although completed, is still subject to modifications and refinements.

Dictionary Annotation

The XML encoding of the dictionary was by no means an ultimate goal of the project. Instead, the idea was to make the rich content of the LMILP fully searchable through a user-friendly interface. This objective, however, has deeply influenced the XML schema design. The TEI (TEI Consortium 2016) was chosen as an annotation standard because at the time the work started it had been already employed in major electronic lexicography projects (Lewis-Short by the Perseus Project; DuCange by the ENC). The popularity that the standard had gained among scholars contributed to emergence of lively community which produced documentation and use cases which supplemented the "Dictionaries" chapter of the TEI Guidelines. Also, the very fact that the TEI Guidelines offered a set of ready-to-use tags for the description of lexicographic content was not without significance. Finally, the TEI XML was supported by major software providers, an important factor for the project in which adaptation of existing rather than writing new software was planned.

Workflow

The paper dictionary was scanned and the output of the OCR program (Abbyy FineReader 11) was exported to ODT files; from each a *content.xml* file was extracted and then applied a series of XSL transformations. The main goal was to simplify styles that were automatically generated by the OCR software. Resulting XML files underwent second phase of XSL processing in which constitutive parts of the dictionary, such as entry, headword, sense definition *etc.*, were encoded. The output XML files were again re-translated into ODT format: entries were encoded as paragraph styles, other tags were represented as character styles. In the next phase of the project the lexicographers started to proofread OCR text and correct errors of automatic annotation. This task was performed with the help of LibreOffice Writer exclusively without annotators being actually conscious of the underlying XML structure. From the practical point of view, annotation consisted in verifying whether automatic XSL processing produced correct styles; if this was not the case correct style had to be applied, as in standard text processing task.

Fig. 1: "XML-unaware" annotation in the LibreOffice window

This approach allowed for reducing the learning curve to a minimum so that the team members could focus on the lexicographic content. However, it also has a serious drawback: annotation in the text editor cannot produce more complex hierarchies, since paragraph and character styles allow for representing at best two levels deep nesting.

TEI for the *eLexicon*

A guiding principle of the subsequent TEI annotation was to combine *editorial* and *lexical view* of the dictionary content by (1) preserving its original text and (2) storing normalized data in attributes and empty XML elements. Typographic properties of the text, on the other hand, were not generally encoded, they are easily reconstructible though.

Automatic and manual annotation consisted in three major procedures:

a. translation: custom ODT styles (corresponding to elements of dictionary structure) were "translated" into respective TEI elements or attributes;
b. grouping: deeply nested XML structure was produced from flat annotation;
c. enrichment: implicit information was made explicit.

Translation

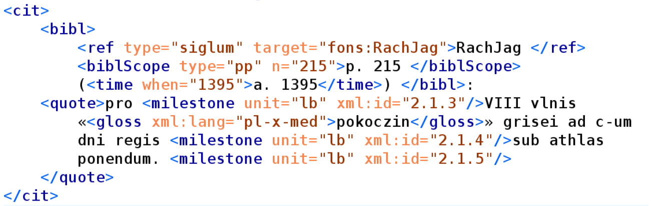
The paper justifies some of the annotation choices. Special attention is given to the peculiarities of encoding a scholarly lexicographic work.

1. **<entryFree>** element was chosen as a container for dictionary entries.
2. Essential features of the dictionary macro- and microstructure are encoded as: **<form>, <orth>; <gramGrp>, <gen>, <iType>, <pos>; <etym>, <lang>, <mentioned>; <cit>, <bibl>, <biblScope>, <date>, <quote>; <sense>, <usg>, <def>, <gloss>; <xr>, <ref>; <lbl>; <re>, <certainty>, <oVar>, <note>.**
3. Content and form peculiarities of the LMILP are reflected in respective attributes. So, for example, functional variation of the entries is represented in the **@type** attribute of the **<entryFree>** and can take one of the following values: **main, xref, hom.**
4. The TEI schema was only lightly customized: unused elements were deleted; a few content restrictions were overcome.

Grouping: adding depth

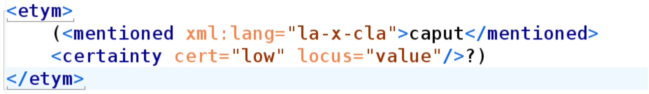
The flat entry structure had to undergo heavy XSL processing, so deep nesting typical of scholarly dictionaries could eventually emerge. Relative ease of the XML-unaware manual annotation resulted in time-consuming post-processing. The **xsl:for-each-group** XSL function was employed in order to structure:

1. citation groups:



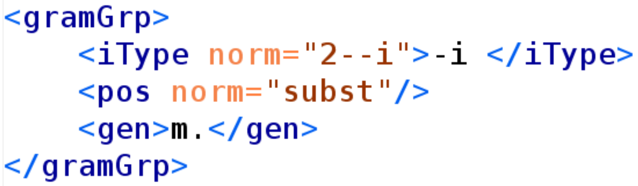
```
<cit>
    <bibl>
        <ref type="siglum" target="fons:RachJag">RachJag </ref>
        <biblScope type="pp" n="215">p. 215 </biblScope>
        (<time when="1395">a. 1395</time>) </bibl>:
    <quote>pro <milestone unit="lb" xml:id="2.1.3"/>VIII vlnis
        «<gloss xml:lang="pl-x-med">pokoczin</gloss>» grisei ad c-um
        dni regis <milestone unit="lb" xml:id="2.1.4"/>sub athlas
        ponendum. <milestone unit="lb" xml:id="2.1.5"/>
    </quote>
</cit>
```

2. etymological groups:



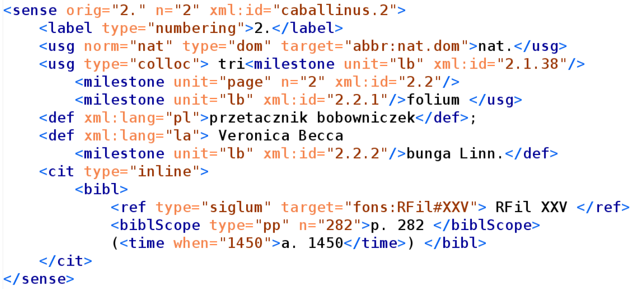
```
<etym>
    (<mentioned xml:lang="la-x-cla">caput</mentioned>
    <certainty cert="low" locus="value"/>?)
</etym>
```

3. PoS and grammar groups:



```
<gramGrp>
    <iType norm="2--i">-i </iType>
    <pos norm="subst"/>
    <gen>m.</gen>
</gramGrp>
```

4. sense groups:



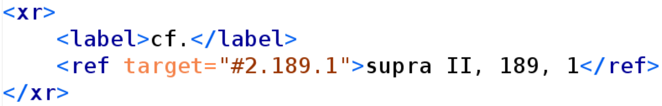
```
<sense orig="2." n="2" xml:id="caballinus.2">
    <label type="numbering">2.</label>
    <usg norm="nat" type="dom" target="abbr:nat.dom">nat.</usg>
    <usg type="colloc"> tri<milestone unit="lb" xml:id="2.1.38"/>
        <milestone unit="page" n="2" xml:id="2.2"/>
        <milestone unit="lb" xml:id="2.2.1"/>folium </usg>
    <def xml:lang="pl">przetacznik bobowniczek</def>;
    <def xml:lang="la"> Veronica Becca
        <milestone unit="lb" xml:id="2.2.2"/>bunga Linn.</def>
    <cit type="inline">
        <bibl>
            <ref type="siglum" target="fons:RFil#XXV"> RFil XXV </ref>
            <biblScope type="pp" n="282">p. 282 </biblScope>
            (<time when="1450">a. 1450</time>) </bibl>
    </cit>
</sense>
```

Enrichment: expanding the dictionary content

Considerable effort was put into enriching the original content of the dictionary, namely: (1) resolving references, (2) normalizing strings, (3) adding redundant and/or inferred information.

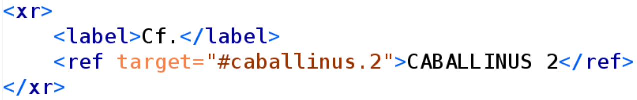
Resolving references

A typical reference to an exact location in the dictionary text was encoded as follows:



```
<xr>
    <label>cf.</label>
    <ref target="#2.189.1">supra II, 189, 1</ref>
</xr>
```

References to a specific entry or sense relied on the **@xml:id** attribute:



```
<xr>
    <label>Cf.</label>
    <ref target="#caballinus.2">CABALLINUS 2</ref>
</xr>
```

The encoding of most frequent type of references (pointing to a source of a language use example) is illustrated in the section II B 4 above.

String normalization

By string normalization, we mean a set of various procedures applied in order to generate a *lexical view* of the dictionary content. Standardized strings are usually stored in **@norm** attributes of such elements as language or usage labels, prepositional and inflectional patterns *etc.* Their primary goal is to enable unified search that would be agnostic of the exact formulation of the paper dictionary. For example, when looking up philosophy-related terms one should be able to retrieve them no matter whether they have been marked with a *phil.* label or with more verbose formula *in textibus philosophicis* "in philosophical texts", as both are annotated as **@norm="phil".** The second major goal of the normalization was to render chronological information consistent and machine-readable. Its proper annotation should reflect the fact that many medieval texts cannot be dated but only approximately. Apart from some obvious cases (`@when` attribute stores a year date, for example **<time when="1450">a. 1450</time>)** the LMILP employs:

1. century dates **(<time notBefore="1401" notAfter="1500">saec. XV</time>)**
2. imprecise dates in year **(<time notAfter="1120">ante 1120</time>**) or century format (**<time notBefore="1401" notAfter="1450">saec. XV in.</time>**).

Making information explicit

Finally, substantial effort has been devoted to making explicit what is not expressed directly in the paper dictionary, but left to be inferred by an expert user. In the LMILP, this is the case, for example, of a part of speech label which is provided for adverbs or conjunctions, but is normally omitted from verb or noun entries. Empty elements have therefore been created and their attributes filled with the inferred content. So, in a typical case, an element **<pos norm="subst"/>** would be appended to a **<gramGrp>** group whenever the paper dictionary informs about a word's part-of-speech only indirectly, by means of a gender label (*f.* for Lat. *femininum*) or inflectional ending typical of nouns (*-ae*):

The Dictionary Web Application

The last part of the paper briefly presents the overall architecture of the dictionary web application, its user interface having been already described elsewhere (Nowak 2014). Written entirely in XQuery, the application is served directly from the eXist-db instance with HTML and JavaScript code being equally stored in a database or generated on the fly. The presentation focuses on those features available in the eXist-db which are of critical importance for dictionary application design:

1. Various types of indexes available in the eXist-db allow for efficient retrieval of content from deeply nested dictionary files and dispersed textual data.
2. A templating system allows for fine-grained web presentation of the XML content.
3. A URL rewriting engine supports a logical system of dictionary content access.
4. An out-of-the-box RESTful API exposes lexicographic content to external applications.

In the conclusion, I will also point to some difficulties that I have encountered and which have mainly to do with handling application's state, a crucial feature for multi-language tools which require storing user search results.

Uncovering ‘hidden’ contributions to the history of Digital Humanities: the *Index Thomisticus*’ female keypunch operators

Julianne Nyhan
julianne.nyhan@gmail.com
University College London, United Kingdom

Melissa Terras
m.terras@ucl.ac.uk
University College London, United Kingdom

Introduction

Who undertook the foundational work of the discipline now known as Digital Humanities (DH)? Whose work merits inclusion in the history of the genesis of DH - the leaders of scholarly projects? Their research assistants? Their administrators? Their funders? Have important contributions to early DH projects gone unacknowledged or been silenced by the field’s dominant ‘founding father’ narratives? How can a better understanding of previously undocumented contributions to the founding of DH allow us to evaluate the centrality of processes like collaboration and interdisciplinarity to the development and establishment of DH?

This paper describes our research on the ‘hidden contributions’ to the *Index Thomisticus* project of Fr Roberto Busa S.J. (1913-2011). Busa is often said to be the founding father of DH: “Most fields cannot point to a single progenitor, much less a divine one, but humanities computing has Father Busa, who began working (with IBM) in the late 1940s on a concordance [the *Index Thomisticus*] of the complete works of Thomas Aquinas” (Unsworth 2006; see also Hockey 2004 and the more nuanced analysis Busa’s role in Jones (2016)). Our research has uncovered the details and nature of the contributions made by the punched card operators who transcribed the (pre-edited) texts of Thomas Aquinas and related authors into machine-actionable data using punched card technology, thus completing the essential preliminary work on the *Index Thomisticus*. The operators were the mostly female trainees of the keypunch school that Busa had set up in Milan in 1956 (and that ran until c.1967) as well as the female keypunch operators who worked with him in his Literary Data Processing Centre (CAAL). In addition to recovering the specifics of their work we have also sought to better understand their personal experiences of working on the project and whether the skills they learned were of subsequent benefit to them. Despite the formidable amount of work that they undertook, and the crucial nature of their task to the project, the identities of these women and the nature of their contributions were largely unknown and unacknowledged until this research was undertaken.

Methodology

Previous research on the history of DH has shown that when used with care oral history can contribute to a grounded history that exposes overarching processes while acknowledging through personal narratives the agency and creativity of a plurality of individuals, and not just the great men and women of scientific advancement (Nyhan, Flinn, Welsh 2015). An oral history approach was again adopted for this project; ten of the female punched card operators who had worked with Busa for various durations between 1954 and 1970 were interviewed.

The interviews were carried out from April 1st to 3rd 2014 in the Alosianum College of Philosophical Studies, Gallarate, Italy. Nyhan was present throughout though the interviews were carried out in Italian by Marco Passarotti (a former student of Busa and Principal Investigator of CIRCSE Research Centre, Università Cattolica del Sacro Cuore, Milan) as Nyhan does not speak Italian. Passarotti was given a set of core questions in advance that drew heavily on Nyhan's wider research for the Hidden Histories project (see, for example, Nyhan and Flinn 2016). The questions were prepared with two aims in mind: that of uncovering the Womens' memories of working on the *Index Thomisticus* project as well as capturing their memories of Busa himself. The core questions were:

- How did you first hear about punched card technology?
- How did you find out about the punched card school?
- How did you secure a place there?
- What training did you receive?
- What kinds of work did you do?
- Was the training you received useful to you in later life?
- Please share a memory of Fr Busa?

It was also agreed that Passarotti should ask other questions as he saw fit, for example, in response to an interesting point that was raised by an interviewee. All interviewees signed a waiver form in advance of the interview that gives permission for their recollections to be published. A grant from the European Association for Digital Humanities (EADH, see the call for funding proposals) was secured so that the recorded interviews could subsequently be transcribed and translated by a Research Associate (Ana Vela), who is fluent in both Italian and English. Nyhan then worked through the translations in order to edit them further for clarity and check them, as far as was possible, for factual accuracy. She subsequently carried out a close reading and qualitative analysis of the interviews in order to identify common themes and telling divergences. This was followed by a historical-interpretative analysis that compared and contrasted the issues identified in the oral history sources with relevant primary and secondary literature. Finally, we wrote the results up as narrative history.

Findings

What emerges from the interviews is an insight into the social, cultural and organisational conditions that the female punched card operators worked under and how they were treated in what was, structurally at least, a male-dominated environment. The interviews contain a wealth of recollections about the following issues in particular:

- The womens' discovery of the training school that Busa set up
- Their entrance test to the school
- Their training and tasks as keypunch operators
- The organisational hierarchy of the *Index Thomisticus* workforce
- Their awareness of the aims of the project and of Humanities Computing and Computational Linguistics more generally
- Their knowledge of Latin
- Usefulness of the training to them in later life
- Their memories of Busa.

For example, regarding the usefulness of their training, it opened opportunities that would otherwise have been blocked to them. A number of them went on to work as keypunch operators on an early machine translation project in the EURATOM Center at Ispra, Milan (On Busa's connection to Ispra, see Busa, 1980, p.86). Nevertheless, the interviews collectively give the sense that the women were seen as a source of low-cost and low-skilled labour. They did not have opportunities to progress from the position of keypunch operator and their training seems to have been the minimum necessary to carry out their roles. Most were not even made aware of the wider significance or aims of the *Index Thomisticus* project. Despite the existence of other research projects like

EURATOM, mentioned above, and that an 'employment path' in the context of research computing was beginning to open up, their potential longer-term contributions to such work were not considered or fostered.

Conclusion

It is almost a cliché to say that DH's collaborative nature makes it distinct and differentiates it from traditional Humanities. However, our research on the *Index Thomisticus* project has prompted us to ask whether claims about the centrality of collaboration to DH are more problematic than they first appear. As we will show, collaboration was the basis on which Busa's *Index Thomisticus* was realised. However, in the 'incunabular phase' (see Rockwell et al. 2011) of DH some forms of collaboration were considered more worthy than others and the contributions of the many female (and occasionally male) punched card operators who did the work of the project were not acknowledged. Until our research, their identities and the nature of their contributions had essentially disappeared from both the historical record and the collective memory of the DH community. This gives rise to a number of interrelated questions that have not yet been adequately addressed by scholarship on the history of DH: when and how did collaboration take on its significance for the field? What has influenced decisions about what kinds of DH collaborations have and have not tended to be acknowledged and how has this changed over time? What is the significance of the alleged cleaving of DH from the practices of the mainstream Humanities in regard to collaboration? Accordingly, our paper will also aim to open a wider discussion about the history of collaboration and the role it played in the formation and establishment of DH.

Trauma Representations in Videogames

Jennifer Olive
jolive1@gsu.edu
Georgia State University, United States of America

Over the last few years, the videogame community has seen an increase in the visibility of indie games, particularly ones that focus on serious subjects. Given the name "empathy games" by Minority Media's Vander Caballero in his 2014 GDC talk, this sub-genre is known for its intense and meaningful narratives that often bring to light traumatic experiences. While the classification of these games under empathy can be problematic as highlighted by Anna Anthropy (2015) and the responses to her game Dys4ia, the phenomenological experience of playing these videogames offers a new perspective through which one can engage understandings of new media aesthetics and narrative design. Moreover, Caballero's (2014) identification of the "empathy game" category as strategic for project support highlights the development of the sub-genre at a point which methodologies of analyzing these aesthetics and design choices as they relate to the representation of trauma within videogames are needed most. Building on the relevance of the issue as well as the unexplored intersections that such mediation brings to prior understandings of critical theory, this paper will propose a methodology for analyzing representations of trauma in videogames that builds on current work in the field. Moreover, it will explore the theoretical implications of such a method to the model of player experience through remediation in order to offer a broader understanding of the meaningful intersection of trauma narratives and new media.

Beginning with its most well-known applications in the 1990s with the work of Cathy Caruth (1995, 1996) in literary studies and in the 2000s with the work of Dominick LaCapra (2014) in history, the study of trauma has spread from its Freudian psychoanalytic roots to become a field of study in both the sciences and the humanities. Both of the models developed by and around these two theorists are extremely helpful for literary representations given their foundations in disciplines that largely rely on print media and are able to be applied to different genres given their multidisciplinary foci; however, the study of trauma representations has not yet spread widely to new media applications aside from its application in testimonial media. This exclusion suggests a gap in scholarship for trauma studies as it does not account for how these models of trauma may be useful in or influenced by other media.

With the increasing cultural and economic impact of videogames, it is essential that the digital humanities develop a critical framework for understanding and analyzing the intersections of trauma studies and videogames. Tobi Smethurst's work (2014, 2015a, 2015b) attempts to bridge this gap by identifying how both game studies and trauma studies could benefit from an interdisciplinary application. Smethurst's doctoral thesis (2015a), explores this intersection to offer a tripartite methodology for analyzing trauma in videogames: interreactivity, empathy, and complicity. This methodology is particularly useful because it examines the rhetorical feedback loop between player and game, which, she argues, creates a very specific experience for representing trauma by implicating the player as a perpetrator, and it works very well for games that are designed to elicit such feedback from players. This methodology, however, does not fully account for videogames being able to represent trauma in ways that do not end in making the player complicit in the trauma.

Expanding on this foundation, my paper will discuss the use of videogames as an interactive digital media platform for representing traumatic narratives, identify a methodology for analyzing such representations, and argue for a model that understands play in videogames containing representations of trauma as a form of witnessing. This work will begin by grounding its understanding of trauma as it is defined in literary studies through the works of Caruth (1995, 1996) and LaCapra (2014) respectively and expanding its theoretical framework to the use of digital media through digital narrative and media studies by exploring the affordances of videogames highlighted by Janet Murray (1997) in Hamlet on the Holodeck. Next, I will discuss a methodology for analyzing representations of trauma in videogames that utilizes those media aesthetics and the object's use of procedural rhetoric as defined by Ian Bogost (2007) in Persuasive Games to create a remediated (Bolter and Grusin, 2000) experience of witnessing as described by Dori Laub (1995) in "Truth as Testimony: The Process and the Struggle." In doing so, I will discuss how this methodology provides a much needed perspective concerning the intersection of videogames and trauma studies. Additionally, I will argue for a model of representing trauma in videogames that seeks to understand feedback loops with the audience in broader terms, which I will ground in the understanding of videogame ethics as discussed in The Ethics of Computer Games (2009) by Miguel Sicart. Such a model will focus on the mediation of the trauma through the videogame experience and account for the overlapping of ethical systems that exist for the player outside of the gameworld, which, I will argue, helps the player navigate the different levels of witnessing. Together, this combination of theoretical foundations will expand on the current scholarship to offer a more holistic understanding of the potential held by videogames as a medium to represent trauma.

Many Tongues, Multiple Networks: A Corpus-Based Pragmatic Study of Multilingualism on Nigerian Virtual Political Space

Tunde Olusola Opeibi
bopeibi@unilag.edu.ng
University of Lagos, Nigeria

Olusola Abiodun Aina
solar_ai2003@yahoo.co.uk
Crawford University, Nigeria

This study examines the increasing utilisation of the Internet and related digital media technologies such as Facebook, Twitter and Youtube for political activities and civic engagement in Nigeria. It however focuses specifically on the ways in which political actors and citizens in Nigeria draw on the existing multilingual resources within the Nigerian sociolinguistic ecosystem in their web-based political interactions.

The study also discusses how these stakeholders use a combination of mixed codes in online interactions with political issues and political stakeholders to reshape the political space and promote participatory democracy.

Theoretical insights that underpin the study adopt approache from **computer-mediated discourse analysis** and **pragmatics.** The data set consists of a range of media multilingual-based online political posts between 2011 and 2015 elicited from our corpus construction project, CONNMDE (Corpus of Nigeria New Media Discourse in English). The methodological procedures also utilise some digital humanities software packages and concordancers such as Sketch Engine and AntConc3.4 for data harvesting and to complement the qualitative and quantitative analyses (Baker, et al, 2008:275).

Generally, the study reports some findings on the ongoing digital humanities project that focuses on new media corpus construction. It then isolates and identifies clear instances of deliberate deployment of multilingual resources influenced by and rooted in ethnolinguistic identities as communication inclusion strategy. It equally confirms that Nigerian politicians use political websites with multilingual texts to encode acts of political persuasion and convey pragmatic meanings.

This presentation concludes by suggesting that online multilingual discursive practices may be indicative of or closely linked to people's purpose-driven offline sociolinguistic practices and identities deployed for socio-pragmatic goals.

Modeling Creativity: Tracking Long-term Lexical Change

Peter Organisciak
organis2@illinois.edu
University of Illinois, United States of America

Samuel Franklin
samuel_franklin@brown.edu
Brown University, United States of America

The concept of creativity underwent a period of shifting meaning and rapid adoption in the twentieth century. Following from a narrow early scope of usage, in which it carried largely religious connotations, the word 'creative' grew broader and adopted the more subjective meanings we are familiar with today. Though many contemporary observers point out the vagueness of the term, creativity's power comes from a particular mix of meanings and connotations accrued over time. Still, there is no clear inventory of the higher-level concepts around discussion of creativity and how they evolved. Additionally, because of the rapid increase in usage, early uses of 'creativity' may be overlooked as they are overshadowed by much more common later uses.

In this paper, we present a method for tracking the different styles of discourse around a concept over time, developed for following the evolution of 'creativity' but applicable to other domains. Our approach is an application of Latent Dirichlet Allocation (LDA) -trained topic models, with three novel steps in their preparation:

- a highly-selective keyword sampling of pages from a large text corpus,
- temporally weighted training sample ordering, and
- purposively-assigned asymmetric document-topic priors.

Motivation

This research supports a larger project on the discourse of 'creativity' in post-WWII America. The anecdotal observation that creativity has become a buzzword in recent years is supported by graphs of word frequency available through platforms such as the Google Ngram viewer and JSTOR Data for Research, which show creativity only entered the American lexicon in the twentieth century, diffusing rapidly after about 1950. 'Creative' appears to have enjoyed a similar growth spurt over the same period, but it preceded creativity by about three hundred years.

Unfortunately, these graphs do not reveal the long-term changes in meaning nor the distinct contexts in which the language of creativity accrued its contemporary salience. It is obvious from contemporary usage that the word 'creative' has a tangle of interrelated but distinct meanings, ranging from *generative* or *constructive* to *artistic* to *nonconformist*. These meanings are distributed unevenly over time and across communities of discourse. To understand why and through what routes creativity arose when it did, it will be essential to tease apart these various meanings of creative, and the contexts in which they have been strongest over the long term.

We believe topic modeling can help. First, it can help us identify and distinguish between the several discourses in which creative has been a keyword—for example in theology versus education versus psychology—whilst still reflecting the historically shifting connections and overlaps between those. Second, we can then apply those topics to only those texts containing the token 'creativity,' to reveal which of the discourses and meanings of 'creative' seem to be at work. By this process we can achieve a more granular picture of the creativity boom, helping us answer the basic question 'what do we talk about when we talk about creativity?'

Approach

Topic modeling enables us to observe more higher-level concepts than keyword searching and collocations would allow. Topic modeling depends on a certain class of mixed model clustering, but we believe that the two should not be conflated. The connotation of 'topic modeling' implies a qualitative interpretability. Surfacing what would be recognized as concepts is not solely a case of running a modeling algorithm on words from a text. Instead, it needs to be paired with a series of preparatory and parameterization steps tailored to the particular problem.

We developed a workflow for training better topic models to track a specific concept in a temporally-biased corpus. This involves standard pre-processing such as stoplisting words, but also contributes three novel steps: selective page-level sampling, weighted training, and explicitly imbalanced prior assumptions on how likely a document is to be reflected by each topic. The sampling helps focus the models on creativity, the weighted training counteracts temporal biases to retain older topics to surface, and the asymmetric priors help find more granular topics.

For a dataset cross-cutting published work broadly, we used a recent release of the HTRC Extracted Features Dataset (Capitanu 2016). The Extracted Features Dataset includes term counts for every page of 13.7m volumes in the HathiTrust Digital Library and benefits from a mostly indiscriminate digitization policy, allowing us to observe a term's usage in a wide spectrum of texts.

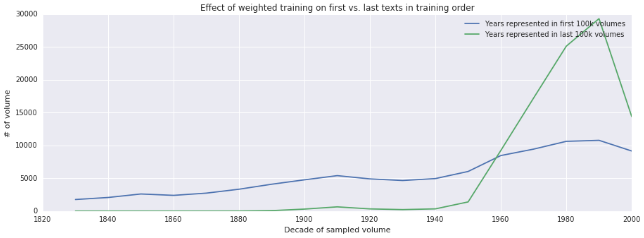
Topic Modeling Preparation

In topic modeling, the goal is surfacing patterns that represent qualitatively intuitive concepts. However, to the *methods* used for topic modeling, the mark of success is being able to represent documents in the desired number of topics with as little error as possible. This divergence between our needs and the machine's makes the text preparation important. One such preparation is to remove words that are not interesting to a human reader. An algorithm may find a meaning in a word like 'however' or 'whereas', but as a proxy for topicality, such words are usually not desired.

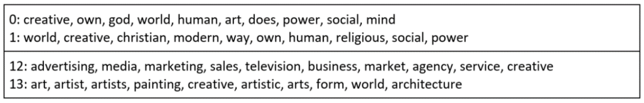
For tracking trends in creativity discourse, we used Latent Dirichlet Allocation (LDA) combined with standard preprocessing: removing the most common words in the English language, less interesting parts-of-speech (e.g. adverbs, determiners, numbers), and cutting off the sparser end of the vocabulary. In addition, we developed three less common preparations in the service of issues arising from tracking concept diffusion.

Sampling. One possible approach to finding the most common topics for a keyword is to look at the underlying term-topic probabilities for the keyword, post-training, and identifying the topics where the word is most common. This approach scales well to multiple keywords but provides low specificity for tracking them. Instead, we sampled only pages that use the word 'creativity' or variants of 'creative'. The size of the HTRC EF Dataset affords the small contextual window and selective sampling, as there were slightly more than 2 million volumes found that have at least a single mention of the keyword list.

Weighted training. When training topic models, earlier texts have an outsize influence on the topics that emerge. This is a problem for our use case, where we expected a topical shift alongside a steep increase in usage. A randomized training order would reflex later texts very strongly, at the risk of missing topics which are prominent in older texts. To counteract this, we applied weighting to the randomized training order, to soften the temporal bias without entirely removing is. When deciding on the next text to send to the training algorithm, texts are weighted for sampling with weight(decade) = 1/ n(decade). The following figure shows this weighting in action: at the important start of training, newer texts are only slightly more common. Since a disproportionate number of older texts are used early on, there are few left by the end of training.



Honeypot topics. As part of the estimation process for LDA topics, we have to formalize our best guess for how likely any given topic is to be assigned to a document. Past work has found value in allowing for these prior assumptions to be uneven - e.g. one topic can be considered more likely than another (Wallach, Mimno, and McCallum 2009). We found initial success with a heuristic intended to find many smaller trends in the collection by provided the first three topics the majority of the probability mass and dividing the remainder between the remaining topics. In qualitative comparisons with evenly distributed probabilities, we found that setting asymmetric priors in this way set traps to catch broadly common documents in predictable topics, while allowing other topics to surface more highly-specific topical hotspots.



0: creative, own, god, world, human, art, does, power, social, mind
1: world, creative, christian, modern, way, own, human, religious, social, power

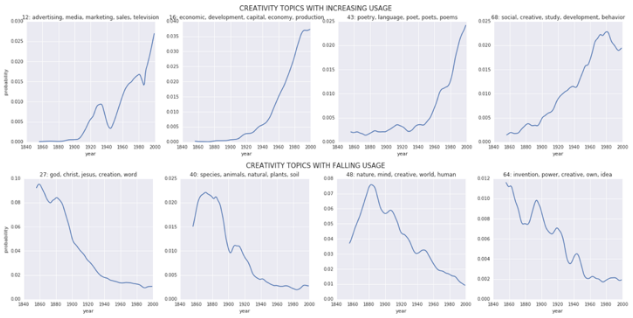
12: advertising, media, marketing, sales, television, business, market, agency, service, creative
13: art, artist, artists, painting, creative, artistic, arts, form, world, architecture

Two general topics and two niche topics

Results

The training yielded several topics which confirm where we would expect to find the language of creativity. Some of these reflect specialized uses, such as in advertising and evolutionary biology, while others reflect the broad humanistic discussions of the nature of thought, art, and religious creation. By graphing these topics over time we can see that our temporally weighted sampling appears to have been successful in revealing archaic topics that are nonetheless essential to understanding the connotative textures of the language of creativity in our own time.

The following figures show a small selection of topics where the usage has grown in the past 150 years, and topics where it has fallen. Generally, we see that the language of creativity has transitioned from religious and natural notions of creation toward the language of economic and human capital.



Future work

This work has a number of future directions. We have thus far focused on a number of words (creative, creativity, creativeness); moving forward, we intend to map how the verb and noun uses compare. Also, while much of the development has been qualitatively development against our particular problem, we hope to compare variants of our workflow in more contexts.

Conclusion

In the proposed paper, we will present our method for tracking longitudinal trends in a diffuse and shifting context. Motivated by work on the language of creativity and particularly the noun 'creativity', our contributions are in text processing and parameterization for topic modeling, allowing clear and specific concepts to be revealed.

Background and General Motivation

The HathiTrust Digital Library

The HathiTrust Digital Library (HTDL) comprises digitized representations of 15.1 million volumes: approximately 7.47 million book titles, 418,216 serial titles, and 5.3 billion pages, across 460 languages. HTDL is best described as "a partnership of major research institutions and libraries working to ensure that the cultural record is preserved and accessible long into the future".

The HathiTrust Research Center (HTRC) develops software models, tools, and infrastructure to help digital humanities (DH) scholars conduct new computational analyses of works in the HTDL. For many scholars the size of the HTDL corpus is both attractive and daunting: many existing DH tools are designed for smaller collections, and many research inquiries are facilitated by more focused, homogeneous collections of texts (Gibbs and Owens, 2012).

Worksets

In many, if not most, DH research endeavours, performing an analytical task across the whole HTDL is neither practical nor productive (Kambatla et al., 2014). For example, a tool trained to identify genre attributes of 18th century English language prose fiction may not be applicable to 20th century French poetry. The first step is to identify the subset -- of works, editions, volumes, chapters, pages -- to set an initial investigative scope and, indeed, subsequent iterative refinements of a subset as research proceeds. In a corpus as large and complex as the HTDL, finding materials and then defining the sought after subset can be extraordinarily difficult.

HTRC has come to call collections of digital items brought together by a scholar for her analyses a "workset", created to help the researcher build, manipulate, iteratively define and compare their collections. Reflecting upon input and advice from the DH community, Jett (2015) defines a workset as a machine-actionable research collection realised as:

1. An aggregation of members (volumes, pages, etc.);
2. Metadata intrinsic to the workset's essential nature (e.g., creator, selection criteria);

3. Metadata intrinsic to digital architectures (i.e. creation date & number of members);
4. Metadata supportive of human interactions (i.e. title & description);
5. Derivative metadata from workset members (e.g. format(s), language(s), etc.); and,
6. Metadata concerning workset provenance (e.g. derived from, used by, etc.).

Broadly, item 1 identifies the actual data used in an analysis; whereas the remaining metadata items describe the workset itself, aiding workset management throughout the research cycle.

Cross-corpus worksets

As alluded above, numerous criteria can be used to select the constituents of a workset; and several technological implementations could, in theory, realise worksets. In researching the design and realisation of worksets and associated tooling, we are also mindful to remain grounded in their practical application and the needs of scholarly users. We have therefore undertaken our work through discipline-based scenarios in which we can explore the strengths and weaknesses of the HTDL viewed through the prism of worksets.

We report one such exploration here, questioning *whether (relatively) small, well explored, and well understood corpora can be superimposed over the HTDL to aid navigation and investigation of the much larger and superficially understood HTDL collection?*

From a system perspective, a cross-corpus workset requires exposing *compatible* metadata (items 2-6 above) from multiple collections, first used to align common elements, and then to assemble worksets. We take a Linked Data approach and achieve compatibility through ontologies, which might initially be bibliographic (and derived from library records) but should be iteratively extensible into the domain of the subject of study.

Examples in early English print

Early English Books Online Text Creation Partnership (EEBO-TCP) is a partnership with ProQuest and over 150 libraries and universities, led by Michigan and Oxford, to generate highly accurate, fully-searchable texts tracing the history of English thought and learning from the first book printed in English in 1473 through to 1700. Between 2000-2009 EEBO-TCP Phase I converted 25,000 selected texts from the EEBO corpus into TEI-compliant, XML-encoded hand-transcribed texts, subsequently freely released in January 2015.

In the work reported here, we have conjoined EEBO-TCP with a HathiTrust subset consisting of all materials described in their metadata as being in English and published between 1470 and 1700.

To ensure a prototype which simultaneously explored the fit of scholars' needs to the technology and exercised the technical challenges outlined in the previous section, we undertook a 'complete circuit' through the datasets (Figure 1). We: (i) ran a consultative workshop to choose investigations which might form the basis of worksets; (ii) used these abstract worksets to identify concrete requirements for the conjoined metadata; (iii) generated metadata from both corpora according to these specifications; (iv) aligned elements from both datasets in an overlapping superset; (v) realised the worksets identified in (i) using this metadata.

Implementation

Figure 1. Overview of the metadata circuit leading to our cross-corpora workset

Motivating worksets

Following the workshop we identified the following workset selections; we describe their implementation in subsequent sections:

- Find all the works, appearing in both datasets, written by Richard Baxter.
- Find works in both datasets published in Oxford.
- Find works published outside of London (where the bulk were published).
- Find works from both datasets published outside of London in the mid-to late 1600s.
- Find all works in the two datasets for authors who have at least once published on the subject of "Political science".
- Find all works in these two datasets for authors who have at least once published works which are categorised as "biography".

Regarding the penultimate workset, it is of particular note that this returns results across both datasets, since our EEBO-TCP import did not contain genre or topic information; this association must be entirely inferred from the semantic links via the technology described below.

Implementation

Metadata requirements and ontology selection

Building on Nurmikko-Fuller et al. (2015) and Jett et al. (2016) we surveyed the addressable resources and the schema expressivity of ontologies that could parameterise these classes of workset. We identified parsable information structures in the EEBO-TCP TEI data, appropriate to the test worksets, and selected ontology terms to encode this EEBO-TCP metadata, ensuring compatibility (or at least, for our purposes, comparison) with RDF from the HathiTrust. The resultant ontology collection - the EEBO Ontology, or EEBOO - includes selections from MODS, Bibframe, and PROV, along with custom elements encoding additional structures (e.g. dates).

Creating EEBOO RDF and alignment with HTDL

Python scripts manipulated TEI P5 XML, then the Karma Data Integration Tool mapped EEBO-TCP data structures into the EEBOO ontology. Particular attention was paid to dates encoded within strings, an example of rich semi-structured data that can be extracted into structured RDF. Links to author records in VIAF and the Library of Congress (LoC), and multimedia pages in the HTDL and 'JISC Digital Books' website, were generated and added. Finally, author names were aligned between the EEBOO and HTDL triples using a reconfiguration of the SALT tool (Weigl et al. 2016).

24,926 EEBO-TCP Phase 1 records were processed, with 22 distinct types of information in the headers, including 6 different ID types and 3 types of date (publication date of historical work, author associated historical date(s), XML publication/editing dates). EEBOO incorporates 7 of these datatypes, and extends into subcategories for author names and date types. EEBOO contains 713 unique places, 6,489 unique expressions of Person of which 3,588 have VIAF and LoC IDs.

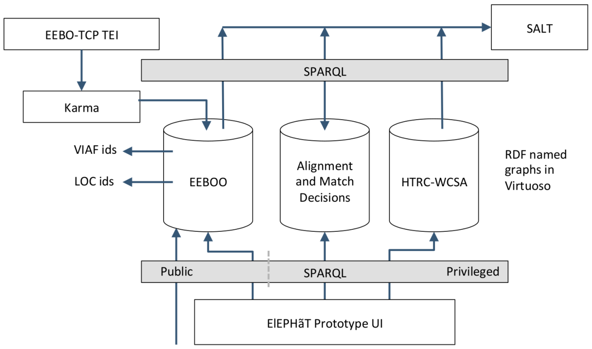

Figure 2. Architecture providing cross-corpus worksets for early English print

Workset construction and viewing

A Virtuoso triplestore (see also, the Virtuoso Github repository) stores the RDF data (totalling 1,137,502 triples) and provides a SPARQL query interface. Figure 2 shows the overall system architecture. The workset constructor user interface (Figure 3) allows the user to select parameters in a web interface which are, in the background, assembled into SPARQL queries used to create a workset. The interface automatically populates valid attributes that are themselves retrieved from the triplestore, using ontological terms having equivalent meaning across datasets. In combination, the generated triples and SPARQL queries are fully sufficient for expressing the motivating workset definitions described earlier.

The workset viewer (also Figure 3) then retrieves RDF workset contents, record metadata, data links, and multimedia links (to the Historic Books collection or the HTDL). Both web applications are written in Python, using the Flask framework, and both rely on the semantic information encoded in RDF and queried using SPARQL.

Conclusion and future work

We have demonstrated the general feasibility of cross-corpus worksets in bringing together HathiTrust content with specialised collections through a specific implementation for early English printed books linking the HathiTrust to EEBO-TCP. Using Linked Data, we see that metadata can be extended in a piecemeal or iterative fashion, potentially moving beyond traditional bibliographic metadata to include semantic structures emerging from scholarly investigation of the worksets themselves; and in doing so support academic motivations and requirements for workset creation.

Acknowledgements

We are grateful to our colleague Pip Willcox for her valuable input and organisation of scholars' workshop, and Jacob Jett for his workset ontology. This work was supported by the Andrew W. Mellon Foundation through the Workset Creation for Scholarly Analysis project award.

Research Objects and scholarship in the digital age

As scientific research practice has grown to include ever greater quantities of data, larger collaborations, and distributed methods, Research Objects (Bechhofer et al, 2013) have been introduced as a means to gather together the context surrounding an investigation and to support its future validation, understanding, and re-use. In many cases these Research Objects build upon the methods, output, and provenance already captured and encoded by workflow systems -- the digital environments in which the science is conducted.

More recently there have been proposals for the use of Research Objects within the digital humanities and musicology (Dreyfus and Rindfleisch 2014; De Roure et al. 2016). Digital editions and annotations of digitally encoded works can be viewed as manifestations of workflows deployed in musicological scholarship, raising the question of how e.g. editorial annotations in a digital score should reference other digital items within the Research Object and vice versa.

For example, a study of the Mariinsky Opera's rendition of Wagner's *Ring* cycle in November 2014 produced a multimedia dataset including audio, annotations made by a musicologist on a short score before the performance (annotations which could be identified a priori from the score such as dynamics, appearances of a leitmotif, etc.), further annotations captured digitally by the musicologist during the live performance (typically staging and interpretive commentary), and free-form text from a digital pen (Page et al. 2016). If the score in use had been a digital edition encoded in MEI (the XML-based Music Encoding Initiative, as reviewed by Crawford and Lewis 2016) how might we reference the musicologist's annotations? Or the other media objects captured and the metadata describing them; existing Linked Data references to Wagner and leitmotifs; and to earlier surveys and studies made by the musicologist on leitmotif interpretation?

Linked notation in support of musicology

Notation examples are a vital part of analytical essays in musicology, helping to illustrate analytical observations and justify hypotheses, arguments and conclusions. They can be excerpts from a score, or custom-made notations which add annotations or comments to the original notation.

Furthermore, the presentation of multiple analogous musical extracts for comparison is often required to support a musicological narrative. *Paradigmatic analysis*, for example, involves passages of music placed one above another such that analogous elements are directly juxtaposed, with gaps left as necessary to ensure that vertical alignment is preserved. Stacked presentation of different scores or different parts of the same score have been used for well over a century, but they quickly become unwieldy and hard to interpret, especially as the number of extracts increases. What is not available in such paper-based approaches is the interactivity that can make complex comparisons between many extracts practical by turning a static presentation into an iterative exploration of digital materials.

In this paper we consider the example of a digital companion presenting the contents of a Research Object studying the interpretation of leitmotif examples from Wagner's compositions, specifically the *Ring* cycle, as they are presented in numerous historical introductions, opera guides, leitmotivic threads and leitmotif lists included in libretto editions and piano scores. The study of the incidences of these particular leitmotif identifications consists of both the gathering of source material and its digitisation and cataloguing, and a musicological study of the potential relationships, influence and evolution between leitmotif interpretations. To enable the extension and repurposing of the identified leitmotif relationships they are structured using an ontology.

Notation examples in leitmotif guides are usually abstractions drawn from a piano score. When reporting findings from this research it is desirable to present and relate the scholarly arguments back to the musicological context within which they are made: from the score excerpts in the source material; and to MEI encodings that illustrate and encode both the examples from which they are drawn and to complete (piano) scores of the overall operas.

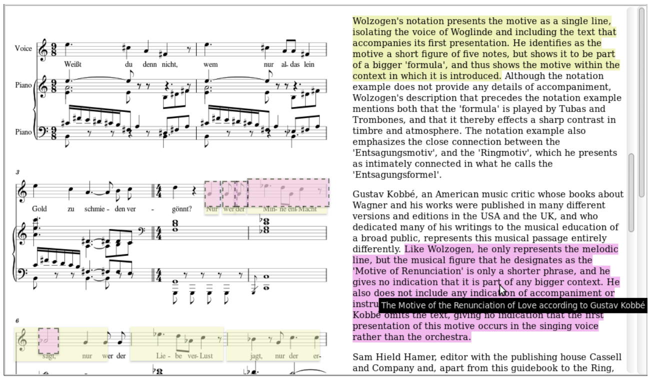
This enables matching and linking of the examples as they are described in the scholarly text, via semantic hyperlinks, to and from the score, including exact matches and variants, illustrating interpretations, and situating the examples back in context. Encoding interpretations in the form of notation examples as variant readings of a certain passage could thereby chart the ‘understanding’ of the work as a history of its variants.

(For example comparing: Richard Wagner, Die Walküre, piano score by Felix Mottl, Leipzig,

Peters, 1914, p.165; Hans von Wolzogen, Thematischer Leitfaden durch die Musik zu Richard Wagners Festspiel Der Ring des Nibelungen, 2nd ed., Leipzig, Schloemp, 1876, p.58, ‘Schicksalsmotiv’; Gustav Kobbé, Wagner's Music Dramas Analyzed With the Leading Motives, New York: Schirmer, 1923, p. 57, ‘Motive of Fate’; George Dunning Gribble, The Master Works of Richard Wagner, London, Everett, 1913, p. 289, ‘Fate Motif’.)

Introducing MELD: Music Encoding and Linked Data

To realise the digital notation companion we have developed the MELD framework (Music Encoding and Linked Data). MELD enables the interactive presentation of multimedia contents of the Research Object, such as the images, text, audio, and MEI encoded music notation described in the previous section. These can be explored contextually alongside each other through the use of semantic links, encoded using RDF, which describe the musicological relationships between the resources (and elements within them). In contrast to earlier technologies which have typically aligned resources against a timeline (e.g. in milliseconds, or using MIDI), MELD expresses relationships anchored to musically meaningful items scoped using MEI. Figure 1 shows a screenshot of MELD displaying text and notation, highlighting leitmotifs as identified in different historical guides.



Voice
Piano
Weißt du denn nicht, wem nur al- das lein
Gold zu schmie - den ver - gönnt?
nur wer der Lie - be ver-Lust

Wolzogen's notation presents the motive as a single line, isolating the voice of Woglinde and including the text that accompanies its first presentation. He identifies as the motive a short figure of five notes, but shows it to be part of a bigger 'formula', and thus shows the motive within the context in which it is introduced. Although the notation example does not provide any details of accompaniment, Wolzogen's description that precedes the notation example mentions both that the 'formula' is played by Tubas and Trombones, and that it thereby effects a sharp contrast in timbre and atmosphere. The notation example also emphasizes the close connection between the 'Entsagungsmotiv', and the 'Ringmotiv', which he presents as intimately connected in what he calls the 'Entsagungsformel'.

Gustav Kobbé, an American music critic whose books about Wagner and his works were published in many different versions and editions in the USA and the UK, and who dedicated many of his writings to the musical education of a broad public, represents this musical passage entirely differently. Like Wolzogen, he only represents the melodic line, but the musical figure that he designates as the 'Motive of Renunciation' is only a shorter phrase, and he gives no indication that it is part of any bigger context. He also does not include any indication of accompaniment or instru

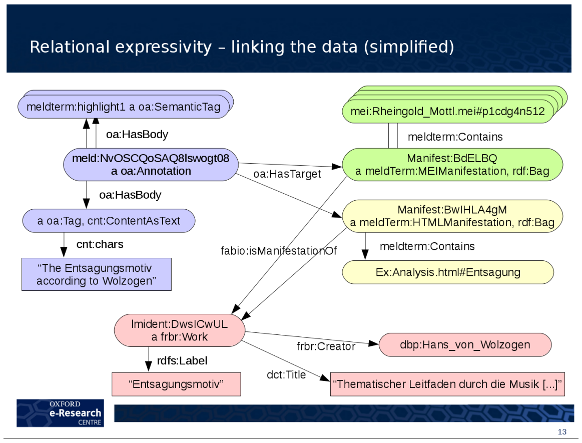
The Motive of the Renunciation of Love according to Gustav Kobbé

Kobbé omits the text, giving no indication that the first presentation of this motive occurs in the singing voice rather than the orchestra.

Sam Hield Hamer, editor with the publishing house Cassell and Company and, apart from this guidebook to the Ring,

Figure 1. MELD displaying contextualised text and music notation.

To render our music notation (encoded using MEI) we use Verovio (Pugin et al. 2013), an open-source MEI renderer that produces beautiful SVG renditions of the score. In addition, Verovio provides an architecture in which identifiers (in other words, anchors for our relational Linked Data expressions in the MEI XML) are persisted through to the rendering (in SVG) which can be connected to identifiers in our contextual information (in RDF). When rendered (and re-rendered) for the user in our web based application interface, the browser uses these identifiers to generate interface elements and undertake actions that combine information from the MEI and the Linked Data.



Relational expressivity – linking the data (simplified)

Figure 2. Musicological relationships, encoded using Open Annotations, within the Research Object (simplified).

Within the Research Object, we treat the XML IDs of elements within the MEI resource as fragment identifiers, so URIs can be straightforwardly generated for each notation element of interest. We employ the Web Annotation Data Model (Sanderson et al. 2017), using these URIs as targets of annotations representing each musicological marking. Corresponding annotation bodies are associated with semantic tags defined to encode the different musicological interpretations, which are in turn the annotation bodies of a top-level annotation targeting the URI of the files currently being viewed, including the music encoding (MEI) and scholarly interpretation (HTML). A simplified example of such relationships is shown in Figure 2.

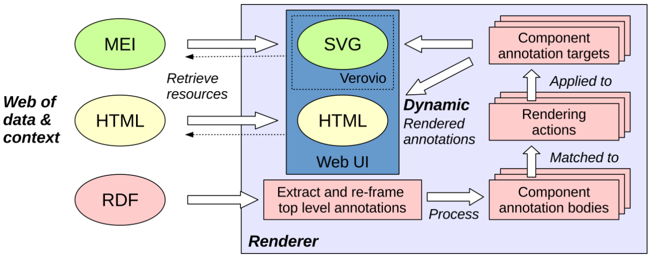


Figure 3. The MELD framework (shading corresponds to that in Figure 2).

The MELD client then uses HTML/CSS and JavaScript, served by a simple web service implemented with Python Flask, and illustrated in Figure 3. The procedure driving the rendering and user interaction is illustrated in Figure 1. The client processes a framed (see the explanation of framing) JSON-LD representation of the RDF graph instantiating the data model. It then performs an HTTP GET call to acquire the MEI resource targeted by the top-level annotation, and renders the corresponding musical score to SVG using Verovio. User interactions are captured using HTML divs drawn as bounding boxes over portions of the SVG corresponding to MEI elements of interest; this is simplified by

Verovio's retention of MEI identifiers in the produced SVG output.

Acknowledgements

This work has been supported by the UK Arts and Humanities Research Council grant AH/L006820/1 'Transforming Musicology', and EPSRC grant EP/L019981/1 'Fusing Audio and Semantic Technologies for Intelligent Music Production and Consumption'. We thank all our colleagues on these projects who have supported and encouraged this work, particularly Carolin Rindfleisch for her complementary work on musicological ontologies, and Laurence Dreyfus for wider inspiration and motivation in developing these technologies.

Twitter as a source for the history of the present : the 2015 Greek referendum as a case study

Sofia Papastamkou
sofia.papastamkou@meshs.fr
Maison Européenne des Sciences de l'Homme et de la Société, France

Introduction

Twitter data have been growingly used as a source for scholarly studies in various disciplines in recent years (Williams et al., 2013). The value of such born-digital data as primary source materials for future researches in history is already being acknowledged (Webster, 2015, Steinhauer, 2015). But, at least for now, historians seem rather reluctant to make use of them, although some recent works deal with the perception and memory of the past on Twitter (Clavert, 2016, Turgeon, 2014) or propose both documentation and analysis of present time events (Ruest and Milligan, 2016).

One possible reason of this reluctance could be the attachment of historians to traditional archival collections, e.g. those organized by professional archivists. But the creation of archives for social network sites data is not yet systematic and still in the beginning. As for the global Twitter archive of the Library of Congress, it is unknown when it will be functional (Zimmer, 2015). As it is possible for one to retrieve Twitter datasets, a second reason of this reluctance could be the need for acquaintance with basic methods and tools for gathering, understanding and analyzing born-digital data. However, not all historians are trained to digital humanities and quantitative methods that provide for such skills. Last but not least, the main reason could be the relation historians have with time. It has always been difficult to define the moving frontier between the present time and the recent past in contemporary history (Bédarida, 2003). As instant ephemera data that belong in the very present time, Twitter data precisely underline the difficulty for historians to define their own territory in these temporalities.

Nonetheless, for historians concerned with contemporary historical events – historical in the sense of a conjuncture that reveals a before and an after (Le Goff, 1999) – Twitter provides an original documentation. This documentation is generated in real time; organized around folksonomies – the hashtags – that reveal a direct perception from below; but also in close relation with media coverage. Since the creation of Twitter, a series of hashtagged global events (#IranElection, #15M, #Occupy, the 2011 Arab revolutions under various hashtags, the 2015 terrorist attacks in Paris...) update the concept of the monster-event (Nora, 1972) in that they are produced, lived, transmitted and shared in real-time around the globe – or at least in its connected parts. In spite of the known biases, mainly the fact that it is mainly used by relatively young and highly educated adults (Pew Research, 2016), Twitter offers an original kind of non-institutional primary sources (tweets) that can be complementary to the traditional ones the historians use.

This paper is a tentative to document and to provide a first analysis, based on Twitter primary sources, of the Greek referendum of 2015. This event has already obtained a distinctive status in the "before" and the "after" the current crisis marks in Greece's post-transition to democracy history (after 1974) (Avgheridis et al., 2015), although time and future historians will definitely tell. The paper considers the transnational phase of this event, which followed the Greek vote in favour of the "no" to further austerity measures, included negotiations in the instances of the EU and ended with the agreement of the Greek government to conclude a third harsh austerity programme. Our main research hypothesis is that the imbrication of different hashtags reveals different temporalities that allow researchers to construct regimes of historicity of an event.

Event background

In the aftermath of the 2008 financial crisis, Greece, an EU and Eurozone member, began going through a severe debt crisis that revealed the structural weaknesses of the European monetary union and soon expanded to other weak members (Portugal, Ireland, Cyprus and Spain). Since 2010, the crisis has been managed through the setup of a European financial assistance mechanism in exchange for national programmes of structural reforms and budgetary cuts. Two such programmes were applied to Greece in 2010 and in 2012, plus a debt restructuring, that were monitored by the European Commission, the European Central Bank and the International Monetary Fund (Papaconstantinou, 2016; Zettelmeyer, 2013). The ongoing crisis provoked profound social and political transformations in the country that brought to power a coalition government led by the radical Left party of Syriza in January 2015. Syriza won the election with the promise to put an end to austerity politics. The party emerged in the context of the post-2008 crisis that shook the countries of Southern Europe and the 2011 Indignant movements, just like Podemos in Spain. Thus, the referendum of July 2015 was far from being significant only in the context of the Greek crisis as an effort of the new government to ameliorate the terms of the Greek programmes, as it put at stake different visions for the EU and its crisis management politics.

Data collection and analysis: method and tools

Tweets using the hashtag #greferendum were collected with NodeXL, an add-in to MS Excel (Smith et al., 2009). The collect was setup once daily from July, 6 to July, 16 2015. The size of the gathered sample was determined by the capacities of the tool, that can collect a maximum of around 20,000 tweets at once. A total of 204,714 tweets were collected of which 139,945 are retweets (68,36 %), 8, 686 responses (4,24 %), 56,086 mere tweets (27,39 %). Minor collects were also launched for other related hashtags (mainly #thisisacoup). Hashtag data were treated with OpenRefine and further explored with R software.

Statistical analysis of textual data (tweets) was made with TXM-Textometry software (Heiden, 2010). The corresponding dataset had been previously encoded following the TEI P5/XML standard with use of the OxGarage service.

Social network analysis and visualizations were made with Gephi software (Bastian et al., 2009).

Data analysis: first findings

Hashtags

The first part of the research focused on reading the hashtags of the dataset. The hashtag #greferendum was used with a variety of hashtags, a total of some 12,000 words (all languages and variants included). A first study focused on the hashtags with a frequency over 99, which gave a total of 158 words. After an elementary typology was established, it was possible to distinguish: geographic names, names of persons, institutions, common names, neologisms that came out of contractions (such as "greferendum"), short phrases that had the function of commentary. The use of hashtags varied between tag and commentary, or included both functions at once (Bruns and Burgess, 2011). The big majority of hashtags are in English (112 out of 158). However, in the thirty most frequent hashtags of the dataset, it is possible to find words in Spanish, Italian, French, and German. By consequence, the linguistic communities that participated in the global interactions were the ones that were the most concerned by the crisis. As for the Greek language, it is not entirely absent as such, but it is mainly present in its greeklish form: Greek words used as hashtags but written in Latin alphabet.

A close reading of the thirty most frequent hashtags with parallel consideration of the associations of words (coocurrencies) shows the tractations that followed the Greek referendum were basically perceived as an intergovernmental affair with the EU actors occupying a secondary position.

An interesting case is the emergence of the hashtag #thisisacoup as an act of solidarity of Spanish militants of *Barcelona en Comú* towards the Greek government during the Eurogroup and the Euro Summit negotiations (12-13 July). The corresponding dataset is more oriented to the expression of personal opinion than the dissemination of information with hashtags in the form of phrases that function more as commentary than tags (such as #yovoycongrecia).

Domains

The most tweeted domains were twitter.com (7,352 tweets) and theguardian.com (7,217 tweets). In general, it is possible to distinguish two main tendencies. First, the dissemination of information in social media (Twitter, YouTube, Instagram, Facebook). Second, the dissemination of authoritative information (international media, specialized independent blogs, personal blogs).

Communities detection

The network of the #greferendum corpus is composed by 103,733 nodes and 204,713 relations. After nodes with a degree higher than 10 were isolated (around 4% of the total), 326 communities were detected with Gephi (Louvain method). These communities need to be further explored, however the first findings for the most important of them show that affinities developed around sources of information (media), political and/or intellectual personalities, professional communities, and also linguistic communities.

Conclusion

The network and the detected communities seem to have been structured around the dissemination of information but also political affinities and/or militantism. However, further exploration is necessary in order to better understand the network structure.

A quantitative analysis of the tweets, with emphasis on the associations between the hashtags, indicate coexistence of different temporalities within the temporality of the 2015 Greek referendum that are principally related to the Eurozone crisis, the associated national sub-crisis, and post-2008 anti-austerity movements. In this sense, Twitter primary sources offer insights from a transnational scale.

L’archéologie du paysage sonore: l’Histoire à portée de nos oreilles

Mylène Pardoen
mylene.pardoen@wanadoo.fr
Institut des Sciences de l'Homme de Lyon, CNRS, France

L’archéologie du paysage sonore est un concept très récent. Elle tend à chercher/pister les traces sonores passées et disparues, tant dans les écrits que dans les visuels et à les restituer. Elle propose un modèle virtuel qui n’incarne pas une vérité scientifique figée mais une proposition représentant l’état de la science à l’instant de sa création et qui est voué à évoluer. C’est donc la restitution d’une possible réalité d’un quotidien passé qui s’appuie sur des critères scientifiquement valides.

L’archéologie du paysage sonore innove à différents niveaux et ses spécificités portent sur :

- L'inter et la transdisciplinarité (association étroite entre les Sciences Humaines et Sociales et les Sciences de l'ingénieur) ;
- La valorisation du patrimoine par le sensible;
- La construction autour du son et une élaboration concomitante visuel/son.
- Elle comporte également des innovations en matière d'édition scientifique :
- nouveaux procédés éditoriaux de type hétérographique ;
- sonorisation de nouveaux médias impliquant la réalité augmentée.

L'archéologie du paysage sonore est une réponse possible pour les musées, les maquettes à destination ludo-pédagogique et culturelle ainsi que tout support à même destination. Son caractère scientifique la distingue du sound design (plutôt axé composition artistique et bruitage (pour le cinéma pour le théâtre).

Et, dans un premier temps, c'est pour satisfaire à la demande spécifique des musées en matière de « mise en sons » que les premières réflexions en ce sens sont menées, après avoir fait le constat que les réponses apportées ne leur donnaient pas totalement satisfaction.

Cette nouvelle branche des sciences humaines et sociales prend ses racines dans les études de R. Murray Schafer et son concept d'écologie du sonore (Le paysage sonore – le monde comme musique, 1977, réédition 2010) et dans celles sur le sensible menées par A. Corbin (Les cloches de la terre, 1994, et plus récemment Histoire du silence, 2016). Cette prise de conscience des spécificités de notre environnement qui forment un paysage sonore est à compléter par une petite étude de J. P. Gutton (Bruits et sons dans notre histoire – 2000). Mais toutes ces études restent à l'état théorique. Or, de nos jours, les technologies issues du multimédia nous offrent la possibilité de passer à l'étape expérimentale et de proposer des restitutions respectueuses de l'Histoire et de ses cadres scientifiques.

S'appuyer sur le sensible, et notamment le sonore, pour valoriser le patrimoine permet de répondre à une demande souvent mal définie des conservateurs de musée ou des services d'archives qui désirent associer un volet multimédia lors de leurs expositions à des fins de rendre moins austère la présentation de leurs riches collections. En effet, à une époque où le multimédia modifie chaque activité de découverte, agissant notamment sur la perception, il devient nécessaire d'intégrer cette dimension du sensible lors des présentations touchant au patrimonial.

Que ce soit dans le cadre d'une restitution de paysages urbains, d'ambiances d'intérieur, ou autres, les problématiques restent identiques. La restitution ou création de paysages sonores historiques pose, d'entrée, des questions fondamentales : Peut-on « entendre » ce passé ? Comment le restituer, le faire entendre ? Quelles sont les difficultés, les limites d'une telle restitution ? Quels sont les matériaux ? Où s'arrête l'acte du créateur-artiste-compositeur, celui du chercheur ? Comment dépasser le concept d'habillage sonore (sound design) et aboutir la restitution d'un véritable paysage historique ? Comment intégrer ces notions relevant du sensible, les porter au public ? Pour quel public ?

La demande muséographique place le concepteur aux confins de la composition, de la musicologie et de l'histoire. Un « simple » habillage sonore (sound design) ne peut, en effet, satisfaire cette demande très spécifique qui entre, également, dans les cadres de la sauvegarde du patrimoine immatériel.

En effet, pour le musicologue, le compositeur ou le metteur en sons, ce travail est inhabituel. Les matériaux ordinaires sont quasi inexistants : pas d'enregistrements disponibles pour les années antérieures à 1870. Entendre le passé implique donc qu'il faut en chercher les traces dans l'ensemble du corpus littéraire (livres, journaux, etc.) ou graphiques. Puis, tenter de le pister dans le temps d'aujourd'hui afin d'en faire une captation. Puis le restituer de manière à le rendre compréhensible et en neutralisant le discours afin de faire acte de témoignage (une narration d'historien et non une œuvre de compositeur, où l'acte émotionnel est important et conduit le discours musical).

Pour le visiteur, l'ambiance sonore ainsi (re)créée doit guider son imaginaire pour l'aider à mieux percevoir, recontextualiser des situations historiques, tout en préservant la réalité historique et le laisser maître de ses ressentis et émotions personnelles : trouver le juste milieu, l'équilibre dans la sollicitation de cet imaginaire pour mieux servir le patrimoine et le mettre en valeur.

Entre le constat ou l'émission d'un besoin et son résultat, se situe le travail de l'archéologue du paysage sonore. Dès les prémices, il faut recueillir un certains nombre d'informations, notamment techniques, auprès des conservateurs afin de cerner au mieux la forme que peut ou doit prendre le rendu sonore. L'expérience nous a montré que de nombreuses contraintes techniques étaient présentes, notamment des contraintes matérielles et logicielles. Parmi celles-ci, l'obsolescence présente un réel frein pour les musées car elle représente un coût financier important. Il devient donc évident de mettre au service des musées, des historiens ou des archivistes une représentation audio qui respecte leurs propres contraintes techniques.

Puis viennent les deux phases de « récolte ». La première nécessite le moissonnage de sources hétérogènes (textuelles diverses et visuelles). Initialement artisanale (faite manuellement), actuellement, nous nous orientons vers la mise au point d'outils d'extraction multisources s'appuyant sur le Text-Mining et la fouille d'image de document (Data Mining), ainsi que l'élaboration ontologies grâce à l'appui de nos collègues des sciences de l'ingénieur. D'autre part, des protocoles seront élaborés pour la phase captation, actuellement plutôt expérimentale. La collecte sonore se fait par captation de sons et d'ambiances réelles – preuve des traces de ce passé dans notre présent.

La dernière phase reste, pour l'instant manuelle. La restitution des ambiances sonores doit « caler » au plus proche du support et de la demande et peut prendre des formes différentes, selon que l'on travaille pour un espace, un support vidéo ou un support maquette. Cette partie du travail prend donc des formes différentes et leur mise en oeuvre empruntent à la fois au cinéma et au jeu vidéo – tout en visant un résultat différent, puisque la restitution se veut ne pas véhiculer d'émotions, mais uniquement susciter des ressentis.

La présentation s'articulera sur les différentes phases d'élaboration. Les présentations sonores seront issues de mes travaux :

- la maquette qui sert de matrice à la recherche (*Bretez II* – projet de restitution de Paris au XVIIIe siècle.). Ce projet relève de la recherche empirique et d'une méthodologie expérimentale ayant pour objectif la mise au point d'un modèle.
- Mes travaux sur les fresques sonores historiques, qui entrent dans le cadre de commandes pour les musées (musée archéologique de la crypte Notre-Dame/Carnavalet, Le Louvre et Versailles) permettent également de nourrir ma réflexion.

C'est l'ensemble de ces expériences qui me permettent d'élaborer mes trames et méthodologies.

Brief Summary

This paper presents an initial prototype of a web-based application for textual scholars. The goal of this project is to create a complex and stable research environment allowing scholars to upload the texts they are analysing and either explore with a suite of dedicated tools or transform them into another format (text, table, list). This latter functionality is especially important for research into Polish texts, because it allows for further processing with the tools built for the English language.

This application brings together the existing applications developed by CLARIN-PL and supplements them with new functionalities. The project is based on a close cooperation between IT professionals, linguists and literary scholars, which ensures that the tools will suit actual researchers' needs.

The main features of LEM include: lemmatization, part-of-speech tagging, text clustering, semantic text classification based on machine learning, and visualisation of its output, generating custom wordlists and lemmatized texts.

Challenge

Digital literary studies seem to be one of the most vividly developing strand of digital humanities. Different analytical systems were proposed, e.g. Mallet, PhiloLogic3 plus PhiloMine, but focused on selected techniques and mostly on English texts. Their language-processing capabilities are limited only to lemmatization and morphosyntactic tagging and they usually require from their users certain programming skills.

In order to address those challenges we have developed a prototype of a web-based system, called *Literary Exploration Machine* (LEM), which does not require installation and programming skills. LEM has a component-based architecture, remains open for expanding components, implements natural language processing on different levels and is planned to support several different paradigms of the text analysis.

Scheme of the system

Components

Word frequencies can be simply computed for English, but not for highly inflected languages such as Polish, which has more than 100 possible word forms of an adjective (however, almost-full sets of distinct forms exist only for some lemmas). In such languages, morphological forms have to be first mapped to *lemmas* by a morpho-syntactic tagger, e.g. WCRFT2 for Polish (Radziszewski, 2013). By applying different language tools, we can enrich texts with metadata revealing linguistic structures.

LEM expands WebSty - an open stylometric system, adopting the following features for text description: segmentation-based (lengths of documents, paragraphs and sentences), morphological (words, punctuations, pseudo-suffixes and lemmas), grammatical classes and categories (e.g. from the Polish National Corpus –see Przepiórkowski et al, 2012– tagset, Broda and Piasecki, 2013) and their n-grams.

This set has been additionally expanded in LEM with the following features, allowing for semantic analysis:

- semantic *Proper Name classes* – recognised by a Named Entity Recogniser Liner2 (Marcińczuk et al, 2013),

- temporal, spatial relation (Kocoń and Marcińczuk, 2015), and selected semantic binary relations (e.g. *owner of*) ,
- *lexical meanings* – synsets in plWordNet (the Polish wordnet); assigned to words and selected multiword expressions by Word Sense Disambiguation tool WoSeDon (Kędzia et al, 2015),
- generalised lexical meanings – meanings mapped to more general synsets, e.g. *an animal* instead of *a cheetah*,
- lexicographic domains from Wordnet.

Rich text description is a good basis for several processing paradigms that LEM is going to support, namely:

- *linguistic text preprocessing* - extraction of language data for further statistical analysis, i.e. computing frequencies as the initial feature values, e.g., of lemmas, tags, word senses, etc.,
- *topic modelling*,
- unsupervised *semantic text clustering* and analysis of characteristic features for clusters,
- supervised *semantic text classification* - trained on the manually annotated texts,
- stylometric analysis - performed with the help of the WebSty system.

Processing scheme

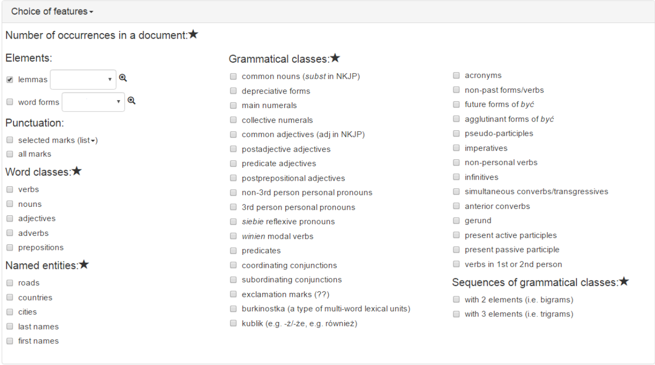
The processing paradigms share the following workflow:

- Uploading a corpus of documents together with metadata in CMDI format (Broeder et al, 2012) from the CLARIN infrastructure.
- Text extraction and cleaning.
- Choosing the features for the description of documents by users (see Fig. 1).
- Setting up the parameters for processing (users).
- Pre-processing texts with language tools.
- Calculating feature values for the pre-processed texts.
- Filtering and/or transforming the original feature values.
- Data mining.
- Presenting the results: visualisation or export of data.

To facilitate the upload, users are encouraged to deposit large text collections in the CLARI-PL dSpace repository. Users are advised to use public licences, but private research corpora can be also uploaded.

OCR-ed documents usually contain many language errors that should be corrected to some extent in the step 2. Moreover, metadata elements (e.g. page numbers, headers and footers) have to be separated during from the content and stored in a standalone annotation.

Users are not expected to have advanced knowledge of Natural Language Engineering or Data Mining. Thus, in Step 4, default settings of parameters will be provided. More advanced users will be able to tune the tool to their needs (see Fig. 1)



Choice of features ▾

Number of occurrences in a document:★

Elements:

☑ lemmas
□ word forms

Punctuation:

□ selected marks (list ▾)
□ all marks

Word classes:★

□ verbs
□ nouns
□ adjectives
□ adverbs
□ prepositions

Named entities:★

□ roads
□ countries
□ cities
□ last names
□ first names

Grammatical classes:★

□ common nouns (*subst* in NKJP)
□ depreciative forms
□ main numerals
□ collective numerals
□ common adjectives (adj in NKJP)
□ postadjective adjectives
□ predicate adjectives
□ postprepositional adjectives
□ non-3rd person personal pronouns
□ 3rd person personal pronouns
□ *siebie* reflexive pronouns
□ *winien* modal verbs
□ predicates
□ coordinating conjunctions
□ subordinating conjunctions
□ exclamation marks (??)
□ burkinostka (a type of multi-word lexical units)
□ kublik (e.g. -ż/-że, e.g. również)
□ acronyms
□ non-past forms/verbs
□ future forms of *być*
□ agglutinant forms of *być*
□ pseudo-participles
□ imperatives
□ non-personal verbs
□ infinitives
□ simultaneous converbs/transgressives
□ anterior converbs
□ gerund
□ present active participles
□ present passive participle
□ verbs in 1st or 2nd person

Sequences of grammatical classes:★

□ with 2 elements (i.e. bigrams)
□ with 3 elements (i.e. trigrams)

Figure 1. Web interface - a panel with a list of features

In Step 5 language tools are run. Each text is analysed by a part-of-speech tagger (e.g. WCRFT2) and next piped to a name entity recognizer (e.g. Liner2, Marcińczuk et al, 2013), temporal expression recognition, word sense recognition (WoSeDon, see Kędzia et al, 2015), etc.

Extraction of features encompasses counting frequencies, but also annotations matching patterns for every position in a document. In the case of wordnet-based features, meaning generalisation is done by iterating via wordnet structure.

A dedicated feature extraction module was built that is similar to Fextor (Broda et al, 2013) but much more efficient by supporting parallel processing. As a result of Step 6 every document is represented as vector of feature values and/or a sequence of language elements.

Filtering and transformation functions comes from the clustering packages or dedicated systems, e.g. SuperMatrix system (Broda and Piasecki, 2013).

Step 8 differentiates between the processing paradigms. Topic modelling, e.g. by Mallet, takes documents represented as lemma sequences. They can be also processed by corpus tools, e.g. for concordances and frequencies. Documents as feature vectors can be processed by clustering systems e.g. Cluto, or used in machine learning, e.g. Weka system.

Different processing paradigms provide varied perspectives on the data, e.g. topic modelling represents a document in terms of stochastic processes generating word occurrences from topic-related subsets in the text. Clustering reveals groups of documents based on content similarity. It is difficult to find a system that supports all paradigms.

In LEM, clustering is expanded with the extraction of features characteristic for the individual clusters. Several functions (from Weka, scikit-learn and SciPy packages), based on mathematical statistics, information theory and machine learning, are offered. The rankings of features are presented on the screen for interactive browsing and can be downloaded.

WebSty, based on elements of the same framework, can be applied to stylometric analysis.

Step 9, visualisation of clustering results (see Fig. 4), is based on Spectral Embedding (also known as Laplacian Eigenmaps). The 3D representation of the data (represented by similarity matrix) is calculated using a spectral decomposition of the graph Laplacian. Texts similar to each other are mapped close to each other in the low dimensional space, preserving local distances.

Use Case

The LEM prototype was developed by the team working with a particular textual corpus of 2553 Polish texts, published in *Teksty Drugie*, an academic journal dedicated to literary studies. The corpus consisted two parts: OCRd scans (1990-1998) and digital files (1999-2014). Given the aim of this paper (software presentation) and the shortage of space, we will treat the results only as examples of the method, without getting into too much detail.

The work on the prototype was divided into stages, conceived as a feedback loop for the developing team: on every stage a new service was added to application and the test run was performed. After the analysis of the result, the step was repeated or the team moved to the next phase.

Phase 1. Cleaning. The OCR-ed corpus has been cleaned (e.g. wordbreaks and headers were removed)

Phase 2. The corpus was lemmatized and parts of speech were tagged. Frequency lists were created what enabled the search for patterns in the textual output. For instance, Figure 2 shows the pattern of interest in particular Polish poets throughout 25 years, based on lemmatized mentions.

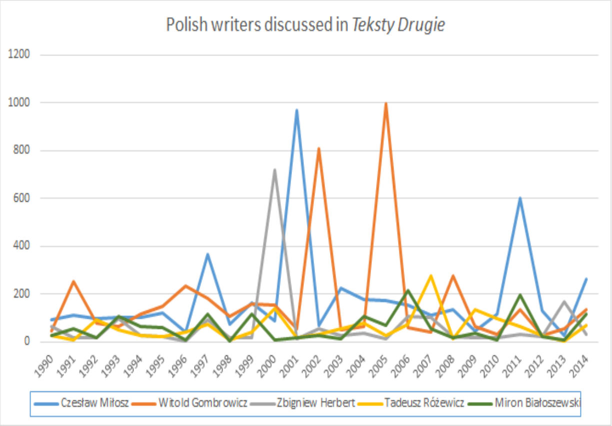


Figure 2. Pattern of interest in particular Polish writers in *Teksty Drugie* (1990-2014).

Phase 3. The analysis of the word frequencies revealed some problems with the word list, especially with numbers, years and city names, which were preserved in bibliographic references. A functionality of adopting a custom stopword list was employed. The exclusion of corpus-specific problematic words and general meaningless words (e.g. a, this, that, if) allowed for visualisation of the most frequent words in *Teksty Drugie* (Fig. 3)

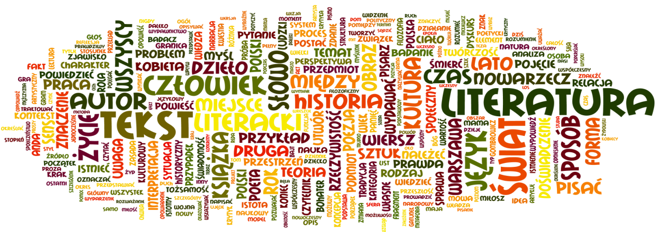

Figure 3. 300 most frequent words from *Teksty Drugie* (1990-2014) (meaningless words excluded) visualised with wordle.

Phase 4. The texts were then grouped into clusters of 20, 50 and 100 in a series of experiments. Each grouping revealed a bit different level of generalization about the texts. LEM, thanks to visualisation features (Fig. 4), allows for real-time exploration of deeper relationships between the texts.

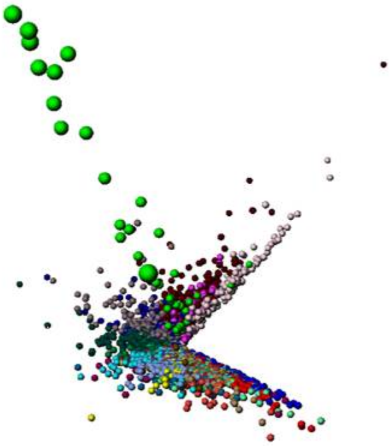

Figure 4. Visualisation of clustering results (weighting: MI-simple, similarity metric: ratio, number of clusters: 20, clustering method: agglomerative, visualization: the similarity matrix converted to distances and mapped to 3D by a spectral decomposition of the graph Laplacian - spectral embedding method).

By choosing the level of granularity (20, 50 or 100 clusters) we may analyse diverse patterns of discursive similarities between texts. Table 1 shows the differences in clustering of the same sample. The first option (20) shows the similarity between texts on a rather general level, that could be described as stylistic or genre similarity (e.g. formal vocabulary). Other options allow for more detailed exploration of general research approach (50) or particular topics analyzed in articles (100). Semantics of clusters is described by the identified characteristic features.

Number of clusters	100	50	20
Cluster size (mean)	25.33	50.66	56.65
Cluster size (median)	24	47	51,5
Smallest cluster size	13	25	2
Largest cluster size	51	91	96

Table 1. Differences between the clustering options (numbers reflect the quantity of texts assigned to particular cluster)

Researchers may explore all options and analyse the vocabulary responsible for classifying particular texts into a certain group by a virtue of being over- or under-represented in comparison to the entire sample.

The LEM is not a real time system. However, processing of the exemplar corpus (2553 documents from “Teksty Drugie”) takes less than 20 minutes. This is due to the use of a private cloud and proprietary message-oriented engine for processing texts. We plan to speed up the process, by running larger number of instances of language tools and by compressing results at each stage. Moreover, the user is able to start processing from any stage, so the processing time is shorter when the user plays with different settings.

Further Development

Currently LEM’s GUI is developed in cooperation with potential users, literary scholars working on various types of texts (fiction, journal articles, blog posts). That is also why we call this software “literary”, because further development will address the issues pertinent for literary theory, exceeding a purely linguistic perspective. Some literary-specific issues and functions will be expanded on the later stage of development, e.g. with adding language tools for Word Sense Disambiguation and partial analysis of the text structure, like anaphor resolution and discourse structure recognition. LEM’s architecture is open for such extensions. With that said, in this paper we have focused on the current stage of development.

LEM will be fully implemented and made available as a web application to the scholarly audience working on Polish. Next, it will be extended with with tools for other languages (e.g. English and German). As LEM has a modular architecture, it would require mostly linking new processing Web Services and adding converters. LEM has an open licences and we will be happy to share our tools, code and *know-how* with teams interested in doing so. Options for exporting to other formats will be added, so that researchers can easily create the output in a particular format (list, text, table) and upload it to other applications (e.g. Mallet) for further processing.

Negotiating Meaning and Value: Institutional Research Assistantships, Digital Projects, and Art History

Julia Polyck-O'Neill

Introduction

Increasingly, art historians, curators, and other arts scholars in an array of institutions—from galleries, libraries, archives, and museums (GLAMs) to the academy—are turning to digital platforms to facilitate and disseminate new scholarship, promote and provide access to collections, and to engage audiences both within institutional spaces and across geographical networks. Our presentation seeks to use our personal experiences working on digital projects in and related to Digital Art History (DAH) as a mode of analyzing and assessing the current state of the field from the perspective of the paid contract worker. As graduate students with minimal formal training in the Digital Humanities (DH), but with an avid interest in developing our theoretical and methodological knowledge, we feel that our contribution to this emergent and continuously evolving conversation is of value to academic researchers planning and undertaking large-scale digital research projects, particularly those who might be hiring and training research assistants. Because we also seek to contextualize some of the issues we have encountered in the intersections (and interstices) between DAH and DH tools and methods, our study speaks to how these align (or resist aligning) within the conditions of academic institutional realities, where we, as graduate students in Art History, are negotiating the differences between traditional and digital approaches to the discipline.

Project Description

In this paper, we examine how these issues manifest in an on-the-ground institutional context: that of the university research assistantship. We seek to analyze our roles as contract researchers on digital projects, while extending the scope of our examination to include some of the wider-ranging issues that came to light during the course of our work. We then suggest a number of viable solutions and best practices in response to some of the problems we have each encountered, and offer observations about how these issues are systemic within the field of Digital Art History, digital collections, and archives in general—particularly those rich in visual materials.

While traditional Digital Humanities methods work in some instances (for text or data mining, the creation and dissemination of certain kinds of archival or library-based catalogues, GIS-related geographical applications, and so on), we note that DAH—particularly where it engages with a specifically material- or object-based approach—requires its own specialized methods, most of which are still emergent or have yet to be developed. Borrowing from Johanna Drucker's writings on the specific needs of art historians working in digital environments, Diane M. Zorich's studies of extant digital initiatives in cultural institutions in the United States, and bolstered by our own direct experience as graduate students and museum professionals, we perceive that much work needs to be done in the field of DAH.

Perhaps even more importantly, we observe that more effort needs to be directed toward making knowledge of effective DAH methods and platforms with DAH-specific affordances accessible within institutional environments that may not have the infrastructure or expertise in place to carry out DH methodologies, and where digital projects are known to have academic capital yet are not effectually supported. It is our hypothesis that these issues, while generally unintentional, are the result of a maladapted atomization of attitudes and methods that were never intended for the disciplinary particularities of projects dealing specifically with visual, aesthetic, and/or material culture; or for the specific needs of broad public-facing institutions such as GLAMs.

Furthermore despite the gradual emergence of highly visible projects concerning the digital study and dissemination of visual materials—projects such as Object:Photo at the Museum of Modern Art, and the Getty Foundation-funded Online Scholarly Catalogue Initiative—these projects are almost exclusively the purview of large, well-funded institutions. At the same time, we have seen some training opportunities for new digital art historians, such as the 2015 Building a Digital Portfolio institute at George Mason University. As productive as these short-term training institutes are, however, scholars new to DAH require more intensive opportunities to develop these skills, something that many art history departments are currently unprepared to provide. Left out of the equation too are small and mid-sized GLAMs, even those affiliated with large universities, which lack the personnel, experience, and funding to pursue rigorous digital projects. As graduate students and researchers, we have seen first-hand how the absence of a robust network to share ideas and opportunities, teach new skills, and develop new approaches can hamstring the full potential of DAH projects. Although there is a clear interest in and need for platforms and methodologies for Digital Art History, in most instances there is not yet a thriving ecosystem to develop and share them.

Conclusions

Although we offer this as a personal, narratological account of our experiences working as research assistants on digital projects (at Brock University, Ontario; and the University of Arizona, respectively), we also analyze how the programming aspects of these projects may be handled in differing institutional contexts—whether researchers are trained in digital applications, out-of-the-box platforms are adopted, or programming and development are outsourced—and examine these practices in light of their compatibility with both the practical and more abstract aspects of our respective endeavors. We will look at how these decisions inform and shape project development trajectories, as well as how they delimit these projects' longer-term potential. Importantly, we will consider issues of accessibility as they concern research assistants, and examine our own limitations in relation to the usability of the tools and platforms at our disposal in our respective institutions. Additionally, we examine how our independent, unpaid projects allow for the extension of boundaries and exploration in the field, and consider the ethical implications of how unpaid work informs and supports our contributions to funded, institution-based projects.

Citational Politics: Quantifying Impact in *Digital Scholarship in the Humanities*

Introduction

Digital humanities has made an important intervention in scholarly communication, particularly in the realm of citational practices. For example, it has facilitated quantitative analysis of citations within humanities disciplines, illuminated the citational networks in play, and led to the creation of workflows and tools for interpreting citations (Romanello 2016; Crymble and Flanders 2013; Blaney and Meyer 2013; Nyhan and Duke-Williams 2014). Such analysis has much to offer how we understand the confluence of citation, power, and privilege within academic communities of practice.

Yet, the lens of citational analysis has rarely been turned towards digital humanities scholarship itself so we might understand the dominant trends in citational practice. Doing so, however, offers insight into both the citational politics that reinforce homogeneous scholarly practices and illuminates the way that gender, race, and nation are understood in digital humanities. Further, we might map the ways that digital humanities citational practice reveals the contours of the field. One of the few truly international fields, digital humanities moves across nations, languages, and institutional structures. What might citational practices teach us about how digital humanists interact and how areas of inquiry within the field are understood across the world? This line of inquiry answers Isabel Galina's (2013) challenge for greater inclusion in digital humanities scholarship by embracing her mandate:

> We have a combination of scholars who can provide important insights to do this properly. Cultural theory, postcolonial studies, feminist perspectives and other forms of critical theory can make us aware of the problem. But DHers' capacity and willingness to build things can allow us to create projects and tools that help us to be more inclusive.

As such, this paper presents the method, results, and implications of our analysis of citational politics in the journal *Literary and Linguistic Computing* (*LLC*), now *Digital Schol-*

arship in the Humanities (*DSH*). Moreover, we use these results to present recommendations for a new politics of citation that encourages increased diversity of thought and method in digital humanities scholarship.

Analyses of citations in digital humanities scholarship are rare. Domenico Fiormonte has taken up these questions in relation to multilingualism. He argues that Anglophone citations are overrepresented, producing a "monoculture" in digital humanities that devalues scholarly contributions from languages other than English (Fiormonte 2015). Stacy Stutsman (2015) has explored the distribution of digital humanities scholarship in pedagogy, suggesting that the same, narrow list of digital humanities practitioners and theorists from the United States and the United Kingdom - Steven Ramsay, Matthew Kirschenbaum, Lev Manovich, Dan Cohen, Franco Moretti, and Susan Hockey - populate syllabi. These studies raise the important question of which factors shape the citational practices of the digital humanities. While Fiormonte tracks monolingualism in scholarship and Stutsman's study indirectly hints at the effect of nation on pedagogy, the influences of nation, gender, and race on citations in digital humanities journals remain a mystery. These concepts are important, however, because of the reputational and academic currency that citations produce and the growing focus on impact for humanities scholarship. As a result, further analysis of citational practices in digital humanities holds the possibility of uncovering which communities are privileged and disadvantaged by citational practices and how this correlates to other ways of conceptualizing the relationship between access, power, and knowledge in the context of digital humanities scholarship, such as geographical divides between Global North and South and representation within the Alliance of Digital Humanities Organizations (ADHO).

To understand the citational politics of digital humanities scholarship, we began by selecting *DSH* as the subject of our study. Although publications from other constituent organizations of ADHO, such as *Digital Humanities Quarterly* or *Digital Studies / Le Champ Numérique*, are open access and arguably have a significant impact on digital humanities scholarship, we chose to examine *LLC/DSH* because it is the oldest of the ADHO constituent organization's journals, represents the broadest international constituency of digital humanities, and, arguably, is the most influential. We scraped data from the journal to create a data set of titles, authors, affiliations, abstracts, and citations of articles in *LLC/DSH* between 2010 and 2016. We supplemented this data by researching the affiliations of scholars represented in the citation data. We recognize that scholars might move institutions, publish in multiple languages, and reside in different nations. However, we argue that scholarship is formed in particular ways within particular contexts at particular moments in time. Further, this data is not intended to offer precise individual data but larger trends in citation practice.

Using this data set, we examined correlations between the following types of data to identify the primary influences on citational practice:

Language of article
National location of author's institution
Gender

The results of this study show that citation practices converge around subfields within the larger category of "digital humanities" and correlate to both national identity and language. We posit that recognizing such citational practice might help to diffuse tensions between the many methods and approaches that are subsumed under "digital humanities." We also suggest that citational differences are apparent due to gender and language. Based on our results and analysis, we offer concrete solutions for redressing the troubling citational politics evident in our data set.

We will also discuss future steps for this project, including expansion of the data set to include scholarship from *Digital Humanities Quarterly, Digital Studies / Le Champ Numérique*, and the *Journal of the Japanese Association of Digital Humanities.* This will facilitate the exploration of the relationship between paywalled and open access journals and expand the results of our present study. We also intend to undertake a survey to identify racial self-identification of authors and enlarge the data set to explore the influence of race on citational practice and the intersecting influences of race, gender, and nation on the politics of citation in digital humanities scholarship.

Micro DH: Digital Humanities at the Small Scale

Roopika Risam

Susan Edwards
sedwards@salemstate.edu
Salem State University, United States of America

Digital humanities practices are often understood in terms of significant scale: *big* data, *large* data sets, digital humanities *centers* (Terras et al. 2016; Kowalczyk et al. 2014; Borgman 2009; Kretzschmar 2009). This emphasis leads to the perception that projects cannot be completed without substantial access to financial resources, data, and labor (Prescott 2016; Hockey 2016; Evans and Rees 2012). While this can be the case, such presumptions serve as a deterrent to the development of an inclusive digital humanities community with representation across academic hierarchies (student, librarian, faculty), types of institutions (public, private, regional), and geographies (Global North, Global South). In response, how can digital humanities scholars find value in work undertaken at a small scale? This question is at the heart of this paper theorizing the practices of micro digital humanities by reporting on initiatives at Salem State University. These practices include the embrace of minimal computing, small data sets, local archives, and freely available platforms for creating small-scale digital humanities projects while working with undergraduate students.

The work of the Minimal Computing Working Group has articulated a vision for minimal forms of digital humanities praxis (Minimal Computing Working Group 2015). Jentery Sayers (2016) has identified key components of minimal computing, including minimal design, maximum justice, and minimal technical language. These principles privilege access and openness for stakeholders across economic and technical barriers. More importantly, they are precepts that envision how digital humanities practices might be available to those who work outside of macro structures that have historically shaped digital humanities. This has been important at Salem State, a regional, public university undergoing an unprecedented budget crisis due to funding cuts from the state legislature. However, we have faculty and librarians who are committed to using digital humanities to cultivate digital and 21st century literacies in our students. As a result, we have conceptualized a micro digital humanities approach inspired by minimal computing. Micro DH validates scholarly output that does not require digital humanities centers, big data, large data sets, and access to high-performance computing. As an intervention in local digital humanities, it places high value on working with available resources, however small.

At Salem State, we have embraced micro digital humanities through our work with undergraduates. This talk explores these practices in depth, as a model for claiming the legitimacy of small-scale digital humanities. It considers how we have drawn on minimal university resources and existing institutional structures to build a digital humanities community.

First, the focus of our work is our university's archives and special collections, a diverse and free but untapped source of material. This choice emphasizes the primacy of local resources in micro digital humanities. Although Salem is known for its history of the Salem Witch Trials and literature of Nathaniel Hawthorne, our archives focus on the common person's experience in Salem from the mid-19th century to present. This includes a rich history of immigration and activism. It exemplifies the power of micro digital humanities for the diversifying the historical record by giving voice to the ordinary and everyday. Through our work, we shed light on the hidden histories that shape Salem today.

We undertake this work in service of our undergraduate students. Micro digital humanities is an approach that cuts across hierarchies in academic labor, bringing faculty, librarians, and students together to create small projects. Salem State is the most diverse state university in Massachusetts (35% students of color, 40% first-generation college students) and draws a primarily regional, working-class student population. Both the students and the university have few resources, but we work with what we have. To serve this population, we developed the Digital Scholars Program, piloted through a small grant from the university. We designed the program to answer the call of the university's strategic plan to foster student success through research opportunities. Students apply to become Digital Scholars, and those who are selected are mentored through the process of creating a small-scale digital humanities project over the course of a semester.

Because they receive course credit rather than payment, we do not believe that we can, ethically, ask students to work on projects for us. Instead, the program is student-centered and student-led through a scaled down approach emphasizing the creation of micro projects. We select collections for the students to explore related to the history of Salem State then lead them through the experience of creating a digital humanities project from start to stopping point. The process includes making discoveries in the archives, identifying research questions that suit their interests, curating materials, envisioning project design, selecting platforms, and creating a final product - and all the iterative dimensions this process entails. Students also have access to professional development workshops and opportunities to engage with guest speakers who are themselves digital humanities practitioners. Projects our students have undertaken include recovering the history of LGBTQ activism at the university, revealing the colonialist gaze of Salem residents who traveled to India in the 1920s, creating historical models of the university's oldest campus building, and connecting contemporary student activism around Black Lives Matter to the history of anti-racist activism at the university in the 1970s. These projects have helped students engage in a range of practices: digitizing texts, TEI, Omeka, 3D modeling, quantitative textual analysis, data visualization, and oral history. In the spirit of micro digital humanities, we only use freely available resources or open source software we can host ourselves. This is a response to our lack of financial resources but is also a result of our focus on students; we do not want to force them to use proprietary technologies they may not be able to afford to access outside of a university or on their own.

We situate this work as a practice of micro digital humanities, cutting across hierarchies to shift students from the position of consumer of digital media and technologies to the role of producer. This requires setting aside our preferences for what projects based on the collections should look like and recognizing that students will be working at a small scale. However, we view these small projects as pieces of a bigger puzzle that illuminates life in Salem. To bring these projects together, we developed an umbrella digital humanities project called *Digital Salem,* a portal that aggregates student projects by collection. Users visiting *Digital Salem* are offered multiple ports of entry into the history, culture, and literature of Salem. There, the small student projects add up as they contribute to a rich, varied resource on Salem. This experience has suggested how a micro digital humanities can be designed with emphasis connecting small projects as modular pieces that work together to form a bigger picture.

These micro digital humanities practices have been the foundation of the digital humanities community at the university. They have brought together faculty, librarians, and students to facilitate student research at a teaching-intensive university. Further, they offer a model for developing digital humanities at scales appropriate to institutional contexts and strategic planning. Perhaps more importantly, they offer a vision of digital humanities with learning curves and barriers to entry that do not require affiliation with centers, access to expensive technologies, or substantial resources. This, we argue, is essential to the development of an inclusive digital humanities community.

A Scholarly Edition for Mobile Devices

Peter Robinson
peter.robinson@usask.ca
University of Saskatchewan, Canada

Barbara Bordalejo
barbara.bordalejo@kuleuven.be
University of Leuven, Belgium

It has frequently been asserted that the digital turn may make it possible to bring scholarly materials, and specifically literary texts, to new and larger audiences than ever before possible (e.g. Jewell 2009). The new breed of mobile device (tablets and smartphones), combining ease of use and powerful interfaces, present an extraordinary opportunity, to make new kinds of books to reach new readers. However, almost all digital books so far made conform to the Erin McKean's characterization of them as "paper thrown on a computer screen": thus eReaders and .pdf files (2007). It is clear that as producers of eBooks, we are achieving less than we could. In this paper, we survey attempts to produce digital works which both reach new audiences and which offer new perspectives on reading.

A few publishers have produced exemplary digital representations of literary texts which have shown, decisively, that digital books can be far more than eReaders and pdfs. The TouchPress publications of T. S. Eliot's *The Waste Land* and Shakespeare's Sonnets, among others, show how reading in the digital medium can be embedded in rich structures of image and sound, extending far beyond the printed page. TouchPress has been extraordinarily successful in reaching huge audiences, reporting in 2012 over 290,000 purchases of its "The Elements" app, and over half a million sales of all its apps (*The Guardian* 2012). The Barcelona-based "Play Creativad" team has shown too with their iClassics publications how much can be achieved with imagination and rather minimal resources. The original release of iPoe has been downloaded more than 500,000 times. These publishers have proved that classic texts may be given new life within the App environment.

These publications have, however, been the exception rather than the rule. Between them, TouchPress and the Play Creativad team have published fewer than ten literary texts. Further, the resources (in the case of TouchPress) and creative ingenuity (in the case of Play Creativad) underpinning these books are in short supply. In this paper, we report on our own attempts to follow the path blazed by these two in our own work on Geoffrey Chaucer and the *Canterbury Tales*. We are acutely aware that we lack both the resources and creative force of our models. On the other hand, we know our text very well, and have scholarly resources to deploy. This paper will describe the CantApp: a new way of presenting Chaucer's *Canterbury Tales*, beginning with the "General Prologue." The CantApp breaks new ground in several respects. It is the first App (an application specifically designed for tablet computers and other mobile devices) to present an authoritative edition of the *Canterbury Tales*, or indeed, to our knowledge, any medieval English text. Second, it will target an audience usually not specifically addressed by scholarly publications: students and other readers encountering Chaucer for the first time. Third, it will present a new reader's text of the *Tales*, based on the work of the Canterbury Tales Project and designed to allow new readers to discover for themselves the *Tales* in the most original form now available. Fourth, while designed primarily for beginning readers of Chaucer, it will be created to the highest scholarly standards, and will incorporate materials usually found only in advanced research-oriented publications, notably Richard North's annotations and explanations. Fifth, and most important: our aim is to use this chance not just to allow students to read Chaucer as they might read him in existing print editions, but to read him in a new way.

We aim not just to bridge the gap between digital editions containing little, but read by many, and those containing much, but read by a few. Our aim is to enable a new way of reading Chaucer. We contend (as have many before us) that the *Canterbury Tales* is a multimedia object containing both visual and aural elements. Visual: in that the poem comes to us from a manuscript culture in which the marks on the page – the ornamentation, the use of emphatic devices, the paratext, the forms of writing – are indicators of meaning. Aural: in that the poem comes alive from the page when it is read aloud and heard, in performance. Accordingly, the central axis of the CantApp is the simultaneous presentation of the key Hengwrt manuscript of the *Tales*, in high-resolution full-colour digital images, synchronized to the sound text, itself very close to the Hengwrt manuscript. Thus, the reader will hear the words, spoken in our best effort at the original pronunciation, with poetic and dramatic expression, with each corresponding line of the manuscript scrolled and highlighted insync, and with glosses, explanations and notes always one click away. All we want to offer is already available on the internet of course: but always at a distance, so that the reader is distracted away from the text. By centring the reader's experience on the sound of the text and the appearance of the manuscript, supplemented as needed, we can bring Chaucer to beginning readers with a rich immediacy hitherto available only after years of study.

As well as presenting our own new reader's text, the manuscript, and performance in sound, the CantApp includes Terry Jones' "minimal translation" of the General Prologue, with his annotations. Jones is uniquely qualified as a reader of the *Tales*: not only by his own formal academic writings, but through the transmutation of Chaucer which has fed his own creative work for nearly half a century. How Terry Jones reads Chaucer, word by word and line by line, is revelatory. Hence, the reader of the CantApp can compare his or her own developing sense of Chaucer with that of Terry Jones. In addition, the creators of the CantApp will provide all the materials the beginning reader will need: annotations, textual notes (with further manuscript images), glosses of difficult words.

It is a conventional wisdom, that – several decades into the digital revolution --traditional print books still remain the best way to read the *Canterbury Tales*, and indeed for any major work of literature. The new generation of digital books, as those mentioned from TouchPress and Play Creatividad, is challenging that wisdom. A key factor is the App environment. Unlike a PDF reader, or the Kindle or similar paper-on-screen systems, a well-made App is not a surrogate for a print book or anything else: it is a new kind of experience. Unlike reading in internet browsers, where any number of factors (unpredictable screen sizes, network failures) may disrupt the reading experience, the App environment permits complete control over exactly what the reader sees, and instantaneous response to reader actions. The key word is immediacy: within an App, the reader may move as surely and rapidly from one part of the publication to any other as easily as one may turn the page in a printed book.

Furthermore, the multimedia possibilities of an App provide opportunities for reader engagement no book can match. The performative aspect of the *Tales* may be directly expressed through the reading we offer, and the line-by-line synchronization of the reading with the manuscript, the edited text and translation, offer an immersive reading experience fed by image and sound as well as words on the page. Our hope is that readers will find themselves as completely engaged with the *Tales*, though in a different key, as could be achieved by any printed book. Indeed, the judicious matching of text and sound with notes and glosses (prepared by Richard North) designed to inform without distracting might offer beginning readers a fast and accessible way into the *Tales*.

The resources needed for Apps constructed according to this template -- images of the original source, a sound edited text, a reading of the text, translation and annotations -- may reasonably be gathered by many scholarly projects. For making the App, we used the well-known, robust and (importantly!) free PhoneGap system, and making the whole required only a few weeks of programmer time (including learning how the PhoneGap worked). Because of these low marginal costs, we are able to make the App available at low cost (not more than 1 euro) or free. We are considering following the Play Creativad model, of selling at low cost most of the time, but with significant periods of free distribution. The measure of our success will be not just how many readers we get for this publication, but the number of other projects which follow this model.

Playful Instruments: Reimagining Games as Tools for Research and Scholarly Communication

Jon Saklofske
jon.saklofske@acadiau.ca
Acadia University, Canada

In academic contexts, digital games are often studied as texts or are used as pedagogical tools to teach basic concepts in early education situations. Less usefully, their systems and economies are often co-opted and decontextualized in short-sighted attempts to "gamify" various aspects of learning or training. It's no wonder that digital games often appear as a marginal endeavor in Digital Humanities practices, despite their relative compatibility with the broad scope of DH methods and perspectives. However, given that games are highly controlled, conditional, choice-and-consequence-based, problem-solving environments in which players are expected to interact with simulated settings and elements after agreeing to take on particular roles and subject positions, there are promising potential uses of these experiences in academic contexts that have not been fully considered.

One of the unique ways that DH provocations and practices have managed to create a critical lucidity is through making, through the construction of prototypes and through discussions regarding alternative models of perception, narrativity, organization and understanding, enabled through the computer's multi-media frame. DH work often defamiliarizes and repoliticizes the forms and functions of communication and scholarly work, and continues to challenge socially constructed and sustained institutional habits by asking "What is the relationship between making, thinking, using and critique?" "Thinking through" tools, prototypes, interfaces and platforms and through the narratives that such processes construct, DH-inspired experiments are slowly, but noticeably and provocatively expanding opportunities for scholarly research and communication methods and means. Such changes are the product of an imaginative resistance to traditional limitations and habitual practices in our institutions.

Motivated by the imperative to explore alternative modes and methods of scholarly research and communication, and guided by the values of open social scholarship practices, this paper reconsiders games not as things to study, but as instruments to study with. Given that games can function as simulations, models, arguments and creative collaboratories, game-based inquiry can be used as a potential method of humanities research and communication. While these ideas have been explored in a preliminary way in relation to a few different academic disciplines (Donchin, 1995; Boot, 2015; Mitgutsch and Weise, 2011; Westecott, 2011) this paper will make the case for a humanities-calibrated consideration of the pragmatics and potentials of game-based research, games as instances of critical making, critical intervention and scholarly communication, and more complex forms of game-based learning than those currently practiced.

This paper is not about shifting the focus of existing game paradigms and practices to more productive and instructional/educational ends (as is often done in "serious game" or "edutainment" design). It is an attempt to challenge textually-dependent scholarship with game-based processes while simultaneously challenging conventional game features and functions with scholarly creativity and textual affordances. In other words, I am concerned with renewing the process of scholarly inquiry in the humanities via game creation and experience, akin to the richness of what Joanna Drucker describes as "diagrammatic process." I have also been inspired by Geoffrey Rockwell's attempt to avoid the term "serious games" while also promoting the idea that developing and playing through games are viable ways of modeling and reflecting on humanities based research activities.

Several examples will be discussed, including the use of the open-source Twine program in my undergraduate and graduate classes as a simple and accessible game-design engine. Twine can be used to construct environments which ask critical, provocative questions, or which attempt to rhetorically persuade players through interactive experience and interpellative role-playing. Anna Anthropy's *Queers in Love at the End of the World*, Porpentine's *Those We Love Alive*, Mattie Brice's *Blink*, Kitty Horrorshow's *Daymare #1: Ritual,* Pippin Barr's *Burnt Matches*, and Zoe Quinn's *Depression Quest*, are examples of Twine being used as an innovative and disruptive game engine. In addition, Merrit Kopas' book, *Videogames for Humans*, thoroughly explores and justifies the diversity of game-based experiments in Twine: "Authors are doing things with Twine that aren't possible with traditional text. And at the same time, they're using interactive media to tell stories that mainstream videogames couldn't dream of telling" (Kopas, 2015: 11). My students have used Twine to engage their peers in alternatives to essay communication, and working together to design such experiences involves them in a collaborative form of critical making. Composing a networked narrative in Twine is akin to constellating and curating not only ideas, but multiple pathways through such ideas. This critical mapping process is as important as the selective routing process experienced by players, who trace particular storylines through the environment.

The usefulness of such methods can be demonstrated through an assignment submitted by Rebecca Wilson, one of my graduate students, who used the creative process of designing a Twine-based experience to achieve the following research goals:

1. To better comprehend the relationship between William Blake's creative process, his biographical context and his prophetic works,
2. To model and critique his complexity through an emulation of Blake's own disregard for temporal and spatial consistency and his transitional unpredictability, and
3. To explore the Twine engine as a site of utopian hope, utopian method and heterotopic tensions (thus responding to and engaging with theoretical ideas advanced by Michel Foucault (1984) and Ruth Levitas 2013)).

Addressing these questions through the methodology of building the gamespace and producing a written reflection on the process is different from the resulting game experience in which players role-play as William Blake, interactively negotiating and determining causal links between everyday experiences, inspirational visions and creative invention. However, both opportunities demonstrate the variety of ways in which games, game engines, and game platforms can be used as instruments for research, scholarly communication and pedagogy. As well, given that Twine's output is an HTML file that can be served online and accessed through a web browser on multiple devices, Wilson's work is now accessible to a much broader audience than an academic paper on the same topic.

Another example of the ways that games can be used as research tools is an in-progress project that is looking to generate feminist game prototypes to facilitate new models, diverse approaches and different narratives to expose war's patriarchal morphology, to provoke a rethinking of militarised masculinity in the real world and the persistence of hyper-masculinity in idealistic representations of war. These games, designed with alternative value sets to distinguish them from traditionally masculine power fantasies are meant to challenge and realign the values that players become reflexively used to perceiving and employing within mediated scenarios of militarisation and armed conflict. The adoption of feminist value-based design challenges habitual idealisations of war, violence and hyper-masculinity in video game environments through feminist perspectives. Multiple and contradictory feminist war game prototypes can be used to disrupt habits of institutional/personal perception and practice and provocatively/performatively engage players with complex issues of violence, gender and media culture. Incorporating feminist values into a game's design creates an intervention that promotes critical lucidity for players.

Identifying the need to confront and challenge traditional habits of head, hand, heart and media representation when it comes to game-based perceptions of war (which can reflect and configure attitudes towards war in general) is not unique to this talk. Mary Flanagan, in "Practicing a New Wargame" discusses the perceptual limitations reproduced by conventional wargames and calls for alternative ways of imagining conflict resolution:

> "We must look to transcend old conflict models, or we risk perpetuating the damaging myth that there are limited ways of resolving conflicts…. It is vital that game scholars, makers and players see these familiar models on a continuum of change, so new play forms that model new solutions to our problems can be invented. Our games are constantly evolving, and this means we all have an opportunity, even a responsibility, to evolve with them and push ourselves to model the world we wish to create." (2016: 706)

Flanegan's call is an important acknowledgement of game design and gamespace as an opportunity to imagine new models. An effort to reimagine, pluralize and critically engage with the ways that we realize and idealize the long history of armed conflict via a critique of naturalized perceptual habits and assumptions directly speaks to the broader need to expose, augment and erode habitual ways of seeing, being, doing and narrating in the humanities.

These initial examples justify the use of games as research and scholarly communication methods, as more than just new media texts to interpret, and aligns them with current DH efforts to use computer technology as interventions to challenge, critique and re-humanize systems, ideologies, and habitual narrativities, to pluralize perspectives, confront complexity and facilitate multiple models of perception and practice. The computer is a flexible tool can be used in diverse ways to broaden our understanding of human culture and to generate inclusive, inhabitable and thought-provoking stories. By foregrounding the values of open social scholarship and engaging with broader publics via mechanical extensions of perception and action, these unconventional approaches work in connective, integrative and expansive ways to avoid modelling humanities scholarship on more conventional game mechanisms and goals that unproductively foreground acquisition, exploration and competition.

Stable Random Projection: Standardized universal dimensionality reduction for library-scale data

Benjamin Schmidt
bmschmidt@gmail.com
Northeastern University, United States of America

Summary

This paper describes a new method for dimensionality reduction, "stable random projection," (hereafter "SRP") distinctly suited for large textual corpora like those used in the digital humanities. The method is computationally efficient and easily parallelizable; scales to the largest digital libraries; and creates a standard dimensionality reduction space for all texts so that corpora and models can be easily exchanged. The resulting space makes a wide variety of applications suitable to bag-of-words data, such as nearest neighbor searches, classification, and semantic querying possible with data sets an order of magnitude smaller in size than traditional feature counts.

SRP is a minimal, universal dimensionality reduction with two distinctive features:

1. It makes *no distinction between in- and out-of-domain vocabularies.* In particular, unlike standard dimensionality reduction it creates a single space that can hold documents of *any language*.
2. It is *trivially parallelizable*, both on a local machine and through web-based architectures because it relies only on code that can be easily transferred across servers, rather than requiring large matrices or model parameters.

These two features allow dimensionality reduction to be conceived of as a piece of infrastructure for digital humanities work, rather than just an ad-hoc convention used in a particular project. This method is particularly useful for provisioners and users of text data on extremely large and/or multilingual corpora. This creates a number of new

applications for dimensionality reduction, both in scale and in type. SRP features could usefully be distributed by libraries as a (much smaller and easier to work with) supplement to feature counts. After a description of the method, some novel uses for dimensionality reduction on such libraries are shown using a sharable dataset of approximately 4,500,000 books projected into SRP-space from the Hathi Trust.

Description of the method

The goal of SRP is to reduce of text of uncertain length to a much smaller fixed- length vector to which the many tools of textual analysis, machine learning, and linear algebra can be applied. The core technique used here for dimensionality reduction is *random projection.* Random matrix theory has emerged in the past few decades as an useful alternative to more computationally complex forms of dimensionality reduction.(Halko, Martinsson, and Tropp 2009) I make use here of the observation that it is possible to project into a space where points as determined purely by sampling randomly from the set [-1,1].(Achlioptas 2003) A true random number generator is not suitable for reproduction. The other core element of SRP, therefore, is a quasi-random projection for every individual word created using cryptographic hashes (specifically, SHA-1).

This allows the method to be defined algorithmically, making it easy to apply to any text. I have written short code libraries to implement the transformation in the three most important language for DH tool development: Python, R, and Javascript. These include a few necessary additional conventions such as minimal tokenization rules, a method for expanding beyond the 160 dimensions provided by SHA, and the byte-encoding of the Unicode character sets.

Comparison to existing methods

The gold standard for dimensionality reduction are techniques that make use of co-occurrences in the term-document matrix such as latent semantic index- ing and independent components analysis. More recent techniques such as semantic hashing can be even faster and more efficient at optimally organizing documents in various types of vector spaces designed especially for particular documents.(Salakhutdinov and Hinton 2009) Another strategy finding recent use in the digital humanities is using an LDA topic model as dimensionality reduction, which produces neatly interpretable dimensions for analysis (Schöch, 2016; Fitzgerald,2016). In both the digital humanities and computer science, scholars frequently use "top-N" words as a good enough approximation of the textual footprint, limiting the dimensions to a few hundred of the most common words in the corpus, producing what Maciej Eder has called "endless discussions of how many frequent words or n-grams should be taken into account" for stylometry.(Underwood 2014, Eder (2015))

These methods suffer two problems that make them problematic as a *general-use* feature reduction. First, the better ones are computationally complex, and quite difficult to perform on a very large corpus. Second, it is difficult or impossible to project *out-of-domain* documents into the space from a standard projection if they contain vocabulary different than the training corpus. This out-of-domain problem presents a particularly great problem for multilingual corpora, because texts that are missing or in sparsely-represented languages will behave erratically in the new environment.

Some other work in the digital humanities and computer science has used hashes, random projection, and other similar methods as an ad-hoc rather than infrastructural technique. SRP can be thought of as a particular species of *locality-sensitive hashing*, another version of which has been used by Douglas Duhaime to identify reuse in poetic texts based on three-letter phrases.(Duhaime 2016). Also related is the "hashing trick" in computer science(Weinberger et al. 2009), which is better than SRP in many ways for the short documents computer scientists frequently study, but takes significantly more memory to store for book-length documents (an edge case in the computer science literature, but among the most important for humanists).

Applications

This reduced space can be put to many of the same uses as a standard bag-of- words model in considerably less space and with the potential for building web facing tools. Among those to be described are:

1. **Duplicate detection**. SRP is quite accurate at identifying duplicate books in a computationally tractable space using cosine similarity, both inside a corpus and across disparate corpora.
2. **Similarity Search**. A prototype web page allows any user to paste in any text; it will hashed on the client side into the standard space, and a server can return in a few seconds the most similar documents. The top entries can function for duplicate detection; the lower ones presenting interesting opportunities for exploratory analysis. A search for *Huckleberry Finn*, for example, finds a large number of other American adventure novels about boys in the American west.
3. **Classification**
   - SRP features perform approximately as well as top-n words (~77%) on a pre-existing task described by Ted Underwood, separating high- from low-prestige poetry.(Underwood 2015)
   - A single hidden layer neural network trained with 640-dimensional SRP features can accurately classify a held-out sample of books into one of 225 Library of Congress Classification subclasses (for example, whether a work is PR: British Literature or PS: American Literature) with ~78% accuracy based on about 1 million training examples. A single classifier works in multiple languages simultaneously; its determinations on arbitrary pasted

text are accessible for inspection through a web site.

- A different single hidden layer neural network trained with SRP features and a novel encoding scheme for years using Google's TensorFlow framework can accurately predict the years for withheld books with a median error of four years from the true publication date.

SRP as Access

SRP fits in the DH2017's theme of "Access" in two ways.

First, it makes many forms of text analysis on huge digital libraries far more feasible for scholars without access to high performance computing resources. On large corpora, data storage and dimensionality reduction can be more resource- intensive than the actual analysis. The dimensionality-reduced dataset for the full Hathi Trust corpus can fit into 10 GB, easily storable on most computers; subsets are suitable for use in classroom or workshop settings.

Second, the ease with which it works with distributed web architectures, and its language agnosticism, can create new routes into neglected portions of large archives, particularly those with insufficient metadata.

Contested Memories: The Battle of Mount Street Bridge (BMSB), funded by the Andrew W. Mellon Foundation as part of the Humanities Virtual World Consortium, is an online and annotated digital reconstruction in Unity 3D of a seminal battle of the Irish Easter Rising of 1916. A goal of the project was to leverage phenomenologies of time and space as afforded by virtual world technologies to provide new insights and help to answer what had heretofore been intractable questions about how the battle unfolded. The battle, as well as the 3D reconstruction, received a great deal of attention during the Centenary of the Easter Rising, including the specially commissioned radio documentary (Documentary on One, RTE Radio 1) *Battle at the Bridge*.

Building on the interest in and success of this project, the project team was encouraged to further develop the project so that it could be used in secondary schools. Due to the exigencies of technology in Irish classrooms, including limitations on booking lab time with many computers too old to run the VR software, it was decided that a different approach would be taken. Hence the BMSB Augmented Reality mobile app was developed (figure 1), to educate students about the facts of the battle, while providing a deeper and more holistic understanding of war and its effects. At the same time, it provided the project team with the opportunity to leverage digital humanities research within a participatory engagement setting to reach out to second level students and teachers to provide them with opportunities of engaging with cutting edge technologies integrated into a student-led learning environment.

This project shares a philosophic approach with other maker projects in the Digital Humanities, as Sayers et al. (2016), quoting Neil Gershenfield, describe in *A New Companion to Digital Humanities* as "the programmability of the digital worlds we've invented" applied "to the physical world we inhabit" in which objects "move easily, back and forth, in the space between bits and atoms." Thus Augmented Reality (AR), a technology that superimposes digital content, including images, animations, and annotations, over the real world, was decided on as the key technology to translate our research into a classroom setting. Previous research on the affordances of AR for teaching and learning have highlighted that interactivity, collaboration, problem-solving, and narratives mediated through technology can aid both engagement and understanding (Dunleavy et al., 2009). Several AR applications have been developed for primary and secondary education for fact-based topics, such as geometry, astronomy, chemistry, and the human body (see for example Chromville Science; Anatomy 4D; Elements 4D. However, AR applications for humanities subjects are limited. To the authors' knowledge there is no history-based AR application that is designed for use in the classroom, although there are several mobile-based student-centred AR for outdoor historic sites (see for example: Schrier, 2005 for the Battle of Lexington and Singh et al., 2014 for the Christiansburg Institute).

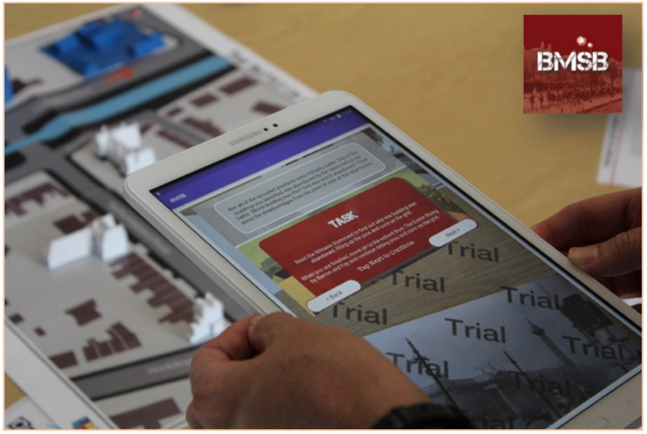

Figure 1. Early prototype of the BMSB Augmented Reality app

These kinds of technologically-driven blended-learning applications which improve digital literacy are seen as the key to the future of education, not only in Ireland, but abroad (see the Digital Strategy for Irish Schools, 2015-2020). Their employment might help to solve challenges such as personalised learning, keeping education relevant, and blending formal and informal processes (Johnson et al., 2016). This project also resonates with the call for a change in history instruction; from one that promotes passive consumption of facts to that which makes more use of analogue and digital primary sources to foster historical thinking (Tally and Goldenberg, 2005; Lee et al., 2006; Stripling, 2011), teaches historical reasoning (van Drie and van Boxtel, 2007), and provides the opportunity to problematise different sources, evaluate arguments, and form new interpretations (Borton and Levstik, 2004).

In terms of app design, the project team were aware of the challenge of how technologies have shifted our attention from the physical to the digital space: interactions with devices absorb attention, distracting from physical experiences and social interaction (Chrysanthi et al., 2012). Therefore, a premise of the project is that, if digital technologies are to assume an active role in history teaching and learning, ways to actively engage students by creating conditions that blend the physical and the digital through participatory and hands-on engagements need to be employed (figure 2).

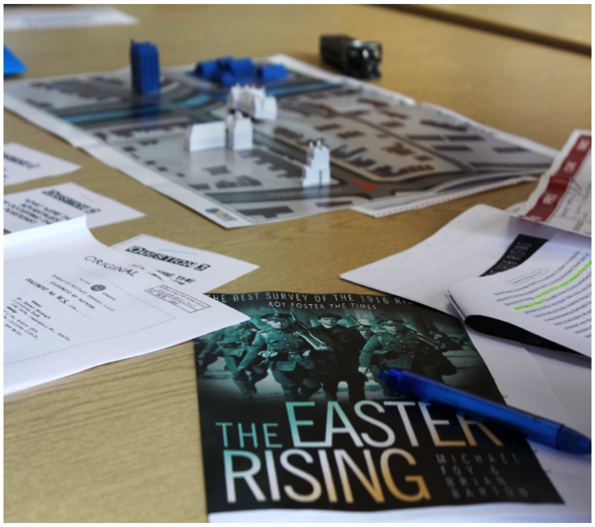

Figure 2. Physical Materials used in 'Lesson 1 - Group 1: The Buildings

The BMSB AR app (developed for Android tablets using the Wikitude Software Development Kit for Android Studio) employs a phygital approach by enabling a task-based digital and AR exploration triggered by physical objects and primary sources, including photographs, witness statements, 3D printed buildings, and state records (figures 2, 3). Since these have a central role in the lessons, students have to evaluate their content, origins, authority, and reliability and finally through group work to form their own interpretations.

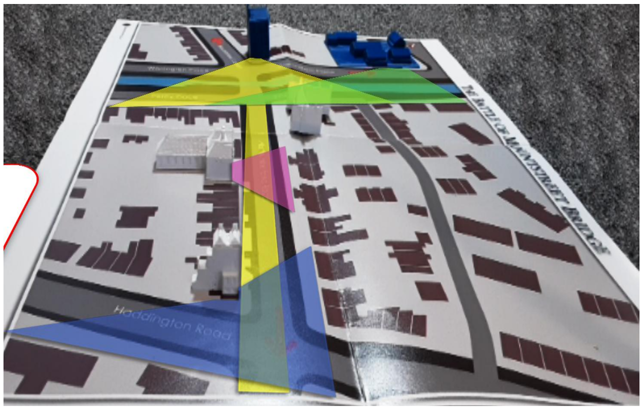

Figure 3. AR element of the app showing over the physical map the lines of fire from the four buildings that were occupied by the Irish volunteers

This project followed an iterative design methodology. The first two focus groups were carried out with second level history teachers (figure 4) to ascertain a) logistical information about schools (e.g. wireless, class size, classroom arrangement, labs etc.), and b) how to develop content and design interactions in order students to get the most out of this experience. The results of the focus group made it clear that due to the wide variance in technology in schools across Ireland, the project had to follow the paradigm of handling/ activity boxes in museums (Comer, 2014) in which everything the teacher needs would be posted, including the tablets, physical materials, and lesson plans for a period of two weeks.

Figure 4 Second Level history teachers testing the AR app during a focus group in August 2016

This paper will report on the different stages of development of the AR app, the difficulties encountered as well as strengths of the approach. It will also describe the results of the testing and formal evaluations carried out with secondary school students and the next stages for the release of the prototype across Ireland.

The Role of Digital Humanities in Countering Cultural Genocide: the virtual reconstruction of Julfa Cemetery

Harold Short
haroldshort@mac.com
Australian Catholic University, Australia

The trail of destruction of cultural monuments in the Middle East in recent years has instigated or given renewed energy to concerns about threatened or destroyed cultural heritage and the use of technology in restoration and preservation. Beginning with work of Armin Grün and his colleagues on the Bamiyan Buddhas, crowd-sourcing of photographs and the use of photogrammetry to construct 3D representations has become an important method of enhancing existing archaeological data in preservation and reconstruction of cultural monuments that are at risk or have been destroyed. Current work of this kind includes - but is by no means limited to - the Rekrei initiative of Matthew Vincent and Chance Coughenour, and the Center for Cyber-Archaeology and Sustainability directed by Thomas Levy, based at University of California San Diego but established as a consortium also involving UCLA, UC Berkeley and UC Merced.

The case of the Armenian cemetery at Julfa, near the ancient city of Jugha, is somewhat unique, because in the century prior to its final destruction access was very restricted, so archaeological research was not possible, and there are rather few – and certainly no 'tourist' - photographs to draw on. At the beginning of last century, there were 10,000 tombstones in the cemetery, including a very large number of ornately carved cross stones ('khachkars') that are unique to Armenian culture. The cemetery was completely destroyed by Azeri troops in 2005-2006, and the site converted into a military shooting range.

What we have as the basis for a reconstruction project are an archive of 2,000 photographs taken very systematically in the 1970s and 1980s by a remarkable Armenian scholar Argam Ayvanzyan, about 500 photographs taken on glass negatives in the early years of the 20th Century, and nearly 50 tombstones that were removed from the cemetery over the course of the century, providing us with valuable direct evidence.

The roots of Armenian culture can be traced to the establishment of Nakhichevan during the Fourth Century BC in what is now the Nakhchivan Autonomous Republic, an exclave of Azerbaijan. Nakhichevan's name derives from the Armenian "Nakhnakan Ichevan" (landing place), referring to the place Noah landed his Ark after the biblical deluge. It was in Nakichevan that Mesrob Mashtots first created the Armenian Alphabet and opened early Armenian schools. The centre of Nakichevan's culture was the ancient city of Julfa (or Jugha), destroyed by order of Shah Abbas in 1605 during one of the periodic wars between Persia and Turkey. The Shah's scorched earth policy did not require the destruction of the cemetery, so it survived.

Until 2005, Julfa cemetery graced the banks of the river Arax with 10,000 tombstones and other funerary monuments, including over 2,000 ornate Armenian khachkars (cross-stones) from the 15th and 16th century, inscribed with Christian crosses, suns, flowers and climbing plants. Alongside Julfa's khachkars stood heavily inscribed ram-shaped stones, unique to this cemetery, and ordinary tombstones. Spread over three hills on Nakhichevan's border with Iran, Julfa cemetery was home to the largest (and probably the earliest) collection of Eastern Christian cultural monuments in existence.

In 2005 Azerbaijani authorities demolished Julfa cemetery's priceless khachkars with bulldozers, loaded the crushed fragments onto trucks and emptied them into the river Arax. Shortly thereafter, Nakhichevan authorities constructed a military shooting range on the very ground where thousands of human remains lie, now unmarked.

In 2013 a small research team was established, seeking to ascertain whether sufficient primary sources still existed to make possible a large scale digital recreation of Julfa cemetery. The results were published in the ebook "Recovering a Lost Armenian Cemetery", which can be downloaded from the project webpage at (https://julfaproject.wordpress.com/). Based on this work, the Julfa Cemetery Digital Repatriation Project was launched in 2015. It aims to return to the Armenian people the entire medieval section of Julfa's cemetery, consisting of 2,000 khachkars and ram-shaped stones. These destroyed monuments are now designated by UNESCO as 'intangible world heritage'.

In further field work in 2015 and 2016, in Armenia, Iran and Georgia, the project team took over 50,000 high resolution digital photographs and 3D scans of the extant tombstones – i.e. those removed from the cemetery during the 20th Century. These were used to create an initial immersive 3D exhibition, which was shown for the first time in Rome in September 2016. Further shows are planned in Australia and North America by the time of the DH2017 conference, with additional khachkars added as the work on the photographic archive proceeds.

The Julfa Cemetery Digital Repatriation Project is hosted by Australian Catholic University at its North Sydney campus, and is a project of the Institute for Religion and Critical Inquiry. The purpose of the project is to create a virtual reconstruction of the cemetery, with the aims of ensuring the public memory of Armenia's cultural heritage, not only for the benefit of Armenians but also as an important contribution to world cultural heritage. The project will also restore a measure of dignity to the 10,000 deceased inhabitants, whose graves now lie unmarked beneath a shooting range. The project will also safeguard an important testimony to early Christian history in the Near East, and to Armenian-Persian and Christian-Islamic relations over a period of centuries.

The project's primary goals are six-fold:

- to create an extensive archive of materials related to the cemetery and its monuments–photographs, documents and digital materials, to be housed at Australian Catholic University and the State Library of New South Wales in Sydney;
- to carry out research and create a basis for ongoing research, not only in Armenian history, religion and culture, but in the history and culture of the wider region, including Persia/Iran;
- to create permanent virtual reality installations in Yerevan and Sydney (and any other city that wishes to have one);
- to create a touring exhibition that can travel to cities without the resources to establish a permanent installation;
- to create a vivid web presence, including online virtual reality exhibits, open to comment and contribution to everyone who may be interested;
- to work in collaboration with other projects and individuals interested in the preservation and reconstruction of destroyed and endangered cultural heritage.

The main source materials are over 2,500 original photographs of the site dating from 1915 until the present, illustrated manuscripts, handwritten journals, architectural sketches and audio recordings. The installations and other outputs will be derived from the repository of research materials gathered and created by the project—archaeological, historical, cultural, theological.

One distinguishing feature of the project is that in addition to ambitious 3D visualisations and realisations, research is being carried out on the carvings and inscriptions. The symbolism of the carvings is important in Armenian theology and cultural history. In addition, each khachkar was created for an individual (or occasionally an event), and the project is researching the inscriptions in order to identify as many as possible of the individuals (and events) they commemorate.

The reconstruction of the cemetery is of particular importance to Armenians, who see its destruction as part of a pattern of cultural genocide in the Near East, and the project has received considerable support from Armenians not only in the country but in the many diaspora communities around the world, including Sydney. There is much wider significance, however. The cemetery was on the border between Armenia and Persia, and the photographic record demonstrates considerable Persian / Muslim influences in the design and carving of the stones. The history of the cemetery is important, therefore, as Iranian as well as Armenian history. In addition there is the wider consideration that all cultural heritage is world heritage.

(Note: a key reason for the project being based at the Australian Catholic University in Sydney, Australia is that the Armenian diaspora in that city numbers 45,000, with many of the families living there able to trace their ancestry back to the Armenians forced by Shah Abbas to leave the ancient city of Julfa prior to its destruction, and to travel with his army to the city of New Julfa, which he constructed near his capital, Isfahan.)

One of the key challenges the project is facing is to do with the 'politics' of cultural memory. Whose interpretation of Armenian – or Iranian - cultural history should be represented? How can differing perspectives on the symbolism of the carvings be reflected? Engagement with a global 'audience' is a key commitment of the project, but how can such engagement be managed in a practical manner that respects the viewpoints and 'rights' of all who wish to contribute?

The political dimensions of repatriating conflict-destroyed sites and the 'human rights' aspects of the project are among some broader questions around the role of digital humanities scholarship in addressing cultural genocide and social injustice. How explicit should such motivations be, especially given that questions of cultural genocide are always contested?

Related to these questions, the paper will also consider how the Julfa Cemetery project stands in the landscape of the many other projects now at work on the reconstruction of threatened or destroyed cultural heritage, and the opportunities for collaboration, not only in relation to technical methods, but perhaps even more importantly in relation to the social, political and regional issues that are common to them all.

Can VR Survive Peer Review? Cultural Challenges for 3D Research

Lisa M. Snyder
lms@ats.ucla.edu
UC Los Angeles, United States of America

Alyson Gill
agill@umass.edu
UMass Amherst, United States of America

In the concluding days of the 2016 session of the NEH Advanced Topics in the Digital Humanities Summer Institute on Advanced Challenges in Theory and Practice in 3D Modeling of Cultural Heritage Sites held at UCLA, participants, faculty, and invited scholars focused discussion on the critical issues facing academics working with 3D content. The goal of these conversations were three-fold: 1) to clearly articulate the challenges facing researchers integrating 3D tools and methods into their scholarship, 2) to outline key questions and new lines of inquiry for future investigation, and 3) to develop actionable recommendations to position 3D work as a valid – and viable – mode of knowledge production. This paper describes that process, the topics chosen for discussion, and the resultant list of action items for the 3D community.

Hapax: Probabilistic part-of-speech tagging in XQuery and XForms

C. M. Sperberg-McQueen
cmsmcq@blackmesatech.com
Black Mesa Technologies LLC, United States of America

Many programs perform part-of-speech (POS) tagging on texts [Leech et al. 1983, Booth 1985, Church 1988, DeRose 1988, Brill 1992, Leech et al. 1994, Schmidt 1994, 1995, Toutanova et al. 2003]; although they use a variety of algorithms, their interfaces tend to be similar:

- They work in batch mode, not interactively.
- They generally model text as a flat sequence of characters; for most, XML markup must be removed before data are submitted to the tagger, and afterwards merged back into the output.
- They are consequently unable to exploit information in XML markup — for example, that “Brown” is here a proper noun and “Essex” there a place name.
- They tag each word token in the input with their best guess at the correct POS; by default, they do not distinguish low- and high-probability guesses.
- They cannot accept partially tagged input. In consequence, the human annotator cannot help them by providing hints on some words.
- They operate on words, not smaller segments.

This paper describes an XQuery-based POS tagger designed to differ from existing taggers in all of these ways. It works interactively one sentence at a time directly on XML (by default, TEI-encoded) text, exploits relevant markup, provides not just the most probable tagging of the input but several ranked alternatives, accepts partially tagged input, and can work on user-specified segments (e.g. TEI w [word] or m [morph] elements) instead of only on space-delimited tokens. Because the tagger described here is designed to support semi-automatic (or 'half-automatic') POS annotation for XML data, it has been given the name Hapax.

Hapax has been designed and implemented as part of the project "Annotated Turki Manuscripts from the Jarring Collection Online" (ATMO), supported by the Henry R. Luce Foundation; the author thanks both the Luce Foundation for their support and his colleagues in the ATMO project for their collaboration.

Design considerations

Early POS taggers used morphological and other rules to assign POS tags to input; later experience showed that purely statistical methods like hidden Markov models (HMMs) could achieve better accuracy with less effort; for tutorial descriptions of HMMs see Rabiner 1989 and Charniak 1993.

For batch-mode POS tagging, accuracy and speed are obvious desiderata. Many modifications, refinements, and alternatives to HMMs have been proposed; these can improve accuracy by several percentage points. Larger training sets make a much larger difference. Schmid 1994 reports a comparison in which the least and most accurate taggers differ by two to four percentage points, while accuracy rates for small and large training sets (< 10,000 and > 1,000,000 words) differ by twelve to sixteen points.

For Hapax, intended to support human annotators working on under-resourced languages, raw speed is unimportant. For any tagger, the human annotator will need to correct many proposed taggings; the key to improving annotation speed is to make corrections faster.

Selecting the correct tag from a menu requires several interactions: the 80 tags in the Brown Corpus POS tag set do not fit into a single menu; many tag sets are larger. Accepting a proposed tagging for a word requires a single user-interface interaction (e.g. clicking "OK").

So speed improves with accuracy: the fastest corrections are those not needed. But high accuracy requires large training sets, which under-resourced languages lack by definition. Some algorithms cope well with limited data. In the Brown Corpus, 92% of all tokens are tagged with the most frequent POS tag for their word type. A trivial 1-gram tagger, which just assigns the most frequent POS tag for each word form, will thus do almost as well on known words as more sophisticated algorithms. In reality, not all words are known, but a 1-gram tagger trained on as little as 2000 words from the Brown Corpus will tag 60 to 70% of input tokens correctly. Larger training sets (8000, 32000, 128000, 500000 words) again do better (68-78%, 73-85%, 77-90%, 82-92%).

Also, we can make tagging errors less costly to fix. If the tagger provides one tag for each segment, every wrong guess costs a manual tag selection. If the tagger proposes several POS tags, then some errors will be as cheap as a correct tagging: one mouse-click. So the goal of Hapax's design is to minimize the need to select tags from menus, by proposing not one but several POS tags for each word.

If a 1-gram tagger for the Brown Corpus proposes not one but three POS tags, the correct tag will be among those proposed 71-80%, 79-86%, 84-93%, 87-97%, or 90-98% of the time (for 2000-, 8000-, 32000-, 128000, 500000-word training sets). If five tags are proposed, the correct tag will be proposed 79-88%, 87-92%, 91-95%, 92-97%, or 94-98% of the time.

If a single user interaction can accept a proposed tagging for the entire sentence, we will save one interaction for each word of the sentence. Hapax uses a standard bigram HMM to calculate the N most likely taggings for the entire sentence. The higher N is set, the greater the chances that only a single mouseclick will be required, but more time will be needed for reading and considering the proposals; it is likely that there is a point of diminishing returns.

XQuery implementation

Hapax is implemented as a library of XQuery functions. One set of functions reads the training material and produces XML word- or POS-frequency lists from them. These list word types or POS tags by frequency, subdivided by POS tags or word types (or, for bigrams, POS of following segment). Additional functions calculate probability distributions for use with unknown words, using the technique of Charniak et al. 1993.

The 1-gram tagger consults the word/POS frequency list and returns the N most likely POS tags for the given word form. The bigram tagger consults the bigram and POS/word lists and uses the standard Viterbi algorithm to calculate the most likely path through the trellis of possible taggings for a sentence. A simple modification of the algorithm allows Hapax to calculate not one path but the best N paths, with time linear in the number of tags in the trellis.

Testing routines generate random test and training sets from a corpus stored as an XQuery database; in a project setting, the training sets are not created on the fly but prepared in advance and stored in a database.The primary interface for consumers of the Hapax library is the function hapax:tag(), which accepts as arguments:

- An XML element representing a sentence
- An indication of what frequency data to use
- Optionally, a set of access functions

The function calls the 1-gram and bigram taggers and returns an XML document describing possible POS taggings for the input. In the common case, the input sentence is a tei:s element, containing tei:w or tei:m elements to be tagged. Input elements may have type attributes; such a partial tagging of the sentence will affect the probabilities for the POS tags for other elements. The optional set of access functions allows Hapax to be used with non-TEI markup; the user-supplied functions are used to identify words in a sentence, detect POS tagging in the input, and add POS tags to the output.

The entire Hapax library is a few thousand lines of XQuery; the rich sets of data structures (including XML as a native type), higher-order functions, and grouping constructs in XQuery and XSLT make the implementation of POS-tagging algorithms remarkably straightforward.

XForms interface

In the ATMO project, Hapax supports a browser-based user interface specified with XForms. The form displays a document, providing an Annotate button for each sentence. When the button fires, the form sends the sentence to the Hapax back end and uses the response to build a form for accepting or changing the annotation. The most likely taggings for the sentence are shown, each with an Accept button. A "Tag word-by-word" button is also shown; in word-by-word annotation, each segment in the sentence is displayed with several proposed tags: first those in the full-sentence taggings, then other common tags for the word type, and a worst-case "Tag manually" button which exposes the POS menus. The user can tag one or more words and activate a "Re-annotate" button, which re-submits the sentence to the back end. This allows the user to explore the effect of one POS assignment on POS probabilities for nearby words.

Within the ATMO project, data must also be segmented and spelling-regularized; those topics and their interaction with POS tagging are not discussed here.

Further work

Hapax v1 uses standard 1- and 2-gram HMMs for POS tagging (Charniak et al. 1993). Future versions should implement Schmid's binary-decision-tree method (1994, 1995), which helps with sparse data. More challenging will be adapting the directed-graph model of Xuehelaiti et al. (2013) to probabilistic POS tagging. This two-level model would allow the probability of a given stem's POS tag to depend not only on the POS of the immediately preceding morpheme(s) but on the tag(s) of the preceding word stems, which may improve tagging accuracy for agglutinative languages.

The Early History of Digital Humanities

United States of America

Most commentators locate the origin of digital humanities (DH) in humanities computing of the mid-20th century. Dalbello (2011), for example, begins her account in 1946 with Roberto Busa's plans for the Index Thomisticus, a massive attempt to encode nearly 11 million words of Thomas Aquinas on IBM punch cards. This event (and the narrative that follows) is found throughout the literature, leading some to believe that early DH work "concentrated, perhaps somewhat narrowly, on text analysis (such as classification systems, mark-up, text encoding, and scholarly editing)" (Presner 2010, 6). Others seem convinced that DH is still only text analysis—and misguided in its approach (Fish 2012).

This paper presents an empirical perspective on the early history of digital humanities by tracing publications in two foundational journals (*Computers and the Humanities*, established in 1966, and *Literary and Linguistic Computing*, established in 1986), with particular emphasis on media types and authors' disciplines.

Background

Despite the variety and breadth of definitions of DH (e.g., Gold 2012 and Terras 2012), narratives of its history have been surprisingly homogenous. Hockey (2004) and later authors (Svensson 2009, 2010, 2012; Kirschenbaum 2010; Dalbello 2011) all ground DH in mid-20th century humanities computing, a view that is all but orthodox in short and anecdotal histories of the field. According to this narrative, DH begins in 1946 with the Index Thomisticus and proceeds through advances in corpus linguistics to the founding of the journal *Computers and the Humanities* (*CHum*) in 1966. These early projects are hindered by storage capacity, hardware costs, and processing limits; progress is slow. Though Svensson (2009) admits that not every article during this time is about text analysis, he notes that the field had narrowed enough by 1986 for *Literary and Linguistic Computing* (*LLC*) to supplant *CHum* as the premier humanities computing journal (note the journal titles). Hockey similarly describes the 1970s and 1980s as a period of "consolidation" of text analysis methods. As storage and processing capabilities increased from the late 1970s onward, structured electronic text and multimedia archives dominated the field, followed in the 1990s by Internet-enabled hypertexts, digital libraries, and collaborative editing. The overarching theme of this narrative is text, with the plot revolving around corpora of increasing size and susceptibility to machine analysis.

Though this account dominates historical views of the field, it raises four separate concerns. First, it privileges certain disciplines, projects, and tools at the expense of others (e.g., quantitative history, which is absent from the narrative). Second, it fails to chart an actual historical path from early work in text analysis to "big tent" DH (Jockers & Worthey 2011; Pannapacker 2011a, b), encompassing everything from digital archives and databases to GIS, network analysis, new publishing formats, digital pedagogy, and so on. Third, it precludes historicizing and contextualizing current work that falls outside of text analysis, which may lead to a lack of attention to method, its historical complexities, and points of convergence with related fields such as the social sciences. Finally, these histories all suffer from a lack of evidence; the narrative is assumed and applied rather than documented.

An alternative approach would attend to the various methods, platforms, and tools that animate current DH work and investigate their origins in the literature. Ball (2013), for instance, has drawn attention to longstanding interest in computers and technology within writing studies. Scheinfeldt (2014) has pointed to the historical importance of oral history in the history of DH. Significantly, Nyhan, Flinn, and Welsh's (2013) project, "Hidden Histories," collects and archives oral histories from those who worked in the field during its first decades. These efforts are in broad solidarity with the empirical history presented here and contribute to the growing number of heterodox histories of DH.

Methodology

The corpus for this study consisted of 1,334 research articles published in *Computing and the Humanities* (1966–2004) and *Literary & Linguistic Computing* (1986–2004). This end date reflects the final issue of *CHum* and predates wide circulation of *A Companion to Digital Humanities* (2003), which was important in shaping DH in many ways. We omitted introductions, reviews, conference reports, and other articles that did not primarily present original research.

We manually inspected each article for media type and applied one of six categories (e.g., text, image, sound, object, number, other). For articles that addressed more than one media type, we recorded 'multimedia'. After inspecting several hundred articles, we added 'technology' as a media type to accommodate articles primarily about technology (e.g., AI, databases, hardware), rather than its application to a particular media. Using all eight codes (see Table 1), we coded or re-coded all the articles.

Category	**Example article topics**
Text	markup for full-text publishing; database of the works of Pascal; use of software for teaching literature
Image	digitized map of land register of 1822; database of manuscript images
Sound	programs for reproduction of sounds; correcting errors in musical databases; analysis of pronunciation
Object	machine classification of features of archaeological objects; techniques for dating medieval inscriptions
Number	database of wages, money, and prices; report on statistics programs; using Mark IV to extract quantitative data from charters
Multimedia	digitizing *Beowulf* (manuscript images and text); recording live performance; video and speech generation
Technology	artificial intelligence; computer-assisted language learning; mainframe and microcomputer file formats; MS Word 3.0; PF474 string co-processor
Other	report on a center; advancements in publishing; reasoning with natural language

Table 1. Media types coded in this study

In addition to media type, we recorded information about each author's discipline(s) and country of institutional affiliation. In the case of faculty appointed to more than one department, we recorded the discipline as 'multiple,' reasoning that an interdisciplinary appointment is more than a simple conjunction of its constituent departments. For authors located outside of traditional academic departments, we used one of three codings, where appropriate: 'center', 'non-academic', or 'GLAM' (galleries, libraries, archives, and museums). The remaining cases were clustered into one of 21 broad disciplines spanning the humanities and other areas.

Finally, we recorded whether each article had a focus on teaching and learning (e.g., courseware, language learning software).

Data on media type, disciplines, and teaching and learning were visualized using the free software Tableau Public and are available online.

Findings

The number of articles published each year varies from 6–50 (see Fig 1), the latter owing mainly to a double issue of *CHum* published in 1994/1995, which we recorded as 1995 because of its copyright date. Given the varying number of articles per year, we report several figures below as relative percentages each year (relative to the total number of articles that year). In cases where the two journals are compared, we also report relative percentages (relative to all articles from that journal in the corpus) because there are nearly twice as many total articles from *CHum* as compared to *LLC*, given their years of coverage.

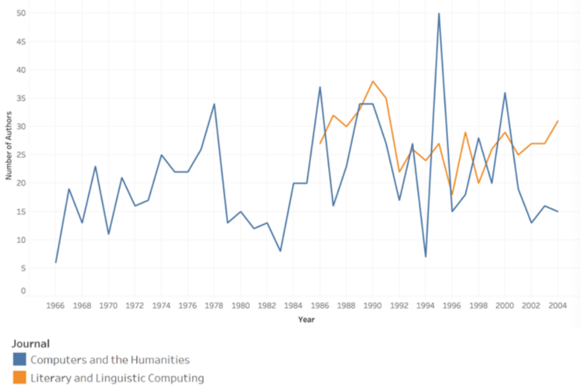

Figure 1. Number of articles published per year

Media type

Text is the most frequently studied medium (59% *CHum*, 72% *LLC*), but sound, multimedia, and reflections on technology are all present in the early literature (see Figs 2–3). These distributions vary by journal, with text being much more prominent in *LLC*.
'Other' is, admittedly, a rather large category at around 4% overall, but the heterogenous articles found there are not easily resolved into one or more media types, which is the focus of these codings, or even a primary theme, such as 'technology.' To some extent, many of these articles speak to the emergence of a field with its own meta-level discussions about theory and the production of knowledge. These articles are found throughout the early literature of DH and increase slightly around the end of the corpus, when "digital humanities" as such might be said to emerge.

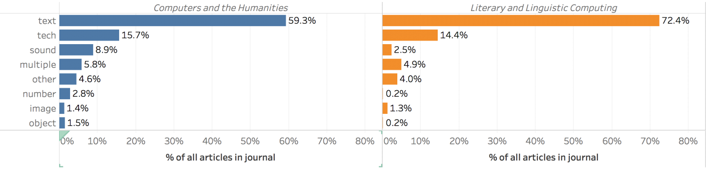

Figure 2. Articles by media type

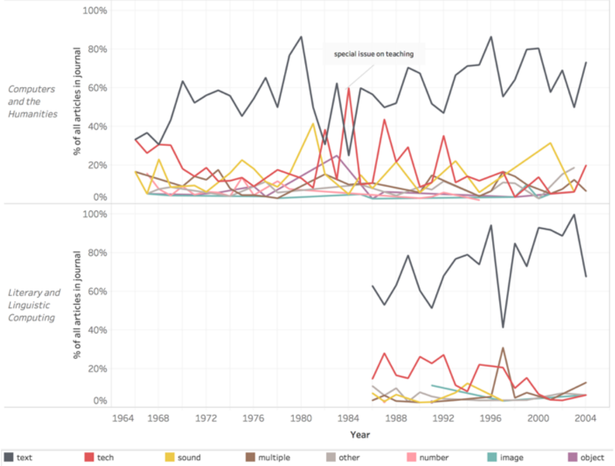

Figure 3. Articles by media type over time

Disciplinarity

The distribution of authors' disciplines present in each journal is shown in Fig. 4. Computing and computer science is most frequent, largely because of the amount of coauthors from those areas. English language and literature is the most frequent humanities disciplines, commensurate with Kirschenbaum's claim that DH's "professional apparatus…is probably more rooted in English than any other departmental home" (2010, 55). However, authors from languages and literatures departments other than English are nearly as common, as are centers, labs, and non-academic affiliations.

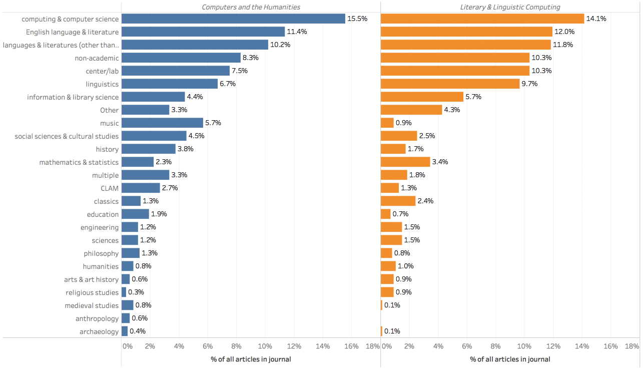

Figure 4. Articles by discipline

Some disciplines work with certain media types more than others (see Fig 5). For example, scholars of languages and literatures work almost exclusively with text, while art historians appear to favor multimedia.

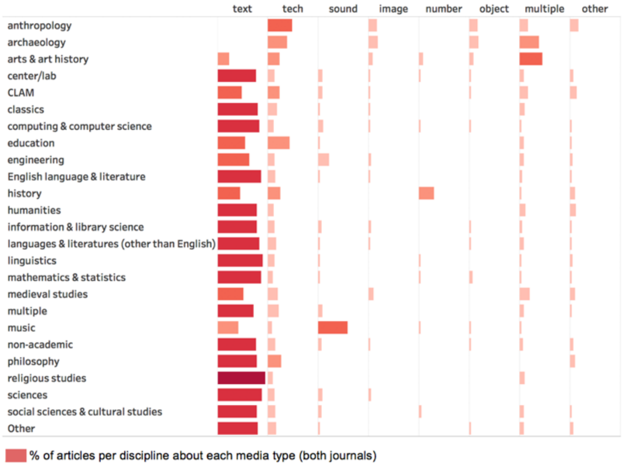

Figure 5. Media type by discipline

Location

Together, *CHum* and *LLC* represent nearly 50 different countries based on authors' institutional affiliations (see Fig 6).

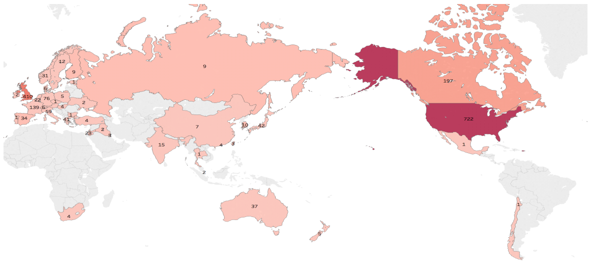

Figure 6. Location of authors

A small but appreciable portion of articles (5.6%, 75 articles) are international (i.e., with co-authors from institutions in different countries). However, the vast majority of authors in *CHum* and *LLC* hail from American and British institutions (respectively), though this predominance declines over the course of both journals (see Fig. 7). This data, as well as the largely Anglophone nature of these journals, presents a limited picture of early DH. A fuller analysis would include work published in other places and languages.

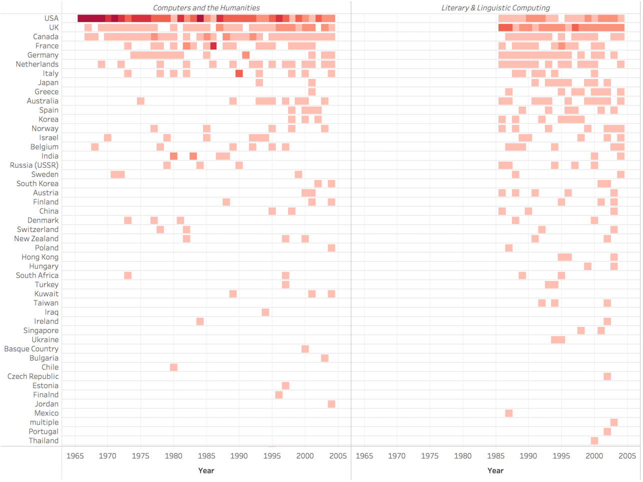

Figure 7. Location of authors over time

Teaching & Learning

There has been longstanding interest in teaching and learning in the field (as shown in Fig. 8), though less so within *LLC*. Peaks in each graph reflect special issues on teaching and learning published by each journal.

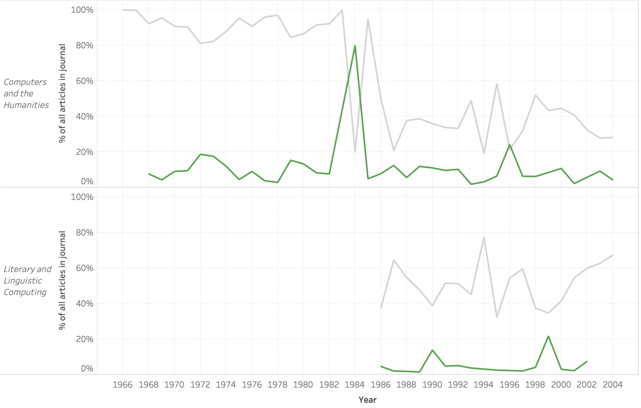

Figure 8. Articles about teaching and learning

Discussion and Future Directions

Rather than focusing on select disciplines, projects, tools, etc., this study includes the full range of early DH work (to the extent it appears in our corpus). The breadth of this picture helps set up the "big tent" view found in current accounts of the field. It also gives ground for historicizing and contextualizing the myriad forms of DH work today. One can imagine exploring this data to discover early DH articles about sound, in classics, from France, etc. and then consulting those primary source articles. Our study does provide some evidence for the claim that early DH work involves text experiments. Significantly, however, it documents the actual extent of that work (59% *CHum*, 72% *LLC*), and in so doing, highlights other work in the early history of the field.

Our next steps include exploring additional sources to expand our corpus. In part, this includes investigating disciplinary journals for early DH articles. We might also identify such articles or journals by mining citations in our *CHum*/*LLC* corpus or by consulting sources such as the

Companion. There are existing lists of early DH books as a starting point for monographs.

In addition, the full text of our corpus presents several possibilities for analysis, including a citation study that might address questions of transference between disciplines and the degree to which corpus articles cite each other (forming their own scholarly discourse) as compared to literature outside of core DH journals.

Humanités Numériques et Web Sémantique : du langage naturel à une représentation computationnelle structurée et sémantique des données

Pascaline Tchienehom
pkenfack@u-paris10.fr
Université de Paris 10, France

Résumé

ModRef est un projet du laboratoire Labex "Les passés dans le présent" qui accompagne divers projets sur des problématiques relatives aux humanités numériques (Oldman et al., 2014). Le projet ModRef s'intéresse spécifiquement au web sémantique (Berners-Lee et al., 2001) et aux données ouvertes et liées. Le but de ce projet est de réaliser une migration de données hétérogènes vers des triplestores encore appelés entrepôts ou collections de fichiers RDF afin d'améliorer le partage, l'échange et la découverte de nouvelles connaissances. Pour ce faire, la norme CIDOC-CRM (Boeuf et al., 2015) a été choisie car elle est actuellement la norme de référence pour la description sémantique de l'information muséographique ou d'héritage culturel (Hooland et Verborgh, 2014). Cette norme permet de décrire les caractéristiques globales des objets (identifiant, type, titre, matériau, dimension, note) mais également leur historique au travers d'évènements ou d'activités (origine, transfert de garde -localisations anciennes, localisation actuelle-, conservation) ainsi que les relations qui existent entre objets ou parties d'objets (bibliographie, composition, similarité, autre représentation -photo, dessin, tableau-, inscription). Par ailleurs, trois sous projets pilotes de ModRef ont été sélectionnés pour réaliser la migration des données : un conservatoire numérique de l'ensemble des documents rédigés en écriture cunéiforme, un corpus numérique d'objets archéologiques à iconographie mythologique et une bibliothèque numérique sur l'histoire de France du 20ième siècle. Les données de ces différents projets sont initialement décrites dans des bases de données ou dans des fichiers XML-EAD (Encoded Archival Description). Pour réaliser la preuve conceptuelle du projet ModRef, une architecture générale a été définie; une modélisation sémantique CIDOC-CRM et un alignement des données des différents sous projets pilotes ont été proposés; une migration des données vers des triplestores a également été effectuée. Une application web a été développée et déployée. Cette application web permet de décrire le projet ModRef mais aussi de consulter et d'interroger les triplestores créés. Les triplestores posent deux principaux défis scientifiques et techniques. Le premier est la migration de données souvent décrites initialement en langage naturel vers une représentation computationnelle structurée, puis sémantique de ces dernières. L'autre défi est l'exploitation des triplestores via des Endpoint Sparql (interface de saisie et d'éxécution de requêtes Sparql) ou via des interfaces sous forme de formulaires généraux d'interrogation.

Migration de données vers des triplestores

Une migration efficace et cohérente de données fait appel à différentes compétences. Pour assurer la pérénisation de cette procédure, une architecture générale et rigoureuse du workflow des différents types de données à manipuler doit être définie. Cette architecture explicite la démarche globale de tout projet qui souhaite faire migrer ses données vers des triplestores. Cette démarche se subdivise en différentes étapes bien identifiées : préparation des données (étude et description structurelle), modélisation sémantique et alignement des données structurées avec le modèle sémantique et enfin création et exposition des triplestores qui vont alors pouvoir être consultés et intérrogés. Notons que initialement les données sont souvent non structurées ou semi-structurées (notes, rapports, livres, html) et qu'il faut dans un premier temps en extraire une représentation structurée (tableurs, base de données, fichiers XML) pour pouvoir ensuite construire leur représentation sémantique plus facilement. Ce continuum d'étapes fait intervenir des compétences diverses et nécessite parfois d'adjoindre des profils intermédiaires entre deux étapes pour assurer le passage d'un format de représentation de données à un autre : (1) données non structurées ou semi structurées vers données structurées, et (2) données structurées vers données sémantiques. Par ailleurs, l'élément clé de l'architecture de la migration de données vers des triplestores est la modélisation et l'alignement des données avec le modèle de graphe sémantique choisi. Un graphe sémantique est un ensemble de noeuds et d'arcs orientés qui obéissent à un certain nombre de contraintes et règles (raccourci, héritage, inverse, symétrie, transitivité). Ce sont ces règles et contraintes qui définissent la cohérence et la validité d'un modèle. Nous avons utilisé la version 6.2 de mai 2015 du CIDOC-CRM qui définit 94 classes et 168 propriétés ainsi que son implémentation par l'Université d'Erlangen-Nuremberg. Afin de réaliser la migration, il a fallu procéder à un alignement des données avec certains noeuds du graphe sémantique à partir des informations extraites de bases de données ou de collections de fichiers XML-EAD. Les noeuds remplis par des valeurs sont des noeuds terminaux et les noeuds intermédiaires sont remplis avec des URIs qui définissent ainsi des chemins vers les noeuds terminaux. Notons qu'une rigueur particulière doit être apportée à la construction des URIs, à la fois pour leur lisibilité mais également pour la cohérence des chemins dans le graphe afin d'éviter des conflits de chemins et garantir ainsi l'unicité d'un chemin donné par rapport à un autre. Nous avons identifié les classes utiles (menant vers au moins une valeur non vide) pour modéliser les données des projets pilotes. Ainsi, la modélisation et l'alignement effectués représentent des extraits de graphes relatifs aux quatre thèmes suivants : (1) caractéristiques générales (identifiant, type, titre, matériau, dimension, note), bibliographie, composition et similarité d'objets; (2) évènements de début d'existence (origine) et de fin d'existence; (3) activités diverses (transfert de garde, conservation, mesure); (4) inscriptions et autres représentations (photo, dessin, tableau). De façon générale, ces extraits sont assez stables pour tout projet car, dans le CIDOC-CRM, il est possible d'identifier les chemins possibles menant à une information donnée sur un objet. L'alignement n'est pas une tâche programmatique mais fait appel à des détails de structure logique propre au modèle de description de données choisi par chaque sous projet. C'est une tâche à mi-chemin entre la modélisation et l'implémentation qu'elle permet d'entrevoir un peu plus clairement. L'alignement définit ce à quoi correspond chaque noeud de notre graphe et il ne reste plus qu'à générer les fichiers CIDOC-CRM correspondants tout en respectant la syntaxe de la norme RDF. Les triplestores créés vont ensuite être exposés pour consultation (sous trois formes : *rdf, triplets et résumé attribut-valeur*) et interrogation (*formulaires généraux et Endpoint Sparql*) via notre application web. L'exploitation des triplestores via l'interrogation et l'exploration de ces derniers et les bénéfices que l'on peut en tirer est l'autre aspect majeur autour de la question de ces nouveaux entrepôts de documents RDF que sont les triplestores.

Exploitation des triplestores

L'intérêt des triplestores est qu'on a un modèle connu public et publié de représentation de l'information ce qui permet d'interroger les triplestores indifféremment avec des procédures identiques. Nous avons défini deux procédures d'exploitation de nos triplestores : des interfaces sous forme de *formulaires généraux* et des *Endpoint Sparql*. Les formulaires généraux sont un moyen simple et assez intuitif, car très proche du langage naturel, pour formuler des requêtes vers nos triplestores. Il suffit de remplir les rubriques du formulaire qui nous intéressent et de lancer la recherche. Une requête Sparql est automatiquement construite à partir des valeurs des champs renseignés du formulaire et c'est cette requête qui est utilisée pour interroger le triplestore. Au terme de l'exécution de la requête, une liste d'objets séléctionnés est renvoyée en résultat à l'usager. Par ailleurs, on peut aussi interroger nos triplestores via des Endpoint Sparql. Ce deuxième mode d'interrogation nécessite la connaissance du langage Sparql qui est aujourd'hui le langage de référence pour l'interrogation de documents RDF. Sparql est un langage assez simple mais pas toujours à la portée de tous. Ainsi, les formulaires généraux peuvent être vus comme un premier point d'entrée pour l'interrogation des triplestores tandis que les Endpoint Sparql assurent une exploitation plus large de ces triplestores via une formulation libre de requêtes de type "Select". Notons que la notion d'exploitation de triplestores fait appel aux notions d'interrogation et d'exploration de graphe. Ainsi, l'interrogation de triplestores consiste à formuler une requête Sparql pré-formatée (formulaires généraux) ou libre (Endpoint Sparql) tandis que l'exploration de triplestores est une forme d'interrogation uniquement possible via des Endpoint Sparql qui permet aussi de découvrir différents chemins dans un graphe sémantique vers des données précises. En effet, plusieurs chemins peuvent permettre d'obtenir une même information dans un graphe (usage de diverses notions : raccourci, héritage, inverse, raffinement), sachant que ces chemins ne sont pas toujours tous renseignés. On peut donc écrire des requêtes Sparql pour découvrir si différents chemins vers une donnée précise existent ou pour connaitre les noeuds terminaux. L'exploration est donc importante pour s'approprier un triplestore spécifique. L'exploration permet aussi la comparaison de différents triplestores qui décrivent des données similaires (objets d'une même période historique, objets de même type, objets identiques) dans un contexte de LOD (Linked Open Data), par exemple. Ainsi, la comparaison de chemins assure une meilleure découverte des connaissances et augmente la correction ou l'enrichissement mutuel des connaissances des différents acteurs du LOD. Notre application web fournit un LOD pour ModRef ainsi qu'une liste de modèles de requêtes Sparql pour interroger, explorer et valider nos triplestores séparément ou ensemble. A plus long terme, l'objectif est d'intégrer d'autres LOD sur internet (Beek et al., 2016) (Daga et al., 2016) pour un partage, un échange et une découverte de nouvelles connaissances à plus grande échelle. Ainsi, le LOD doit améliorer la découverte de nouvelles connaissances, du fait de l'usage de formalismes, de langages de métadonnées, de thésaurus publiés, standardisés voire normalisés.

Replication, Visualization & Tactility: Towards a Deeper Involvement of 3D Printing in Humanities Scholarship and Research

Aaron Tucker
atucker@ryerson.ca
Ryerson University, Canada

In a chapter that begins with the question "What would you make it you had a machine that could make anything?" Lipson and Kurman rhapsodically illustrate the myriad uses for 3D printing, from "3D prints [of] a precise, highly detailed replica of [a] fetus" to "the not so distant future [where] people will print 3D living tissue, nutritionally calibrated foods, and ready-made, fully assembled electronic components" (7). On-campus maker spaces often tout 3D printers with the same utopian vigor, yet there is still a great deal of opacity around how introducing 3D printed objects into a Humanities classroom or scholarship would add value to those spaces or work. In my experience collaborating and working in the Digital Media Experience Lab at Ryerson University, when asked to speak with colleagues or students about the potentials for projects that involve 3D printing, two main types of anxiety arise: first, there is the intimidation that comes with learning a new set of hardware and software; and second, there is a large amount of trepidation around what to the technology should even be used for. While the first set of fears can be somewhat mitigated by the sort of community-friendly maker space environment that 3D printers are often housed in, the second set of concerns asks questions that are at the root of not just 3D printing in the Humanities, but Digital Humanities (DH) projects as a whole:

- What are the elements of 3D printing that make it a unique contribution to the Humanities? What are the technology's strengths and how might they best be harnessed?
- What are the limits of such a technology, from both the hardware and software perspectives?

- As a physical object imbued with potential meaning, how might an tactile object speak to issues of critical theory
- What are the components of 3D printing that lend itself to a powerful learning or scholarly environment?
- What can 3D printing do that other modes of interface, data visualization cannot?

Scholars like Mark Stefik explains that "digital sensemaking" most often takes place in the ecosystems of "digital information infrastructure, such as today's web and search engines" and, as such, a great number of projects focus on a DH understanding of digital sensemaking centre around the digital components of virtual object creation. Yet, as Ian Foster argues, "Informational technology can also enhance our abilities to make sense of information, for example, by allowing exploration via visual metaphors" (19). 3D printed objects have the unique ability to make physical/concrete, at varying scales with easy replication, abstract ideas and give scholars and students modes of engagement with metaphors and issues and are not present in other mediums (print, film, music, etc). Drawing from theory and history around sculpture, this paper will ask anyone wanting to begin a 3D printed project, **what** the object they wish to create a metaphor for is, as a physical object imbued with potential meaning. If a student or scholar wants to speak to certain issues, what objects might be the best metaphors for the arguments and issues they wish to discuss? What does adding the layer of technology in 3D printing then add to that argument? What do the specific properties of replication, visualization and tactility add to the metaphor and the argument being made? 3D Printing then becomes another mode to explore visual metaphors but with the unique and obvious understanding that such an object is immediately and equally digital and analog.

Rooted in Jentery Sayer's work in discussing 3D printing alongside Lipson and Kurman's "10 principles of 3D printing" (20-24), this paper will begin to answer the above questions by outlining three core considerations, with examples, in an attempt to foster further discussion about how a relatively nascent popular technology might best be understood and undertaken in a Digital Humanities project or classroom.

First, the nature of 3D printing is built around the notion of replication: once virtual objects are constructed, they can be repeatedly printed quickly and easily. This is a massive strength when considering a large scale multitudinous project, or a classroom environment wherein students may be asked to each design or find and print an object. When printing with recyclable material, the technology lends itself exceptionally well to iteration, encouraging prototyping and low-risk failure in service of a finished product. However, the notion of replication also extends to the technology's ability to mirror "real life" (and future, fantasy) objects: projects like Morehshin Allahyari's Material Speculation are able to recreate lost objects destroyed by ISIS and reprint them, effectively regenerating a version of the physical object that both evokes the original and challenges its audience by layering the technological on top of the original craftsmanship/artistry. I will blend this with discussion of Odile Fillod's project printing models of the clitoris as an educational and feminist tool of inquiry.

Second, 3D printing allows creative and untapped modes of visualizing data. A number of data visualization tools, especially for beginners in DH, are going to be relatively simple 2D graphics, such as charts, graphs, maps etc; advanced tools will include movement, interactivity, and pleasant aesthetics. Yet, the interfaces that 3D printed objects promote are distinctive in their mix of the physical and virtual. Using examples from Lipson and Kurman's chapter "A Factory in the Classroom," as well as my own work with translating poems into small landscapes-type pieces via a height map application as part of Loss Sets, it is clear that 3D printing offers a wealth of opportunities to translate numbers, words, spaces into objects; in doing so, the object is pushed into an analog space that challenges its audience to "read" and "understand" that data in an embodied and physical manner that maintains the pleasingly interactive and evocative arguments about the information selected often found in virtual data visualization tools.

Lastly, 3D printed objects have a sensual tactility that is difficult to get from other (virtual) elements of Humanities scholarship. Once printed, the objects have concrete weight and volume that points to a set of aesthetic values again straddling their digital-analog nature; they can be picked up, turned over, and explored from a multitude of angles. Too, as wearable computing increases, 3D printed fabric projects an engaged scholarship linked immediately to the sensations and shapes of the body. Generating projects that take advantage of the physicality and materiality of such objects can be an exceptionally effective and emotive mode to considering virtual or past objects, especially as printed objects can be treated, post-printing, to change the plastic's original properties. To this end I will be looking closely at Neri Oxman and the Mediated Matter Group's Lazurus and Vespers, a "series of death masks" as well as Donna Szoke's Decoy.

Before considering potential software or materials and hardware, a DH project involving 3D printing will be most effective if it begins by considering these principles, understanding the strengths and core of the technology itself, and then blending each element together into a symbiotic environment in which the object itself is capable of housing the necessary evocative complexity and wonder that the technology itself often provokes.

Towards Feminist Data Production: A Case Study From Comics

Alexander Turton
a.turton@uea.ac.uk
University of East Anglia, United Kingdom

Introduction

This paper will take my ongoing doctoral research designing resources for analysing individual graphic novels as a case study and starting point to discuss how we can produce data in the Humanities which can be called 'feminist'. It will engage with the significant debates on this topic which are emerging in the Digital Humanities (Clement, 2016) (Drucker, 2012) (Losh et al., 2016) (Posner, 2016) (Rhody, 2016), particularly the panel discussion on creating feminist infrastructure at DH 2016 (Brown et al., 2016). Marking up images and designing ways in which to make them communicate with a comic's words are highly subjective enterprises. By explaining how I dealt with this issue in my research, this paper will outline how the subjectivity involved in creating our own data structures and ontologies, and these elements' inherent statuses as arguments about data, is a strength, an affordance, of such an approach, as well as something that embraces the situatedness and plurality of data that feminists in the sciences (Haraway, 1988) (Irigaray, 1985) have advocated for and which, more recently, have been advocated for in the Digital Humanities. Although my case study focuses on contemporary comics, this paper will explain how some of the resulting principles can be employed by data creators today in other disciplines and the GLAM sector.

Background and method

As a Digital Humanist operating outside of a specific department or centre, the question that I hear most often about my work is how I make the resources which I create objective, how I avoid my datasets merely reflecting one individual's interpretation of a text. But when I mark up an image in a certain way, or use a database structure to reflect the rhizomatic structure of a graphic novel, I do so not because it is 'appropriate' or a 'good fit', but because that is an argument I want to make about comics and their meaning mechanism, and by applying that algorithm to the dataset that is the comic, I articulate that argument, mobilising it and making it available for evaluation. I am not trying to enact as little violence as possible to a text; I am making an argument about it. This idea that datasets, data structures and algorithms are arguments that are made about texts or other objects of study is relatively well-established in Digital Humanities (Ramsay and Rockwell, 2012) but it is more often framed as a caution than an opportunity.

Working on contemporary comics, where there is no pre-existing database, and no automated or straightforward tagging of images, it would be easy to see mark-up or tagging as a hurdle, and a problematic one at that, given the fraught nature of remediating pictorial information into values that can be entered into a database. But, although I must design my own data tags and ontology, I do not have a mandate to preserve, gatekeep, or distribute otherwise inaccessible data since my objects of study are widely available. Focussing on individual texts, too, affords me time to spend designing tailored data tags and ontologies. I do not need to preserve, that is my freedom; I cannot be 'objective', that is my strength. My objects of study are relatively small; that means I do not have to be singular, I can be multiple.

Digital approaches, especially to comics (Walsh, 2012) (Dunst et al., 2016), often rely on a single categorisation of each entity or attribute. This paper will argue, rather, that our databases ought to be multiple. Rather than text-mining, a metaphor which suggests the removal of gratuitous material, I would encourage thinking of this practice as data curation, or rather, curations. Consider the analogy of a virtual museum with access to a complete catalogue of material – for is this not like our complete texts? – where anybody can hang the material in whatever way, in whatever ways, they choose. Different paths through the information can be curated, different logics created, retaining the plurality of signification that each piece holds, resisting positivism. This may well tell us as much about our hypothetical hangers as about the hung objects, but therein lies an opportunity. If curation – like datasets, data structures and algorithms – is argument, then why not bring multiple perspectives into conversation? And if we can represent data multiplicitously, we can do it investigatively. By creating multiple ontologies and data tags it is possible to embrace Brian Massumi's judgement, "[t]he question is not: is it true? But: does it work? What new thoughts does it make possible to think?" (Deleuze and Guattari, 1987: xv)

Since datasets are arguments, marking up the same data differently allows researchers to avoid asserting single values for complex, or simply ambiguous, pieces of information. It also liberates us to encode arguments we disagree with, or at least that we concede are problematic, in order to better understand or critique them. The reduction of gender to a binary, for instance, has been highlighted as an issue in quantitative approaches (Clement, 2016). This, of course, drags up familiar tensions between anti-essentialism and feminism, but if we can encode different modes of representing gender – or any other 'attribute' which is better represented on a spectrum – including the reductive binary mode, we can maintain the plurality of our data, whilst retaining the possibility to see how the text subverts such a binary categorisation; we bring the text to bear on the theory and in so doing, better understand the theoretical position of the text. Image tagging can operate in a similar way, by tagging the same pictorial signifier in multiple ways we can tag with an intention to investigate, not merely minimise violence to the text. By contrasting and combining different ontologies it is possible to shed light on our texts and to allow our texts to shed light on our ontologies, all the while fracturing any notion of computational methods as objective black boxes by foregrounding their artificiality.

Conclusion

Embracing a conceptualisation of Humanities data as complex and plural, this paper will use examples from my own research remediating graphic novels into databases to demonstrate how deploying multiple tags and multiple ontologies not only instantiates a more feminist approach to data but is actually a productive methodology for analysing texts. It champions not the analysis of datasets, but rather an analysis by datasets. As Laura Mandell said in Krakow, we need "metadata built for thinking, not sustainability." (Brown et al., 2016)

Iterative Data Modelling: from Teaching Practice to Research Method

Pim van Bree
pim@lab1100.com
LAB1100, The Netherlands

Geert Kessels
geert@lab1100.com
LAB1100, The Netherlands

Introduction

Data modelling is an essential process of almost any digital humanities project (Flanders and Jannidis, 2015). Whether texts, images, or any other form of data is mapped or analysed, a model has to be conceptualised that describes the data and forms the bedrock of the application that contains or analyses the data.

Since data modelling in the humanities is largely perceived as an epistemological process, rather than an ontological process, there is a tension between the way in which material and knowledge presents itself and the manner in which material and knowledge can be described on a generalised or abstracted level. As Flanders and Jannidis (2015: 236) have pointed out: "Some of the most fertile and urgent areas of digital humanities research involve the question of how to develop data modeling approaches that accommodate both the self-reflexivity required by humanities research and the actionability and computational clarity required by the digital domain."

In this paper we reflect on a data modelling approach that has proven to be an effective teaching practice as well as a useful research method. The iterative data modelling approach we put forward focuses on a continuous shift between three levels of data modelling: conceptual level, logical level, and interface level. We have found that this approach provides students and scholars in the humanities ("scholars") with the skills they need to translate their body of data or research question into an operational process that produces rich (inclusive; fuzzy and uncertain) and complex (advocate divergent classes) actionable datasets. It is important to note that even though it is useful when a scholar can develop their own data model for computer-aided analytical purposes, we should not underestimate the learning curve this new skillset requires.

This paper focuses on experiences we gained from data modelling practices in the humanities aimed at developing a relational database. We draw on the results of over 20 courses and workshops for scholars we have held in the past three years on developing data models and using database applications. These insights are also informed by the continuous development of the research environment nodegoat, developed by the authors of this paper, and the scholarly collaborations resulting therefrom.

Challenges

Most scholars do not perceive their material or knowledge as 'data' (Posner, 2015). Once a scholar has accepted that lists of people, statements, and ideas can also be seen as data and that we do not necessarily need to be able to count with them, it becomes clear that their material or knowledge can be modelled as well. Like the analog card catalog, a database helps to store data properly and sustainably. This allows us to filter and query the data. We can then also create networks and analyse relationships. It is important to note that vagueness, uncertainty, and incompleteness can be incorporated in a data model.

To allow scholars to operationalise the data modelling process, three levels of a data model have to be studied. The conceptual level, the logical level, and the interface level describe the data at hand, each in its own way. Here, it is necessary to reflect critically on hidden assumptions in the choice of entity types and classifications (Erickson, 2013). An iterative data modelling approach is largely research driven, although existing standards could be used as well. By asking scholars to operationalise their own data model, rather than using or implementing a pre-existing model, they get acquainted with the complexities and granularities that operationalising a data model entails.

The interface challenge - how to operate a database application? - is very important. We see the translation of the data model into an actual database as a vital step to get a good understanding of the data modelling process. We prefer to do this with a database application that has a graphic user interface to be able to iterate quickly and to easily compare data models.

Teaching Practice

The participants in our data modelling workshops ranged from undergraduates to established scholars. These workshops were either in the format of intensive one day workshops or stretched over multiple events in the course of months. During a workshop, we first addressed the aforementioned challenges to show that the challenges participants face are not new and that we can critically reflect on them. Secondly, we did collective exercises to give participants an understanding on how data models and database applications work.

When we then asked them to conceptualise a data model based on their own research question, most participants did not know where to start. The reason for this seemed to be twofold. First, they were unable to process new information regarding data modelling and the database application into an operational process. Since most of the participants were trained to conduct research with a syntagmatic dimension in mind, a linear text, it was hard to execute a research process that leads to a paradigmatic dimension, a database (Manovich, 1999). Secondly, since they were invested in the complex and unique aspects of their research project, they were unable to operationalise a coherent model while keeping relevant variables and complexities in mind (Beretta, 2016).

To overcome this, we introduced an iterative approach that took them back and forth from their research question to a partial conceptual data model, to a partial logical model, and to a partial functional database application. This process helped them to first understand how to translate one class of information to a single, non-relational, data table. Once they could process basic typed values (strings/numbers), they started to work with texts, images, dates, and locations. These steps informed participants on the transformation of a conceptual idea into a table with fields in a database application. They first focused on the basics, the finite, while leaving growing complexity, the infinite, to next iterations: creating additional data tables and constructing relationships between them. After these practical questions had been tackled, attention was shifted towards uncertain data, fuzzy data, and the question on using existing standards for a data model.

In literature on data modelling processes, a distinction is made between the conceptual/logical level and the level of the application. A data model should be portable and not dependant on one application (Flanders and Jannidis, 2015). However, this does not mean that the conceptual/logical level may not be informed by the application while teaching data modelling practices. The feedback loop between these different levels has proven to be an essential step in helping scholars understand how their own research project can be translated into a data model and a functional database application.

Research Method

The iterative data modelling approach is also of value as a research method. The aforementioned distinction between the conceptual/logical level and the interface level works well when the data for a data model is complete and unambiguous and the process in which the data model plays a role is completely mapped out. Obviously, these variables rarely hold true for research projects in the humanities.

Oftentimes the data model does not correspond with data at hand. First, a data model may ask for data that is not there for the majority of data objects. Secondly, data may be too vague to fit typed fields defined in a data model. Thirdly, a data model may lead to a research process that is too time consuming due to its level of detail. In all these cases, revisions of the data model are needed in order to continue the research process.

Instead of smoothing out irregularities in the data by simplifying the data model, the model should be adjusted to reflect the existing complexities, vagueness, and uncertainties. As Rawson and Muñoz (2016) have stated, scholars should "see the messiness of data not as a block to scalability but as a vital feature of the world which our data represents and from which it emerges." We encourage scholars to include these data driven practices into their data model and have developed various strategies and features, such as 'reversed classification', to allow them to do this in nodegoat (van Bree and Kessels, 2014; van Bree and Kessels, 2017).

With the iterative methodology applied in nodegoat, we have facilitated research projects in the range of: disambiguation of Babylonian letters, questions of provenance and intertextuality in medieval manuscripts, creation of a multi-sourced 19th century context of conference attendance on social issues, mapping structures of violence in 1965 Indonesia, and documentation of an actor-network towards an encyclopedia of romantic nationalism.

An iterative data modelling approach allows scholars to enrich their data model during the research process. While a scholar may first want to use their own model, this can later be transformed or mapped to existing standards, like CIDOC-CRM, or semantic web standards. The data itself may be enriched by adding external identifiers such as VIAF identifiers or identifiers to other linked open data resources. This last point is important when data is published as an actionable dataset online (Berners-Lee, 2006).

Conclusion

In this paper we have set out to describe an iterative data modelling approach that helps scholars become confident in modelling their data and that functions as a research method for database development in the humanities. We have argued how a continuous shift between three levels of data modelling helps to conceive actionable datasets and establishes a framework for dealing with the complexities associated with humanities research.

Defactoring ‘Pace of Change’: Exploring Code Review Methods for Textual Scholarship and Literary Studies

Joris J. Van Zundert

Huygens Institute for the History of the Netherlands Royal Netherlands Academy of Arts and Sciences

Matt Burton
mcburton@pitt.edu
University of Pittsburgh, United States of America

Introduction

We start from the assertion that coding and code—as the source code of computer programs that is readable to humans and which drives the performative nature of software (Ford 2015, Hiller 2015)—can be inherent parts of scholarship or scholarship by and of themselves. That is: we assert that code can be scholarly, that coding can be scholarship, and that there is little difference between the authorship of code or text (Van Zundert 2016). The dichotomy that has been often sought between on the one hand a ‘pure’ intellectual realm associated with scholarly writing and academic print publication, and on the other hand the ‘material labour’ associated with for instance instrument making or programing, is artificial.

We argue the validity of this assertion along Burgess and Hamming (2011) and Clement (2016). These scholars refer to earlier work in which Bruno Latour (1993) casts the defining characteristic of modernity as a process of ‘purification’ which aims to contrast the human culture of modernity to nature. Burgess and Hamming observe a congruent process in academia: “Within the academy we see these processes of purification and mediation at work, producing and maintaining the distinction between intellectual labor and material labor, both of which are essential to multimedia production” (Burgess & Hamming 2011:¶11). This process serves to distinguish between scholarly and non-scholarly activities: “The distinction between intellectual and material labor is pervasive throughout scholarly criticism and evaluation of media forms. […] In addition, any discussion of scholarly activities in multimedia format are usually elided in favor of literary texts, which can be safely analyzed using traditional tools of critical analysis.” However, this distinction is based upon a technological fallacy already pointed out—as Burgess and Hamming note—by Richard Grusin in 1984. Grusin argued that Hypertext has not changed the nature of text essentially, as writing has always already been hypertextual through the use of indices, notes, annotations, and intertextual references. To assume that the technology of Hypertext has unvealed or revolutionary activated the associative nature of text, amounts to the fallacy of ascribing the associative agency of cognition to the technology, which however is of course a ‘mere’ expression of that agency.

Analogous to Burgess and Hamming, we argue that relegating the evaluation of scholarship to the reviewing of print publications is an equal fallacious ascribing of agency to the technology of written text. Such a narrow understanding of scholarship presupposes that something is scholarship because it is in writing, that writing makes it scholarship.

It is possible to evade all such possible technological fallacies by understanding scholarship as argument. We argue therefore that scholarship in essence is argument, and that technologies enable to shape and express that argument. This is not to say that technologies are mere inert and neutral epistemological tools, obviously different technologies shape and affect argument in different ways. Different technologies can therefore enrich scholarly argument. Scholarship is thus not bound to the use of text as an epistemological technology, but essentially is in the shaping of an argument. Text and writing may still be the most celebrated semiotic technologies to express an argument, but computer code understood as ‘just another’ literacy (cf. Knuth 1984, Kittler 1993, Vee 2013) can equally be the carrier of scholarly argument.

However, the acceptance of code as another form of scholarly argument presents problems to the current scholarly process of evaluation because of a lack of well developed methods for reviewing and critiquing scholarly code. Digital humanities as a site of production of non conventional research outputs—digital editions, web based publications, new analytical method, and computational tools for instance—has spurred the debate on evaluative practices in the humanities considerably, exactly because practitioners of digital scholarship acknowledge that much of the relevant scholarship is not expressed in the form of traditional scholarly output. Yet the focus of review generally remains on “the fiction of ‘final outputs’ in digital scholarship” (Nowviskie 2011), on old form peer review (Antonijevic 2016), and on approximating equivalencies of digital content and traditional print publication (Presner 2012). Discussions around the evaluation of digital scholarship have thus “tended to focus primarily on establishing digital work as equivalent to print publications to make it count instead of considering how digital scholarship might transform knowledge practices” (Purdy & Walker 2010:178, Anderson & McPherson, 2011). As a reaction digital scholars have stressed how peer review of digital scholarship should foremost consider how digital scholarship is different from conventional scholarship. They argue that review should be focused on the process of developing, building, and knowledge creation (Nowviskie 2011), on the contrast and overlap between the representationality of conventional scholarship and the strong performative aspects of digital scholarship (Burgess & Hamming 2011), and on the medium specificity of digital scholarship (Rockwell 2011).

The debate on peer review in digital scholarship however, has been geared much to high-level evaluation, concentrating for instance on the issue how digital scholarship could be reviewed in the context of tenure track evaluations. Very little has been proposed as to concrete techniques and methods for more practical level applied peer review of program code. Existing practical guidance pertains to digital objects such as digital editions (Sahle & Vogler 2014) or to code as cultural artefact (Marino 2006), but no substantial work has been put forward on how to peer review scholarly code. We are left with the rather general statement that "traditional humanities standards need to be part of the mix, [but] the domain is too different for them to be applied without considerable adaptation" (Smithies 2012), and the often echoed contention that digital artefacts should be evaluated as such and not as to how they might have been documented in conventional articles. The latter argument probably most succinctly put by Geoffrey Rockwell (2011): "While such narratives are useful to evaluators [...] they should never be a substitute for review of the work in the form it was produced in."

Yet, the problem is growing more urgent. Increasingly, code is created and used as a mechanism of analysis in textual scholarship and literary studies—cf. for instance Enderle 2016, Jockers 2013, Piper 2015, Rybicki et al. 2014, and Underwood 2014—which leads to the need to evaluate the technical, methodological and epistemological qualities of such code, as for instance the 'Syuzhet case' showed (Swafford 2016). The algorithms, code, and software that underpins the analyses in these examples of scholarship are not standardized 'off the shelf' software productions. These code bases are nothing like a software package or product such as AntConc that can be viewed as a generic and packaged distributable tool; a tool that might be subject to a scholarly type of tool criticism explaining and opening it for reuse by other scholars. Instead these codebases are bespoke code: they are one-off highly specific and complex analytical engines, tailored to solving one highly specific research question based on one specific set of data. Reuse, scalability, and ease-of-use are, justifiably (Baldrigde 2015), not specific aims of these code objects at all. Such might be the case with generic software, but these programs have been algorithmic instruments tailor made to serve the research case at hand. As such—and following what was argued above—we must regard these code bases as an inherent part of the scholarly argument they contribute to. And as such they deserve and require specific and rigorous peer review, like any argument in humanities research. How such peer review should be conducted is, however, a large unknown.

As a contribution to the challenges of code peer review we present an experimental technique we call defactoring. Drawing on Braithwaite (2013), we have re-configured the program code that underpins a recent article by Ted Underwood and Jordan Sellers (Underwood & Sellers 2016) into a computational narrative—echoing Knuth's literate programming (1984)—to be critically analyzed and annotated. This method is intimately intertwined with the Jupyter Notebook platform, which allows for the composition of scholarly and scientific inscriptions that are simultaneously human and machine readable. The Notebook is both a document format and a platform for mixing code and prose into executable objects. We have extracted Underwood and Seller's code and defactored it into a Jupyter Notebook, available on Github. This means we have recombined code from disparate files, linearized the execution path, demodularized function calls, and annotated code blocks with our own expository comments. As an annotated Notebook we can now engage Underwood and Seller's code directly as a scholarly inscription and more deeply interrogate the role of data, algorithms, and code in the production of knowledge.

In the case of scholarship that uses computation, large parts of the intellectual importance are embodied in the code rather than living exclusively in the print publication. As our case study also shows, usually the method description in the print publication presents the intellectual contribution of the code development in a very reduced, and rather imprecise high-level fashion. The code itself is a more precise inscription of the analysis the researchers conducted. The methodological approach we present is a way to engage the code, and thus allows a peer reviewer to understand and interpret the intellectual narrative of the code. This results in a fuller grasp and understanding of the methods applied, and thus to a more comprehensive review of the intellectual effort associated with the publication.

After demonstrating the work in the notebook, we will conclude our paper with a critical reflection of the reviewing work that was undertaken with it. We identify the applicability, feasibility, benefits, and drawbacks of this specific approach. We also outline some possible future directions of research that could further contribute to exploring review methods for code scholarship.

Less intent, more impact: Transforming public DH projects toward access, care, and inclusion

Amanda Visconti
amandavisconti@gmail.com
University of Virginia, United States of America

Good intent carries no guarantee of a positive impact on the world. For digital humanities designers and makers building projects that face or involve public audiences, we have an extra scholarly and human responsibility for all the repercussions of our work. Focusing not on what we mean to create, but on how our work could both positively and negatively affect others, enables a more caring, accessible, and inclusive DH.

This paper uses my design, coding, and user testing of the participatory digital edition of James Joyce's challenging novel Ulysses, *Infinite Ulysses* (InfiniteUlysses.com), to demonstrate a public DH project designed with care for its impact on both its audience and the DH community. More importantly, I'll explore how ethical design considerations such as increasing accessibility and inclusion can be added or increased in existing projects that may not have explicitly built these values in from the start.

Infinite Ulysses is a public digital humanities project that has drawn over 25,000 unique site visitors, as well as a smaller body of 775 readers who created user accounts to interact more closely with the digital edition through annotation and other social features. *Infinite Ulysses* is also the bulk of a unique, successfully defended, no-chapters literature dissertation, and as such those interested in the future of humanities graduate education may enjoy this paper.

Building the *Infinite Ulysses* digital edition helped me separate the scholarly values of textual scholarship from the common embodiment of these values (i.e. the scholarly digital edition or SDE). Through this clarification, I imagined new types of digital edition that, while different from SDEs, hold true to the same values performed by SDEs. Through building and testing the public use of one of these new models for reifying textual scholarship values, I experimented with designing an edition that is not just publicly accessible, but also invites and assists public participation in the scholarly love for a text's materiality, history, and meaning. On the spectrum of crowdsourcing engagement, I located multiple paths for meaningful public DH activity that fall between the endpoints of full critical rhetoric and "adding a tag". To enable this public engagement, I explored ways of designing participatory digital editions to adeptly handle an influx of public readers and their annotations, and tested suggestions on what scholars can learn about digital editions and their texts from the accompanying influx of website use data.

The Femtechnet scholars' recentering of DH on ethical questions around technology design led me to connect the fields of textual scholarship and human-computer interaction, porting concepts of humane and ethical digital design to the domain of literary editions. Michael Muller's formulation of participatory design as a "third space" connecting two audiences helped me support both scholarly and public edition readers in "challenging assumptions, learning reciprocally, and creating new ideas, which emerge through negotiation and co-creation of identities, working languages, understandings, and relationships, and polyvocal (many-voiced) dialogues across and through differences". Katie Shilton's exploration of how the design of a technology shapes the social values and ethics of its users helped me plan toward a community of annotators that would care for rather than compete against one another.

My post-dissertation work on *Infinite Ulysses* pulls in thinking from libraries and information science. Librarian Chris Bourg's argues that neither technology nor knowledge infrastructures such as libraries can be neutral, and that therefore we must leverage both toward, rather than away from, social justice. Archivist Jarrett M. Drake calls us to move beyond current institutional archives to build knowledge structures that let us "unlock our futures as humans, as community members, as archivists, and as memory workers", and suggests design that encourages perceptions of community belonging as a way forward. Digital Library Federation Director Bethany Nowviskie asks, "Can we position our digital collections and digital scholarly projects more plainly not as statements about what was and is, but as resources for the building of different, better worlds?" The knowledge infrastructure of libraries and archives ports well to that of digital editions, as well as to DH more broadly. Each of these thinkers push us to create work that would take us from what DH is to what DH can be; in this presentation, their arguments act as direct prompts for exploring small ways of designing toward a better DH through the specific use case of *Infinite Ulysses*.

This paper quickly but clearly paints a cohesive picture of the *Infinite Ulysses* project, instead spending the bulk of its time critiquing the impact of the project on its users and on the DH community. I will survey the critical DH cultural scholarship that grounded my assessment of the ethical impact of my work (e.g. Roopika Risam, Moya Bailey, Amy Earhart), as well as scholarship in related areas such as libraries feminist interface design (e.g. Bess Sadler, Catherine D'Ignazio and Lauren F. Klein, Shaowen Bardzell and Eli Blevis).

In "Do Artifacts Have Ethics?", Michael Sacasas proposes a series of questions to be asked by anyone making something of what they're making—whether that's building an app, designing a class, or in this case designing and coding a digital humanities project. I use Sacasas' provocations to examine the successes, failures, and difficult decisions of *Infinite Ulysses*' design, walking the audience through concrete examples of what I did, what I should have done, or what I could do to make the project have an even better impact on the world.

- *An example of a positive impact on Infinite Ulysses' users:* I provided my annotators with the ability to export their textual annotations from my website, giving them ownership and control over the results of their labor, and not forcing them to risk losing their work if my site crashed or closed.
- *An example of a negative impact on Infinite Ulysses' user*s: I tried to populate the digital margins of Ulysses with the characters in the book, by letting new users choose among illustrations of the novel's characters for the avatar that accompanies their textual annotations. The makeup of Joyce's text means that those avatars were largely white and male, with three white female options, a cat, and no other identities. For a text that already struggles with instances of sexism, racism, and transphobia, making new readers feel "I'm not represented here, I'm not supposed to be here" was an additional negative impact.
- *An example of a positive impact of Infinite Ulysses on the DH community:* I demonstrated that a public DH project could support meaningful public participation that didn't necessitate bending public questions, interpretations, and other comments on Ulysses to fit the mold of scholarly rhetoric. By both successfully designing for public participation (my edition was cited in The New York Times) and performing innovative humanities scholarship through that design (the

project received my university's 2016 award for arts and humanities distinguished dissertation), I added to the digital humanities' ever-growing examples of how building can itself be critical research.

- *An example of a negative impact of Infinite Ulysses on the DH community:* I deepened digital editions' duplication of the problems with the print literary canon, by building a project around another canon text and author. When only 11 of 86 projects funded by the NEH Preservation & Access Office 2006-2011 had a topic other than a white male writer, I struggle with whether the positive public impacts of my work are worth deepening our problems with authorial representation.

I act as my scholarship's own harshest critic not to paralyze other DH builders from ever making anything, but to make visible specific examples of how in small ways, by adding the skill of care to the skill of critique, we makers can build a better DH and a better world.

Dead and Beautiful: The Analysis of Colors by Means of Contrasts in Neo-Zombie Movies

Niels-Oliver Walkowski
walkowski@bbaw.de
Berlin-Brandenburgische Akademie der Wissenschaften Germany

Johannes Pause
johannes.pause@tu-dresden.de
Technische Universität Dresden, Germany

The analysis of color in movies is a topic of increasing interest in the still-young research field known as digital film analysis or *cinemetrics*. The thesis of Brodbeck (2011) is one of the early examples which have been discussed broadly. Brodbeck created a donut plot for each movie in which dominant colors of scenes are represented by colored slices within the plot. Similar approaches were taken by (Baker 2015) and (Burghardt, Kao, and Wolff 2016). Both approaches identify dominant colors of all frames in a movie and represent these colors as lines in a barcode-like visualization. In the first and the third project dominant colors are created by means of a clustering-algorithm, more precisely *k-means*. This algorithm is one of the most common approaches in *color quantization* and is also delivered for such tasks in well-known computer vision libraries like OpenCV.

However, there are several issues with using k-means for color quantization in digital film analysis which are rarely discussed within the community. One of the more obvious problems is that k-means (and other non-hierarchical cluster algorithms) require pre-definition of the number of clusters to be found. Thus, an automated analysis of around 180,000 frames in a movie does not respect the fact that there are frames which are more complex in color than others. A more sophisticated procedure exists in which the k-means algorithm is used in a loop with different numbers of cluster. In this approach the best fitting number of clusters is defined and evaluated by the *silhouette coefficient* which is applied to the result of each loop. However, Figure 1 demonstrates that the best-fit in terms of clustering is definitely not the best-fit for the interpretation of colors in film analysis.

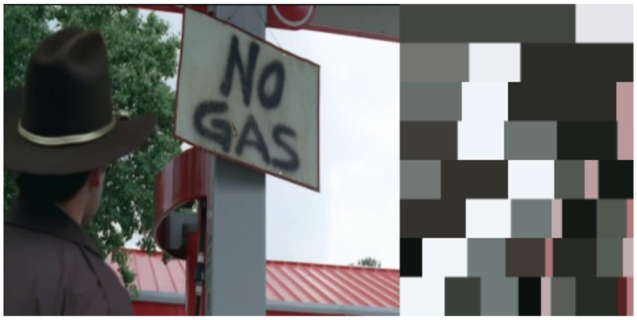

Figure 1: Cluster analysis of dominant colors in a frame image of *The Walking Dead.* According to the silhouette coefficient the number of two clusters produces the best clustering result.

Colors which seem to be important even before any interpretation has taken place disappear in the clustering process because they are 'eaten' by other clusters. Figure 2 offers a very impressive example for this phenomenon. The red girl from *Schindler's List* – the most exciting thing that happens in the movie in terms of color– is not represented within the clusters transparently. The reason is that k-means has a tendency towards equally sized clusters and that the color difference is not big enough to survive this tendency.

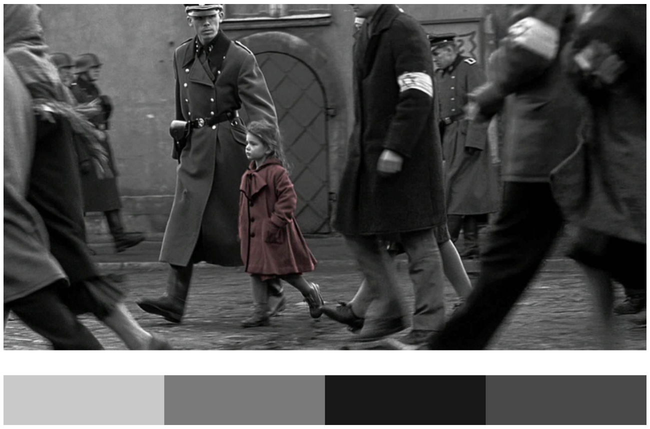

Figure 2: Cluster analysis of color in a scene from 'Schindler's List'

Another problem is that k-means produces slightly different results each time it runs. Hence, sometimes a color which would be perceived as different by humans is present in the result and sometimes it is not. The results differ most in between three and five clusters as predefined cluster values. However, this is exactly the span which is most often used for color quantization in digital film analysis. Finally, the k-means algorithm produces different results in correspondence with the color space in which a frame is represented. For instance, the HSV color space produces better results than the RGB color space.

All of these problems call for a theoretical evaluation of what dominance means for dominant colors in digital film analysis. Unfortunately, the previously mentioned projects have not presented such evaluations. Furthermore, these projects also did not systematically interpret the results they have produced. For this reason, it is not transparent which semantics can be found in the patterns.

All this being said, a different approach for the computational analysis of colors in movies seems necessary. This approach needs to introduce a starting point which is technologically less arguable and which offers concepts for the interpretation of results. The approach that will be presented builds upon the theory of *seven color-contrasts* developed by Johannes Itten (Itten 1961, 36–109). Itten claims that the effect of colors is not absolute but depends on the surrounding color environment. Colors interact with each other and there are seven contrasts in which this interaction can be analyzed. These contrasts are:

- hue
- saturation
- light-dark
- cold-warm
- complementary
- simultaneous
- extension

Each contrast has certain capabilities to structure and create effects in the narrative and aesthetic design of a movie. They can be used: to guide the attention of viewers, to create spatial ambiance, to create orientation or confusion, to support the symbolic layer or to create associations as well as emotions. Although these effects are not generalizable the approach of color-contrasts has more to provide to interpret color in movies than the analysis of single colors. This holds true especially where the dynamics of multiple contrasts are related with each other and begin to form a language of color. For instance, a movie might have a stable opposition between cold and warm colors but more progressive color dynamics (Wulff 1988) between light and dark colors. The results of such an analysis can be related to narrative aspects, characters, leitmotifs or the *Mise en Scène* in a movie or a corpus of movies.

The technological implementation of this approach depends on the type of contrast that will be analyzed. Data for the first three contrasts can be obtained by converting movie frames to the HSV or HSB color space. The conversion between the YUV color space (in which many movie files are represented) into HSV is lossless in most cases (Ford and Roberts 1998). Each channel in HSV represents one such contrast. Usage of the CIE L*a*b* color space can be considered to comply with certain issues of color awareness that are not tackled by HSV and others. Other contrasts require further processing. For instance, to obtain cold and warm color values, each value in the hue channel can be associated with a value that represents how warm or cold it is. In general, values of red and yellow are conceived as warm. However, this effect is very much influenced by cultural and psychological aspects (Küppers 2000). Therefore, the association of color values with values of warmth is a task that requires decision-making. In contrast, the presence of complementary and simultaneous colors is a mathematical relationship and can be computed within a certain color space consistently.

There are also several ways in which contrast data can be analyzed. Figures 3 and 4 visualize two of such strategies. In both cases a histogram of one contrast was computed for every second of the movie. In Figure 3 the leftmost and rightmost peaks in each histogram was calculated. These peaks constitute the min- and max-bound of the contrast span in each frame. The x-axis represents the time-axis of the movie while the y-axis shows the value of each min- and max-bound.

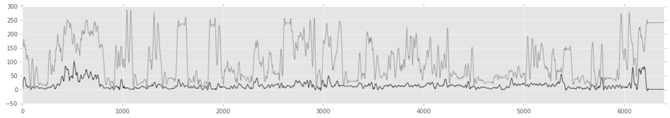

Figure 3: Slightly interpolated boundaries of light-dark contrast in '28 Days Later'

In Figure 4 the contrast of a spectrum was reduced to 16 bins and each contrast value that was produced by a critical number of pixels was plotted as a point. The size of the point represents the number of pixels in a frame for each bin.

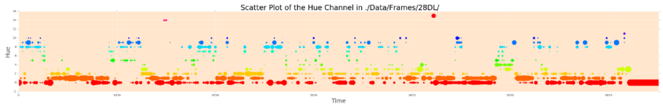

Figure 4: The appearance of hue values above a certain threshold in '28 Days Later'

The movie which underlies both visualizations is *28 Days Later*. Figure 3 represents the light-dark-contrast. It shows two sequences in which light and dark colors go up simultaneously for a certain amount of time. One sequence is between the 200th and the 800th frame the other between the 6000th and the beginning of the credits. In the first sequence the protagonist Jim awakes from coma and realizes that the world fell apart. In the second sequence the main group of persons reach the final save place. Thus, a similar pattern in one contrast frames the actual storyline. However, the color-itself-contrast represented in Figure 4 is extremely different in these scenes. The first scene has a narrow spectrum while the spectrum of the second scene is broad. The narrow spectrum provokes disorientation because it tones down differences. The color segment is literally dazzling. In contrast, the spectrum and coverage of colors at the end mediate clarity, stability and order.

This presentation will outline the problems of k-means for color quantification in digital film analysis. It will describe the theory of seven color-contrasts and give examples how such theory can be adopted computationally. Each step will be illustrated by an analysis of a corpus of three neo-zombie-movies, more precisely *28 Days Later*, '[REC]' *and World War Z*.

Livingstone Online: Access Beyond Openness

Megan Ward
megan.ward@oregonstate.edu
Oregon State University, United States of America

Adrian S. Wisnicki
awisnicki@yahoo.com
University of Nebraska - Lincoln,
United States of America

The study of nineteenth-century Africa is troubled by issues of access on two fronts. First, explorers’ unedited field notes – the closest thing we have to a “‘raw’ record” – are rarely available, and, if they are, they are often crumbling, illegible, or located in far-flung archives (Bridges 1998). Second, even when such sources are available in later published forms, they present ethical and ideological problems. Written largely by European explorers and heavily edited, the published texts often exclude the voices of the very populations to which they attempt to provide access. *Livingstone Online*, a digital project dedicated to the written and visual legacy of nineteenth-century explorer David Livingstone (1813-73), works to counter these issues through its site design, transcription processes, and use of spectral imaging technology.

In order to do so, however, we have had to reconsider our understanding of access, both technologically and ideologically. As a publicly-funded project, we adhere to a high standard of transparency. Yet, as an archive of a contentious figure of imperial exploration, we are also responsive to the recent critiques of access - both of open access as privileging imperial knowledge expansion (Christen 2012; Risam 2017) and of the digital humanities as excluding consideration of race (Gallon 2016). To navigate this conflict, we strive to provide access that is not simply based on openness.

Instead, our project offers an understanding of access that moves in two directions temporally: striving to repair the past by being ethical in our digital treatment and remediation of historical materials, while also acting in a future-oriented fashion in developing and implementing our transparency policies, data standards, and code of collaboration in order to engage a variety of audiences, including those often excluded from DH practice. In this way, our project attempts to create a digital platform for culturally sensitive materials, while our documentation procedures seek to reveal every step of our decision-making process to critical review.

Reparative

Livingstone Online, now in its twelfth year (2004 present), is a digital museum and library that draws on recent scholarship and international collaboration to restore one of the British Empire's most iconic figures to his global contexts. Our digital collection of high-resolution manuscript images and critically-edited transcriptions – 11,000 images and 700 transcriptions by 2017 – is among the largest on the internet related to any single historical British visitor to Africa. Our site publishes important research on Livingstone's legacy and explores the many ways his ideas have circulated over time. Uniquely, we also takes its visitors far behind the scenes of our work – documenting step-by-step the international collaboration among archives, scholars, scientists, librarians, computer programmers, and other specialists that has made our project possible.

Our use of spectral imaging to uncover the material history of Livingstone’s manuscripts gives us important insights into the conditions under which Livingstone and other imperial explorers wrote – from unacknowledged contributors to the many environments through which the manuscripts circulated. In foregrounding these dimensions, we are also creating a new approach to using spectral imaging in cultural heritage projects because spectral imaging has primarily been used to unearth layers of text, rather than to examine the broader circumstances of imperial record-making and the preservation of imperial records over time. This new use of spectral imaging also constitutes an ethics of access, which is framed by critical essays that explore Livingstone’s uncredited information sources. Livingstone Online here puts forward an idea of access as uncovering the hidden hands and voices of the past.

For instance, in our study of Livingstone’s 1871 Field Diary, we have collaborated with spectral imaging scientists to develop pseudocolor (false color) images to differentiate passages that Livingstone originally wrote from those he added latter and those added by other hands. Likewise, the development of animated spectral images has enabled a chronological reconstruction of events in the life of the diary. By contrast, recourse to images made by principal component analysis (PCA) has uncovered stains on pages otherwise invisible to the naked eye and has introduced us to dimensions of manuscript history otherwise not even suspected to exist.

In addition, we frame these spectral images with paratextual tools that value equally the different kinds of information that Livingstone records. For example, few or no other record remains of many of the villages or the African and Arab individuals Livingstone mentions. As a result, our integrated glossary offers unique, otherwise unavailable geographical information that circulated during Livingstone's time in Central Africa and enumerates the names of people that might otherwise be lost to history. The glossary and other critical materials also provide insight into the complex social dynamics that operated in areas where Livingstone traveled. Overall, Livingstone Online offers a version of access in which the freely available manuscript pages are only a starting point; spectral imaging technology combined with critical building helps construct a reparative ethos of access.

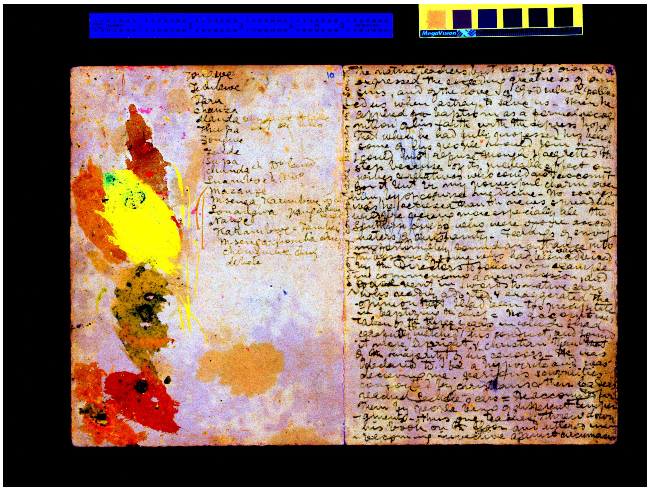

Figure 1. A processed spectral image of a two-page spread from the 10 March 1870 'Retrospect' (Livingstone 1870a:[3]). The kaleidoscopic colors foreground and differentiate the wide range of substances that have left traces on the manuscript's pages over its 145-year history. Copyright National Library of Scotland. Creative Commons Attribution-NonCommercial 3.0 Unported

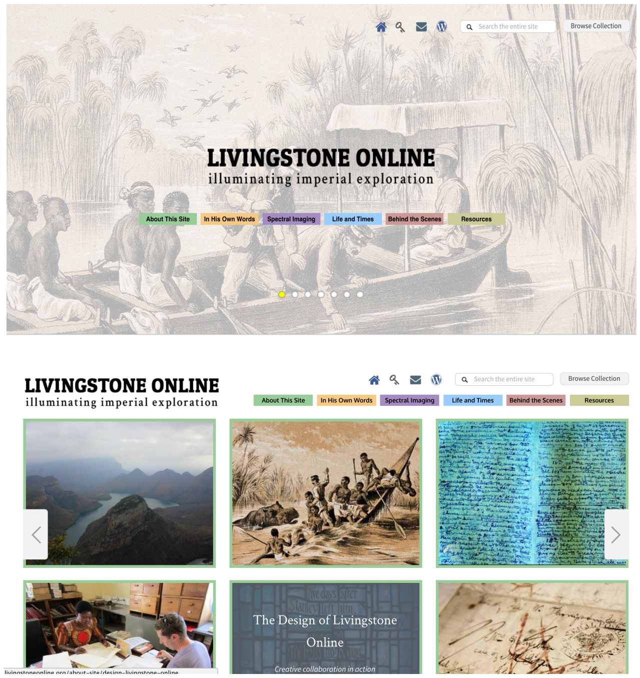
Future-Oriented

Alongside such reparative work, we also strive to design a project that looks toward the future. Livingstone Online makes our project documents available to an almost unprecedented degree in order to make our publicly-funded research fully accountable, to illuminate our work practices, and to support future digital projects. Our extensive downloadable primary materials (including 12,000 images, 3000 metadata records, and hundreds of transcriptions) are supplemented by freely available project materials, images, and working documents – the things often hidden behind the public face of digital projects. We have curated access to over 600 project documents, including planning documents, spectral image processing information, and essay notes, in order to illuminate the long-term history of our project work. Likewise, access to our grant narratives and working documents de-mystifies funding processes and international, interdisciplinary collaboration in order to support the work of other scholars, especially junior or independent scholars and those new to DH.

In addition, our site is technically accessible in a range of ways. We have built the site with sustainable, community-supported, open-source technologies such as Drupal for our front end and Fedora for our back end, which means that others can access our underlying code (which is fully available from Github) to reuse and modify it for their own projects. To promote use of our site more broadly, we've also worked to make the site inviting to scholars and general users alike, using intuitive, visually-driven site design. Through our site design, open-source code, and transparent documentation, we hope to foster user-led interpretation over passive reception of authorized knowledge.



Figures 2,3. Livingstone Online's six section pages, two of which are pictured here, each rely on a diverse range of historical illustrations and contemporary images to complicate the notion of a definitive Livingstone.

As part of this effort, our site is also fully mobile accessible, including for complex functions such as the review and study of archival manuscripts and transcriptions. This opens up Livingstone's documents and our critical materials to the parts of the world where he worked and travelled; for many people on the African continent, for instance, mobile technology is the main access point to the internet. Likewise, just under a quarter of our collaborating archives are in Africa, and we are actively working on developing additional relationships with African-based archives, in the interests of not only bringing new Livingstone materials into our site, but also to encourage collaboration with African-based scholars and general audiences.

In these ways, we hope to initiate a conversation about the biases and assumptions inherent in the ways that technological advances shape our preservation of the past. We also hope to develop a nuanced practice of access that is embedded in our site design, spectral imaging processing, and transparent documentation, as well as made explicit in our critical materials. Thinking of access beyond openness means creating more historically-minded digital collections that also look to future knowledge creation by an array of populations, not all of them academic or based in the west.

Multiplying Access: the Marianne Moore Digital Archive's Tools and Methods for Collaboration

Nikolaus Wasmoen
nlwasmoe@buffalo.edu
University at Buffalo (State University of New York)
United States of America

Introduction

The Marianne Moore Digital Archive (MMDA) has begun to publish digital editions of the 122 manuscript notebooks of Modernist poet Marianne Moore. The notebooks contain a plethora of materials, include reading notes, recorded conversations Moore participated in or overheard, drafts of poems, travel descriptions, financial records, notes on concerts, lectures, classes, and sermons Moore attended, and other miscellanea documenting an active and increasingly prominent life as part of New York's literary and cultural scene from the 1910s to the 1960s. These unique resources pose significant resistance to accessing the trove of literary and cultural data they contain: they have never been published in any form, can be visited by appointment at a library in Philadelphia for only limited hours during the week, most of the notebooks are written in a cramped, uneven hand with frequent abbreviation and shorthand, Moore repurposed calendars and other cheap or free items that include pre-printed material interspersed with her writing, many notebooks are now too fragile for normal handling, and previous attempts at conservation have led to the disordering of many pages. The unfamiliar and sometimes obscure historical and cultural references that are needed to trace the broad scope of Moore's readings and activities present an additional layer of difficulty for most of the potential audience that could take advantage of the notebooks for literary, historical, or cultural research. In response to these challenges, the MMDA has created a team of Moore scholars and scholarly digital editors at three universities and partnered with the Center for Unified Biometrics and Sensors (CUBS), an automated handwriting recognition and machine learning lab at the University at Buffalo.

This paper reflects on our efforts to increase access with respect to the notebooks in several senses: design choices with respect to the digital editorial apparatus needed to make the notebooks usable to non-specialists; the implementation of a HubZero 2.0 collaborative hub platform, designed for use in the sciences and engineering, for a humanities project; and the development of a customized, integrated editor/viewer based on existing digital manuscript editing tools that can enable non-technical editors to participate more directly in the digital workflow. The hub platform and workflow solution are primarily designed to support the specific research needs of the MMDA and its users, however the project code and our methodologies can be readily applied to other digital editing projects and digital humanities collaborations.

Abstract

Marianne Moore (1887-1972) was among the foremost modernist poets of the early twentieth- century. Her work contributed to the revolution in poetic form and conceptions of poetry occurring during the 1910s and 1920s and she remained a poet of profound reflection and innovative design throughout her lifetime. In particular, Moore was among the first to conceive the poem as constructed through both language and visual design on the page and she was the first Anglo-American poet to divorce the poetic line from syntax. While her peers such as T. S. Eliot, Ezra Pound, William Carlos Williams, Wallace Stevens, and H.D. often excoriated each others' work, all were profound admirers of Moore's thought and poetry (see, for example, Leavell 2014, and Miller, 1995 and 2005). Moore was also significant to modernism in her decades-long reviewing of work by her contemporaries, her publication of essays on aesthetic and cultural topics, and in her editing of one of the premier periodicals of modernist literature and art, *The Dial*, from 1925-1929. Moore received the Pulitzer Prize, the Bollingen Prize, the National Book Award, and the Gold Medal of the National Institute of Arts and Letters—among other awards. Additionally, she was made Chevalier de l'ordre des Lettres in France and received a Gold Medal Award for Lifetime Achievement from the Poetry Society. Her notebooks constitute a unique and extraordinary resource for understanding the composition, experience, and intellectual alertness of a brilliant thinker and poet to a very broad range of popular, mundane, intellectual, artistic, and historically significant events of her time.

The MMDA is making digital reproductions and transcriptions of Moore's notebooks readily accessible to scholarly, classroom, and non-academic readers for the first time. The transcriptions are supported by annotations contextualizing Moore's writing and life, including citations to the original source texts she invokes, and an image-text linking feature that makes it easy to move back and forth between the facsimile and the transcription. The digital editions of the notebooks are supported by a growing collection of related materials, such as indexes, a glossary, an interactive timeline of Moore's life and publications, searchable reproductions of the now hard-to-find Marianne Moore Newsletter, and faceted text and image search tools currently under development. This site will, we hope, revolutionize criticism on this significant poet; contribute to popular understanding of the modernist period's history and culture; and develop new tools for the digital editing and publication of handwritten materials.

Moore's notebooks offer extraordinary challenges for editors and digital designers because they include multiple genres, images (Moore frequently sketched objects that interested her), genetic layers of text (evidence of Moore's later editing of and additions to earlier notes, sometimes with different writing implements), and references to decades' worth of popular and academic source materials. Fully edited and annotated, Moore's notebooks suggest the deep cultural genesis of her poems: Moore's notebooks constitute not nearly finished drafts of poems and essays (that is, pre-publication texts) but, instead, a rich and varied collection of notes and compilations from which Moore drew the materials that went into her drafts and published work. Part commonplace book, part scrapbook, part sketchbook, part diary, each of Moore's notebooks offers an extraordinary window into the eclectic print and visual culture of the twentieth century and the ways in which one of America's most innovative poets responded to her world.

The MMDA addresses the special challenges and opportunities presented by these documents through a customized version of the Edition Visualization Technology (EVT), an open-source software project directed by Roberto Rosselli Del Turco (Del Turco et al, 2014-15). We have extended the tool significantly to allow for the transcription and facsimile coordinates to be edited directly in the browser, then saved automatically to underlying TEI XML files according to our project's customized TEI schema (Our viewer/editor tool was developed on the basis of the EVT version 1.0, which utilizes XSLT, CSS, and Javascript to generate its viewer. The EVT version 2 recently released utilizes a different method that removes the need for XSLT and relies on converting the TEI XML documents into JSON, which we are considering as an alternative for future development. See the EVT blog for more information about the proposed changes for version 2). This has significantly extended the utility of the EVT, and we will continue to add more advanced editing features for modern manuscript collections. This combination of editing and publishing capacity makes the editing of these manuscripts accessible to any of our registered team members directly in the browser, allowing us to address the needs of the site's editorial team and its users through the development of an integrated web platform, which we are continuing to develop along with manuscript editing tools being developed at the University at Buffalo in collaboration with the Computer Science and Engineering and the Center for Unified Biometrics and Sensors (CUBS) at the University at Buffalo. Our partners in CUBS are also developing automated handwriting recognition software that we are integrating into our platform. We aim to create a complete editorial workflow solution for transcription and annotation of manuscript collections. This is possible through the use of the HubZero 2.0 platform, based on Joomla, which to our knowledge has not previously been used for a digital humanities project.

The *MMDA* is making a vast quantity of unpublished writing by a major American poet and cultural figure freely available and easily accessible for the first time. Such access will have extraordinary impact. It is already transforming Moore studies and, as the number of publications on the site increases, it will contribute significantly to historical, cultural, and literary studies of modernism and of twentieth-century women's lives. The specialized tools and platforms for collaboration on digital manuscript editions we are developing will, we hope, serve as useful models for making manuscript collections more accessible to scholars and editors in collaboration.

Opening up the Oxford English Dictionary: what an enhanced legacy dataset can tell us about language, lexicography, and literature

David-Antoine Williams
david.williams@utwaterloo.ca
St Jerome's University in the University of Waterloo
Canada

Overview

This paper will discuss recent research carried out in the context of an OMRI-funded project: "The Life of Words: Poetry and the OED." It will discuss the processes and methods developed for enhancing and manipulating a large legacy dataset—the Second Edition of the Oxford English Dictionary—and will present analyses and applications pertaining to lexicography, lexicology, and traditional literary studies. Styled as an "opening up" of latent information in a previously closed system, and with implications in digital humanities, linguistics, lexicography, lexicology, literary criticism, and poetics, the paper will address the conference theme of "Access" in the sense of tapping into knowledge that has previously been inaccessible.

Context

The Oxford English Dictionary (OED) is widely considered to be the greatest philological and lexicographical achievement in English. As the first fascicles of the OED were being prepared, editor James Murray professed his dedication to "The perfection of the Dictionary in its data" (1880: 129, orig. emph.). The "data" of the work is its 2.43 million quotations, a significant portion of them from poetic and other literary texts, which both shape and illustrate the various sense definitions of roughly 600,000 English words and word forms. Conversely, since its publication, poets have relied on the OED to guide their deployments and arrangements of English words in poems. This reciprocal intertextuality has led to two striking facts which have yet to be fully explored: 1) that the OED's definitions of English words depend to a significant degree on poetic language, which is striking because by any standard account, poetic usage tends away from the denotative or definitional and towards the connotative and metaphorical; and 2) that much English poetry of the last hundred years contains a philological, etymological, and lexicographical dimension, informed by the OED.

Although the Second Edition of the OED (Murray et al., 1989) was among the first large reference works to be prepared for public and academic communities in digitized, marked-up form, and despite the current and ongoing revision of the dictionary (Simpson et. al., 2000-), no version has ever been marked-up with additional metadata. Information we might expect to find in a modern text dataset, such as author gender, genre of quotation, and type of publication, is not included in the OED. Attempts to incorporate such information into studies of linguistic, literary and cultural questions have until now have therefore been limited to "case-study" or "sampling" methodologies.

"The Life of Words: Poetry and the OED" addresses this by working directly with legacy versions of the electronic OED, enhancing these with appropriate metadata about the quotation evidence. With the enhanced dataset, alongside modern large text corpora, we then generate quantitative and qualitative assessments in two broad fields of inquiry: 1) What has been the influence of poetry on the English language's most comprehensive lexicographical work? and 2) What influence has the OED had on English-language poetry? To take a modern turn on Murray, our concern now is the perfection of the dictionary in its data, metadata, and comparative data.

Paper Outline

The preamble to this paper will briefly introduce the project, discussing its background, methods employed, and current stage of development, and offering some observations regarding the use of dictionaries in general, the OED in particular, and specifically the "opened-up", marked-up and directly accessible enhanced OED, as "evidence" for interpretation in a number of scholarly domains, a methodological topic which has received recent attention in dictionary studies, literary studies, and linguistics (e.g. Coleman 2013a, 2013b; Coleman and Ogilvie 2009; Hoffman 2004). The bulk of the presentation will be devoted to an exploration of the enhanced OED, demonstrating some top-level findings relevant to current scholarship in three fields. In the history of lexicography, recently there has been much discussion on the interpretation of OED quotation evidence as a complex indicator of both the prestige of certain kinds of writing over time, and the particular judgements, biases, and practices of the nineteenth-century philologists who compiled the First Edition (1884-1928) (Ogilvie 2013; Brewer 2012, 2010, 2009, 2007; Considine 2009; Mugglestone 2005, 2000; Willinsky 1994). In the first main part of the paper, I give an overall quantitative assessment of the generic make-up of OED quotations, comparing the First and Second Editions, and discuss the implications of this for literary and for cultural history. Next, at the intersection of lexicology and literary studies, I offer a re-assessment of claims surrounding the linguistic inventiveness of canonical authors such as Shakespeare and Milton (Goodland 2011, 2010; Brewer 2013, Crystal

2000; Gray 1989; Schafer 1980) based on benchmarks for the period and genre of their various works. Finally, in the realm of literary criticism, I demonstrate a number of ways that information embedded in the OED can be harnessed to detect literary tropes such as allusion and etymological wordplay, either in poems that have been directly influenced by the OED, and those for which the evidence is less conclusive.

Introduction

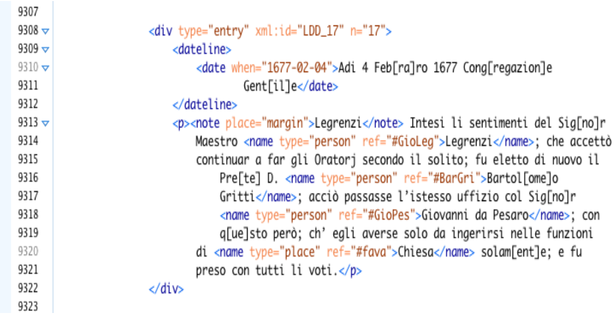
This project uses network graphs to depict musicians' careers in late seventeenth-century Venice. The current network graph, viewable on the Musicians in Venice web page, demonstrates relationships between musicians and the institutions that employed them. The graph is bimodal, with nodes representing musicians ("people" nodes) and institutions ("place" nodes). Archival texts are incorporated into the visualization, with transcriptions of records that indicate musicians' activity included in the node attributes. The entire project is text-based, with data derived from XML transcriptions of archival records in addition to assigned metadata. The current website is a proof of concept for a larger project that would demonstrate ways of displaying text as part of the network graph and using texts in creating network visualizations.

The current graph focuses on the career of the composer Giovanni Legrenzi. Legrenzi worked for several prominent Venetian institutions from the early 1670s to his death in 1690 and ultimately was appointed to the most prestigious musical posts in the city. The musicians he worked with also served multiple institutions, either simultaneously or in succession, and their relationships with other musicians, patrons, and administrators often facilitated their movement between institutions. Legrenzi's Venetian career presents an excellent case study of these musical connections in late seventeenth-century Venice, and studying these connections demonstrates how networks of musicians functioned in this time period. This study also provides a representative sample of how network visualization effectively demonstrates patterns in musicians' careers in Venice.

The texts in the network graph include transcribed administrative documents, mostly unpublished, from the Venetian institutions where Legrenzi was active between 1670 and 1690. These are primarily payment, hiring, and termination records, which document the activity of the musicians employed by or affiliated with these institutions. Several generations of musicologists have used these documents to identify where different musicians were working, when they were employed, and in what capacity (Bonta, 1964; Moore, 1981; Termini, 1981; and Selfridge-Field, 1994). In this sense, this treatment of the documents is standard to the field, but applies DH methodology and processes to create visual representations the data. This provides a new perspective on the sources. For instance, grouping the "person" nodes by centrality results in multiple sub-groups, and proximity among these nodes demonstrates shared institutions and implied communities. (Hanneman and Riddle, 2005: Chapter 10) (Mary Russell Mitford's text-based network analysis of Robert Southey's *Thalaba the Destroyer* provides an excellent example of this. In addition to demonstrating the behavior of agile, well-connected nodes, the graph displays modules of nodes as units of analysis (Wasserman and Faust, 1994: 4).

Methodology

The transcriptions of the original documents were encoded in XML with tags and attributes determined by the Text Encoding Initiative (TEI). I used the XML markup to tag the information I wanted to include in my data while retaining the complete original text. In general, I tagged the name of the musician, the name of the institution with which they were connected, and the date and location of the connection.



```
        <div type="entry" xml:id="LDD_17" n="17">
            <dateline>
                <date when="1677-02-04">Adi 4 Feb[ra]ro 1677 Cong[regazion]e
                        Gent[il]e</date>
            </dateline>
            <p><note place="margin">Legrenzi</note> Intesi li sentimenti del Sig[no]r
                Maestro <name type="person" ref="#GioLeg">Legrenzi</name>; che accettò di
                continuar a far gli Oratorj secondo il solito; fu eletto di nuovo il
                    Pre[te] D. <name type="person" ref="#BarGri">Bartol[ome]o
                    Gritti</name>; acciò passasse l'istesso uffizio col Sig[no]r
                    <name type="person" ref="#GioPes">Giovanni da Pesaro</name>; con
                    q[ue]sto però; ch' egli averse solo da ingerirsi nelle funzioni
                di <name type="place" ref="#fava">Chiesa</name> solam[ent]e; e fu
                preso con tutti li voti.</p>
        </div>
```

XML markup of primary document text

I then extracted the information for the network from the XML document using an XSLT. For this project, the stylesheet extracted the data assembled in the person index of the XML document and combined it with the entire text that documented each event. The resultant document was a CSV file of raw data that had to be separated into sets of nodes and edges to be read by the visualization platform.

The data visualization for this project was generated using Gephi, which is an open-source platform for exploratory data analysis. For this project, I generated the network graph in Gephi by importing two CSV files: one with the nodes and their attributes and ID numbers, and one with the edges and the source and target data. The online version of the network graph includes all the text associated with a "person" node in the network as a node attribute. When the user selects a person node in the online version, it displays the transcriptions for every document mentioning that person in the Information Pane. (I exported the data using the SigmaExporter plugin for Gephi. Version 0.9.0 from Gephi Thirdparties Plugins. The code is available on Github.)

Displaying all the text associated with a person node presented a challenge as the XSLT exported each connection between a musician and an institution as a new line in the CSV. For instance, if a musician was hired by a church in 1674, received a raise in 1678, and retired in 1686, there would be three lines in the CSV. When imported into Gephi, this would create three connecting edges between the person node and the place node. This created a misleading network graph, as the number of documented connections between people and places depended on the nature and availability of the records. To combine all the texts associated with the events for each person in the index, I concatenated the raw data using a PHP script and saved the results as a TSV file that could be imported into Gephi. As a result, the entire context of the decrees and decisions surrounding that musician's activity appears in the Information Pane, which also displays and links to the institutions associated with that musician. The PHP script also included HTML formatting to better distinguish the entries from one another in the visualization. Once my nodes and edges were imported into Gephi, I used a layout that grouped the nodes by degree of centrality (Algorithm in Gephi based on Blondel, Guillaume, Lambiotte, and Lefebvre, 2008. Resolution in Gephi based Lambiotte, Delvenne, and Barahona, 2009).

Network graph in Gephi

Next steps

The current graph is the foundation of a more extensive project that uses musicians and musical activity in Early Modern Venice to benefit scholars working with TEI in similar for-hire environments. In these environments, hubs of activity define the relationship between individual practitioners in the historical equivalent of a sharing economy. In the long-term, I propose an online data repository and network graph of musicians working in seventeenth-century Venice that would eventually provide a roadmap for scholars embedded in the TEI transcription model, but with an interest in an automated process for applying TEI text analysis to network analysis.

In addition to the bimodal graph that highlights relationships between musicians and their employing institutions, I also hope to create a unimodal graph documenting relationships among the musicians. Creating the unimodal network and a supporting web application will be a challenge as relationships between individuals can be complicated and dynamic. This will take considerable work in effectively diagramming entity relationships and building web applications that go beyond the "out of the box" functionality of the Gephi export plugin. The website for the Six Degrees of Francis Bacon project provides an excellent example of a unimodal graph; here the relationships are defined by circumstances (such as "father to" or "colleague of") or actions (such as "met" or "wrote to"). Linked Jazz, which uses documents as node attributes to demonstrate relationships and meaningful connections between jazz musicians in an interactive network graph, is also an excellent example. Both sites feature custom-designed entity relationships and interactive features in their web design that I want to emulate in my own network graph.

For the unimodal version, I would expand the data beyond Legrenzi's Venetian career, increasing the time frame and the number of institutions represented in the graph, and include different kinds of sources, such as periodicals, correspondence, and notarial records. Developing relationship typologies is such a crucial component to the project. This will require creating custom node metadata based on the information from the primary sources and agile development as the number and variety documents expand. The result will be a project that can better serve other scholars of Venetian music and culture.

How does Google Cultural Institute Affect the Collections of Museums? The Case of Turkey

Sümeyye Akça
sumeyyeakca@hacettepe.edu.tr
Hacettepe University, Turkey

Introduction

In recent years, progress on information and communication technology (ICT) has affected the management of cultural heritage. While ICT plays a key role in the accessibility and informed experiences of the public, it is also becoming more apparent in creating participatory platforms for people who manage and enjoy cultural heritage (Lekakis and Chrysanthi, 2011). Thus cultural memory institutions use this technology for creating digital content about their collections and making this content available from all over the world. Increasing the value of collections using sophisticated and innovative new media also affects the economic development of countries and provides more integrated awareness about cultural identity and cross-cultural communication (Brizard, Derde, Silberman, 2007).

ICT has provided a wide range of tools for cultural heritage management. Implementing these new tools also provides many advantages for both memory institutions and users. Memory institutions can manage their collections more easily with support for image processing, advanced publishing systems, and etc. Furthermore, while open access to public involvement in cultural heritage objects improves the public awareness and sense of belonging to the society, it also develops the content of the objects with crowdsourcing from all over the world. In order to benefit from these advantages of new media tools, cultural memory institutions have opened their collections to the global public regardless of geographic location. Thus, memory institutions also benefit from increasing their promotion and advertising among other countries and institutions (Myat, 2012).

One of these new media platforms is Google Cultural Institute, which has been applied to the cultural heritage area in recent years, especially in museums. The purpose of this institution is to provide broad public awareness, use and augmented access online for cultural heritage objects. It offers a range of tools that make it easy for memory institutes to put the collections online. With the online exhibitions, memory institutions can create stories about their collections. People can reach these collections all around the world using a wide range of platforms, and can share the images they like with friends using their social media accounts (Google Cultural Institute, 2016). In his 2016 TED talk, the head of Google Cultural Institute, Amit Sood says "The world is filled with incredible objects and rich cultural heritage. And when we get access to them, we are blown away, we fall in love. But most of the time, the world's population is living without real access to arts and culture." This new platform allows users to experience the world's cultural heritage objects, and to add comments about them as well.

Method

There are ten museums in Turkey putting their collections on Google Cultural Institute. All of these ten museums are private. They are as follows:

1. Salt
2. Rezan Has Museum
3. Elgiz Museum
4. Sakıp Sabancı Museum
5. Borusan Contemporary
6. Murat Istanbul Festival
7. Masumiyet Museum
8. Istanbul Museum of Modern Art
9. Istanbul Research Institute
10. Pera Museum

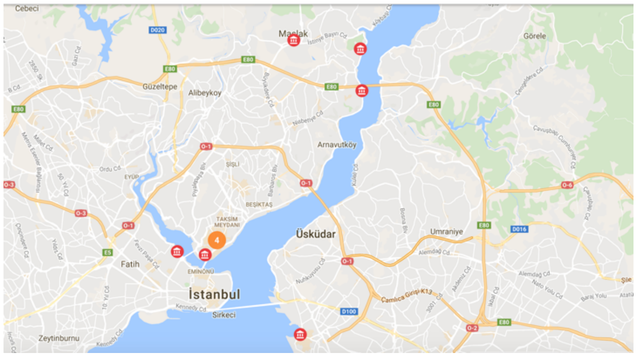

Figure 1. The partners of Google Cultural Institute from Turkey (accessed on Google Cultural Institute, 2016).

In this study, the data about visibility and access of these ten museums is analyzed looking at the previous and next data of the collections that are added to this online platform. For detailed analysis of this issue, interviews were conducted with curators and managers of these ten museums regarding their observations of this new platform. The web activities of the museums -before and after- are also visualized. In addition, the data about the social media usage of these museums and its effect on increasing visibility and access of the collections are discussed. To understand the data in this study, these research questions are answered.

1. How does this online platform affect the visibility of these collections?
2. Does it affect the diversity of visitors being national or international?

3. What are the advantages and disadvantages of this new platform?

Digital *Hansard*: Politics and the Uncivil

Marc Alexander
marc.alexander@glasgow.ac.uk
University of Glasgow

Andrew Struan
andrew.struan@glasgow.ac.uk
University of Glasgow

Summary

This short paper uses the recently-completed Hansard Corpus to show the patterning of attitudes expressed by the British Parliament about things considered to be ‘uncivilized’ across the last two centuries. It starts from the lexical resource of the Historical Thesaurus of English to gain an overview of the lexicalisation of the concept ‘uncivilized’ and uses this digital data demonstrates a substantial shift (from foreign to domestic) in who Parliament considers to be uncivil.

Introduction

The ways in which the British have discussed ‘uncivilized’ peoples which travellers have encountered throughout the history of English gives a key insight into how people in the past have identified and classified the world around them. This paper uses data from the *Hansard Corpus 1803-2003* (Alexander and Davies, 2015-) alongside the *Historical Thesaurus of English* (Kay et al, 2015–) to analyse the evolution of how the English-speaking people have thought of those who they think uncivil in five different sense-families — as animals, as ill-formed people, as strange-speaking outsiders, as savages, and finally as innocents awaiting enlightenment. Only these large digital data sources can show us the patterning of who and what the British Parliament have considered to be barbarous across time.

Data

This analysis became possible following the completion of the *Historical Thesaurus of English* (HT) in 2009 and the semantically-tagged *Hansard Corpus 1803-2005* in 2015, both of which are currently directed by Alexander and were created by teams of scholars at the University of Glasgow.

The HT is a database of all the recorded words in the history of English arranged according to their meaning; one of the world’s oldest digital humanities projects, and in progress for over 50 years, the HT database (stored on media from punch cards to tape to diskettes to networked storage to the Web) allows us an unparalleled resource for analysing the history of English. The *Hansard Corpus 1803-2005*, completed in 2015, is a digital corpus of speeches in the British Parliament between those dates, consisting of 1.6bn words across 7.6m speeches. Its contents were semantically tagged in the 2014-15 SAMUELS project (The SAMUELS Consortium, 2015) with disambiguated meaning codes from the HT, making it possible to search for semantic categories rather than words, as we do below.

The Uncivil

The category of *Civilization* in the HT gives us an indication of a non-typical pattern in the number of words available to describe a given concept (in English, categories normally grow throughout time) in the words referring to *uncivilized* and a *lack of civilization*, as Figure 1 shows.

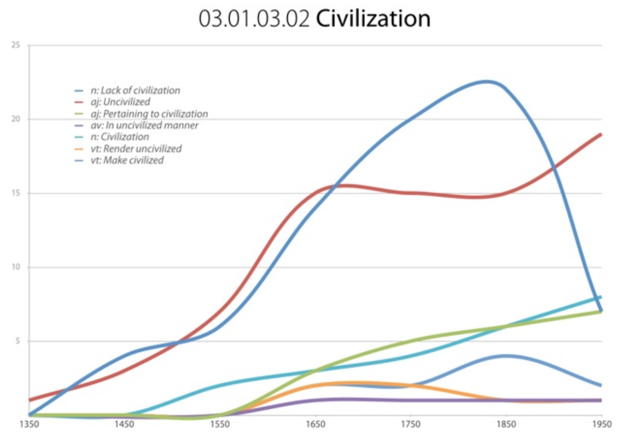

Figure 1: The size of each subcategory of *Civilization* in the HT

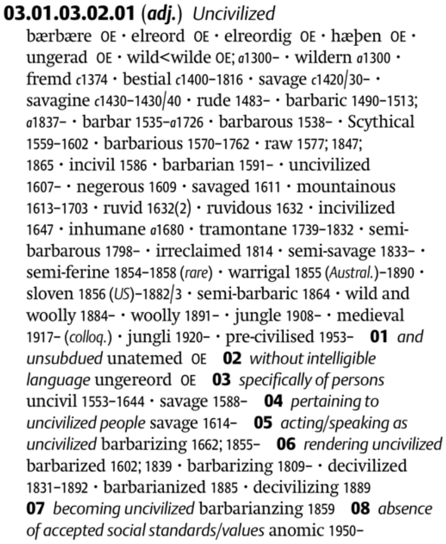
While the size of the *uncivilized* adjective category rises in the latter 20th century, there is a substantial fall at the same time in the size of the *lack of civilization* noun category, which we argue is connected to the shift in who has been considered to be uncivil (see below). In addition, of the 42 words in the *uncivilized* category in the HT (see Figure 2), the vast majority follow a particular path of lexicalization which we describe below, with new terms reflecting the shifting conceptualization of the uncivil throughout the times at which they were coined.



03.01.03.02.01 (***adj.***) *Uncivilized*
bærbære OE · elreord OE · elreordig OE · hæþen OE · ungerad OE · wild<wilde OE; *a*1300– · wildern *a*1300 · fremd *c*1374 · bestial *c*1400–1816 · savage *c*1420/30– · savagine *c*1430–1430/40 · rude 1483– · barbaric 1490–1513; *a*1837– · barbar 1535–*a*1726 · barbarous 1538– · Scythical 1559–1602 · barbarious 1570–1762 · raw 1577; 1847; 1865 · incivil 1586 · barbarian 1591– · uncivilized 1607– · negerous 1609 · savaged 1611 · mountainous 1613–1703 · ruvid 1632(2) · ruvidous 1632 · incivilized 1647 · inhumane *a*1680 · tramontane 1739–1832 · semi-barbarous 1798– · irreclaimed 1814 · semi-savage 1833– · semi-ferine 1854–1858 (*rare*) · warrigal 1855 (*Austral.*)–1890 · sloven 1856 (*US*)–1882/3 · semi-barbaric 1864 · wild and woolly 1884– · woolly 1891– · jungle 1908– · medieval 1917– (*colloq.*) · jungli 1920– · pre-civilised 1953– **01** *and unsubdued* unatemed OE **02** *without intelligible language* ungereord OE **03** *specifically of persons* uncivil 1553–1644 · savage 1588– **04** *pertaining to uncivilized people* savage 1614– **05** *acting/speaking as uncivilized* barbarizing 1662; 1855– **06** *rendering uncivilized* barbarized 1602; 1839 · barbarizing 1809– · decivilized 1831–1892 · barbarianized 1885 · decivilizing 1889 **07** *becoming uncivilized* barbarianzing 1859 **08** *absence of accepted social standards/values* anomic 1950–

Figure 2: 'Uncivilized' in the HT, taken from p.1235 of the print edition.

Thus far this sort of analysis has been slow-paced and difficult to undertake. However, with the tagging in the *Hansard Corpus 1803-2005* we can investigate this sort of semantic and conceptual change in a much more rapid fashion by honing in on uses of these meanings in context across time.

Parliament

There are five families of meaning into which the words above can be categorised, as outlined above. In a past article (Alexander and Struan, 2013), we assembled some evidence for this from the history of English in a non-systematic fashion. For this short paper, we instead account for all the evidence from the *Hansard Corpus* — over 2,000 uses of the semantic category — in order to trace across recorded Parliamentary history the shifts in the cultural, political and social attitudes towards the 'uncivilized'. This shows a substantial change in the picture which differs from the simpler five-family view of the sense evolution of *uncivil* we described in that earlier article.

Our first change to discuss is the shift, shown below, from the uncivil primarily being foreigners in the 1800s to being domestic persons in the 1900s onwards.

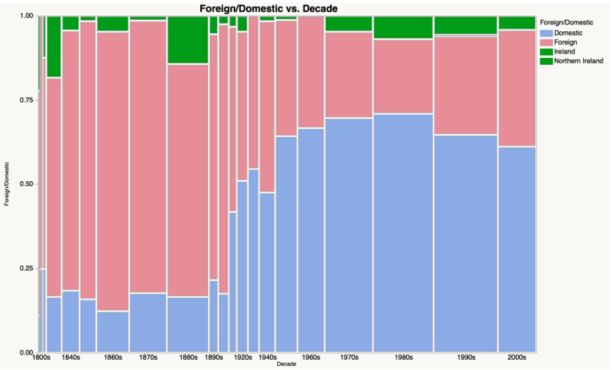


Figure 3: The proportion of uses of *uncivil* words to refer to foreign or domestic persons (thickness of bars reflects the changing amounts of text in *Hansard* in those decades); note that the status of Ireland and Northern Ireland is contested with regards to the foreign/domestic status, and so has been represented separately here

This is reflected in the changing discourse surrounding *barbaric* and *uncivil* things, where a majority of 20th century uses refer to barbaric practices and actions rather than persons:

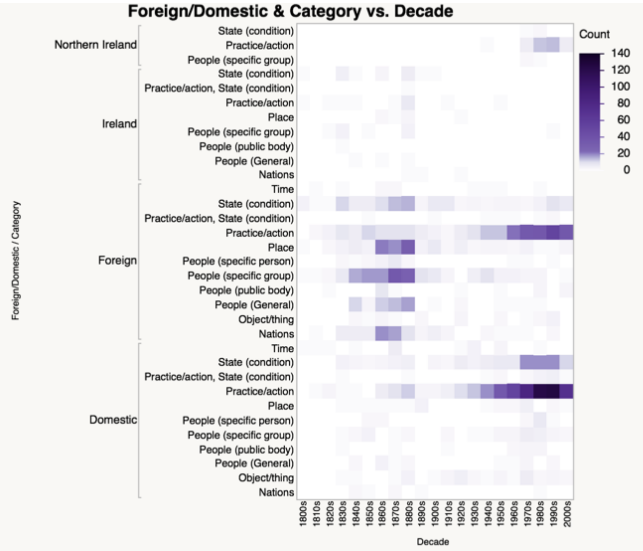

Figure 4: A heatmap of the entities (people, states, practices) considered uncivil by Parliament in the data, separated by whether the entities are foreign or domestic

Through four other graphs, we further report on the distribution of uncivil references across the globe and between the two Houses of Parliament. We also show the changes in the five evolutionary sense-families we outline above, which is key to the foreign/domestic shift we describe.

Some quotes from the corpus can briefly illustrate these changes, which here are aimed at a general body of persons, or a country:

> Mr Charles Adderley, House of Commons 21 February 1865: *'...to discharge what Lord Grey described as the singular office of dispensing rude laws among uncivilized tribes.'*
>
> Earl of Carnarvon, House of Lords 12 May 1874, on India: *'But a central government is not enough. In barbarous times and in uncivilized countries, roads are the first condition of improvement; and here it will be our first duty to open and secure the maintenance of roads and trade-paths.'*
>
> Mr Richard Cherry (Attorney-General for Ireland), House of Commons 20 March 1908: *'I never said that the people of Ireland were West African savages.'*
>
> Lord Hylton, House of Lords 18 April 1995: *'We can now see that in dealing with Russia we are dealing with a semi-barbarous state and a society that only knew a measure of democracy for a few years before the First World War.'*
>
> Mr Andrew Robathan, House of Commons 1 November 2001, on the pending invasion of Iraq: *'We should not allow a barbaric, mediaeval [sic] regime to succeed or last. We certainly do not want to go back to civil war.'*

As a result, we can show empirically the shift over two centuries in the ways which Members of Parliament described uncivil or barbaric entities, from foreign people or places to domestic practices. We conclude by arguing that this is the result of increased oppositionality being shown in the digital Parliamentary record, and so in this short paper we combine 'big picture' graphs of large-scale data analysis with more focused examples from the corpus record.

Reconstructing Readerly Attention: Citational Practices and the Canon, 1789–2016

In its ability to extract feature sets, relate texts within an abstract space, and semantically parse groups of texts, computational textual analysis has functioned primarily as a formalist intervention into literary study. When practitioners venture outside of the formal features of the texts themselves, it is author or date that serves as the point of contact between the text and its wider context. And yet, texts offer a rich history of reception: as different interpretive communities (Fish 1980) receive and reinterpret novels, poems or plays, they recontextualize the literary object to suit the particular socio-cultural goals of their period or nationality. Lacking detailed accounts of reading practices at large scales, even traditional practitioners of literary history have been unable to reconstruct the history of reception of even the most historically canonical texts. In this project, we leverage the ability of Digital Humanities to recover, at least provisionally, a large-scale history of textual reception by exploring the patterns of citation that reveal the attention paid to specific texts across their history as readerly objects. How are certain canonical texts cited over time and what can the attention paid to different segments of texts with a rich reception history tell us about the reading or social practices of different historical periods? How do different groups of readers (particularly authors and critics) quote text differently as they make use of passages in their own writing? And how do specialists and non-specialists cite the same text differently? By exploring the locus of attention within a canonical text, both across groups of readers and across history, we provisionally reconstruct a historically and socially contingent map of a text's reception history.

As Piper and Algee-Hewitt have argued in "The Werther Effect" (Piper and Algee-Hewitt 2014), practices of citation, the embedding of the language of a text within other works, can reveal patterns of reception even within a single author's corpus. In this project, we expand this approach multi-dimensionally, identifying passages of canonical works quoted in other novels, in critical articles by specialists and non-field specialists, and in a larger undifferentiated corpus of text. The scale of our analysis enables us to identify what parts of a text have received the most writerly attention overall and how that attention has been shaped over time. By moving from semantics to passages, we switch our attention from the intangible metrics of semantic similarity, to specific, quotation-level instances of citation that demonstrate specific attention to identifiable parts of our target texts. Drawing on work in sequence alignment by David Smith et al (2013) and Richard So et al. (forthcoming), we will therefore be able to explore patterns of attention that have been paid to a text by identifiable groups of readers. We argue that these patterns of citationality serve as a proxy for the reception of a text: while necessarily limited to readers who themselves were authors (or critics), they nevertheless represent an important category of reception available to analysis.

To extract the quotations, we used Python's "difflib" module, wrapped up as a parallelized MPI program that runs on an HPC cluster. To compare any two individual texts - for example, when checking for passages from Hamlet inside of a novel from the Gale American Fiction corpus - the texts are first split into tokens and passed through a filter that removes a set of 200 stopwords. This speeds up the alignment algorithm (the high-frequency words that get pulled out make up a significant portion of the total words in any given text, producing shorter sequences) and also has the advantage of making the alignment process less sensitive to small changes in function words, which seem to get shuffled around or changed fairly frequently when a text is quoted. For example, a change from:

> And crook the pregnant hinges of the knee
> **Where** thrift may follow fawning
>
> to
>
> And crook the pregnant hinges of the knee
> **That** thrift may follow fawning

still gets picked up as a quotation, since the semantically significant words - crook, pregnant, hinges, knee, thrift, fawning - stay the same.

These filtered sequences of tokens then get passed through the alignment algorithm, which produces a set of matches, recoded in terms of their starting positions in each text and the length of the matching subsequence. To ensure that the matches represent actual quotations, we discarded matches shorter than 5 tokens (not counting stopwords), since alignments shorter than this include a fair number of false positives, generic word sequences that likely don't represent any kind of meaningful quotation or intertextuality - for example, many are numbers, things like "five hundred thousand." This gives us high "precision" - almost all of the alignments that are included in the final analysis represent legitimate quotations to the play - but it also drops down the "recall" somewhat, since some of the shorter alignments are, in fact, real quotes - things like "weighing delight and dole." We are currently evaluating a couple of strategies for identifying these alignments that are short but semantically "focused" enough that we can say with confidence that they should be included in the set of valid matches.

We use this method of sequence alignment to trace the quotations of five canonical texts with a rich citation history across four corpora. Our selected texts include Shakespeare's *Hamlet*, Milton's *Paradise Lost*, Dickens' *A Christmas Carol*, Caroll's *Alice in Wonderland* and Wordsworth's *Prelude*. Not only are all of these texts heavily quoted by critics, but, we argue, they have entered the literary and cultural consciousness of both Britain and America such that the passages that are cited by authors and critics reveal interpretive and readerly practices both across time and between different groups. For each text, we extract all of the citations from it that are five words (excluding stopwords) or longer, that occur in each of our four corpora: the full-text Hathi trust corpus, representing a massive sample of writing in the nineteenth and early twentieth centuries; a literature-specific corpus of 28,000 novels from England and America dating from 1789-2016; and two corpora of articles on literary studies, one a corpus of 10 journals of literary criticism and history (e.g. *PMLA*, *NLH*, *Critical Inquiry*) and one a corpus of 10 field-specific journals focused specifically on the authors represented in our group of canonical texts (e.g. *Shakespeare Quarterly*, *Milton Studies*, *Wordsworth Circle*).

Between these four corpora, we are able to differentiate the kind of attention paid to our primary canonical texts by four different groups of readers. Do novelists pay attention to different parts of a text than authors in general in the nineteenth and twentieth centuries? Do general literary critics quote different parts of *Hamlet* than Shakespeare specialists? And for each of these corpora, how does the citation map of each of our texts change over time?

For example, a citation map of *Hamlet* in our novel corpus revealed 1,693 quotations of five or more non-stopword tokens, which collectively cover about 25% of all words in the play. When we plot the frequency of citations across the narrative of the drama (broken into 500 bins), our method reveals the passages most quoted by novelists of the nineteenth and twentieth centuries (Figure 1). From this citation map, we can see that Hamlet's soliloquy ("to be or not to be") is among the top three passages cited by novelists; however, the quotation that clearly dominates the use of *Hamlet* by this group of readers comes from Act 5, Scene 2 “There’s a divinity that shapes our ends, / Rough-hew them how we will.—“

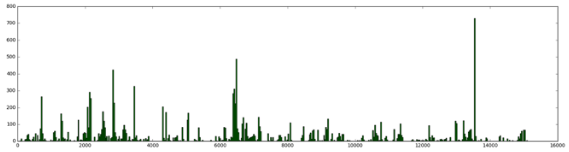

Figure 1 Numbers of citations of Hamlet in nineteenth and twentieth-century novels. Each passage is 1/500 of the text.

Although not among the most identifiable passages today, this quotation clearly had a resonance for the readers of the nineteenth and early twentieth centuries.

By comparing this map of citations across the narrative of Shakespeare’s plays to ones that are both drawn from our comparative corpora and periodized across the two centuries they represent, we are able to show how different passages gain and lose meaning across time and between kinds of reading. As we expand this to all five of our canonical texts read into all four of our corpora, we can shed light on how historically and disciplinarily specific practices of reading shaped the horizons of interpretation for specific works, and begin to reconstruct these reader-based practices in ways that are open and tractable to the Digital Humanities.

Natural Language Processing for the Long Tail

David Banman
dbamman@berkeley.edu
UC Berkeley, United States of America

Natural language processing (NLP) is a research area that stands at the intersection of linguistics and computer science; its focus is the development of automatic methods that can reason about the internal structure of text. This includes **part-of-speech tagging** (which, for a sentence like *John ate the apple*, infers that *John* is a noun, and *ate* a verb), **syntactic parsing** (which infers that *John* is the syntactic subject of *ate*, and *the apple* its direct object), and **named entity recognition** (which infers that *John* is a PERSON, and that *apple* is not, for example, an ORGANIZATION of the same name). Beyond these core tasks, NLP also encompasses sentiment analysis, named entity linking, information extraction, and machine translation (among many other applications).

Over the past few years, NLP has become an increasingly important element in computational research in the humanities. Automatic part-of-speech taggers have been used to filter input in topic models (Jockers, 2013) and explore poetic enjambment (Houston, 2014). Syntactic parsers have been used to help select relevant context for concordances (Benner, 2014). Named entity recognizers have been used to map the attention given to various cities in American fiction (Wilkens, 2013) and to map toponyms in Joyce’s *Ulysses* (Derven et al., 2014) and Pelagios texts (Simon et al., 2014). The sequence tagging models behind many part-of-speech taggers have also been used for identifying genres in books (Underwood et al., 2013).

There is a substantial gap, however, between the quality of the NLP used by researchers in the humanities and the state of the art. Research in natural language processing has overwhelmingly focused much of its attention on English, and specifically on the domain of news (simply as a function of the availability of training data). The Penn Treebank (Marcus et al., 1993)—containing morphosyntactic annotations of the *Wall Street Journal*—has driven automatic parsing performance in English above 92% (Andor et al., 2016); part-of-speech tagging on this same data now yields accuracies over 97% (Søgaard, 2011). While a handful of other high-resource languages (German, French, Spanish, Japanese) have attained comparable performance on similar data (Hajič et al., 2009), many languages simply have too few resources (or none whatsoever) to train robust automatic tools. Even within English, out-of-domain performance of many NLP tasks—in which, for example, a syntactic parser trained on the *Wall Street Journal* is used to automatically label the syntax for *Paradise Lost*—is bleak. Figure 1 illustrates one sentence from *Paradise Lost* automatically tagged and parsed using a tool trained on the *Wall Street Journal*. Since this model is trained on newswire, it expects newswire as its input; errors in the part-of-speech assignment snowball to bigger errors in syntax.

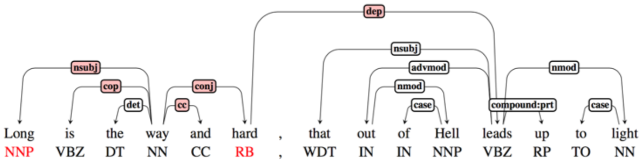

Figure 1: Parsers and part-of-speech taggers trained on the WSJ expect newswire syntax. Automatically parsed syntactic

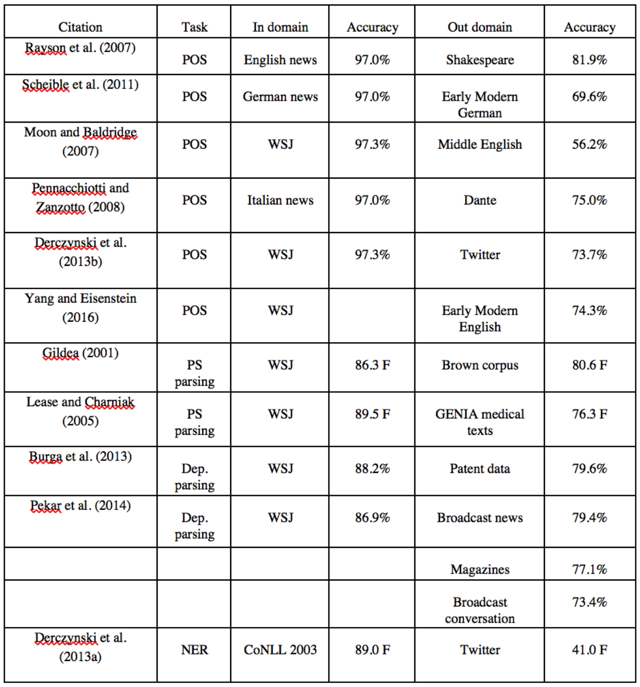
dependency graph with part-of-speech tags for Long is the way and hard, that out of Hell leads up to light. Errors in part-of-speech tags and dependency arcs are shown in red. Part-of-speech errors snowball into major syntactic errors.

Table 1 provides a summary of recent research that has investigated the disparity between training data and test data for several NLP tasks (including part-of-speech tagging, syntactic parsing and named entity recognition). While many of these tools are trained on the same fixed corpora (comprised primarily of newswire), they suffer a dramatic drop in performance when used to analyze texts that come from a substantially different domain. Without any form of adaptation (such as normalizing spelling across time spans), the performance of an out-of-the-box part-of-speech tagger can, at worse, be half that of its performance on contemporary newswire. On average, differences in style amount to a drop in performance of approximately 10-20 absolute percentage points across tasks. These are substantial losses.



Citation	Task	In domain	Accuracy	Out domain	Accuracy

Figure 2: Out-of-domain performance for several NLP tasks, including POS tagging, phrase structure (PS) parsing, dependency parsing and named entity recognition. Accuracies are reported in percentages; phrase structure parsing and NER are reported in F1 measure.

While many techniques are currently under development in the NLP community for domain adaptation (Blitzer et al., 2006; Chelba and Acero, 2006; Daumé III, 2009; Glorot et al., 2011; Yang and Eisenstein, 2014), including leveraging fortuitous data (Plank, 2016), they often require specialized expertise that can be a bottleneck for researchers in the humanities. The simplest and most empowering solution is often to create *in-domain* data and train NLP methods on it directly; in-domain data can substantially increase performance, almost to levels approaching state-of-the-art on newswire. When adding training data of Early Modern German and adding spelling normalization, Scheible et al. (2011) increase POS tagging accuracy on Early Modern German texts from 69.6% to 91.0%; when Moon and Baldridge (2007) train a POS tagger on Middle English texts, this pushes their accuracy from 56.2% to 93.7%; when Derczynski et al. (2013b) train a POS tagger directly on Twitter data, this increases accuracy from 73.7% to 88.4%. In-domain data is astoundingly helpful for many NLP tasks, from part-of-speech tagging and syntactic parsing to temporal tagging (Strötgen and Gertz, 2012).

The difficulty, of course, is that training data is expensive to create at scale since it relies on human judgments; and the cost of this data scales with the complexity of the task, so that morphosyntactic or semantic annotations (which require a holistic understanding of an entire sentence) are often prohibitive. Few projects achieve this scale for domains in the humanities, but when they do, they have real impact – these include WordHoard, which contains part-of-speech annotations for Shakespeare, Chaucer and Spenser (Mueller, 2015); the Penn and York parsed corpora of historical English (Taylor and Kroch, 2000; Kroch et al., 2004; Taylor et al., 2006); the Perseus Greek and Latin treebanks (Bamman and Crane, 2011), which contain morphosyntactic annotations for classical Greek and Latin works; the Index Thomisticus (Passarotti, 2007), which contains morphosyntactic annotations for the works of Thomas Aquinas; the PROIEL treebank (Haug and Jøhndal, 2008), which contains similar annotations for several translations of the Bible (Greek, Latin, Gothic, Armenian and Church Slavonic); the Tycho Brahe Parsed Corpus of Historical Portuguese (Galves and Faria, 2010); the Icelandic Parsed Historical Corpus (Rögnvaldsson et al., 2012), and Twitter, annotated for part-of-speech (Gimpel et al., 2011) and dependency syntax (Kong et al., 2014).

The availability of these annotated corpora means that we have the ability to train NLP tools for some dialects, domains and genres in Ancient Greek, Latin, Early Modern English, historical Portuguese, and a few other languages; this doesn't help the scholar working on John Milton, Virginia Woolf, Miguel Cervantes, or the countless other authors and genres in the long tail of underserved domains that researchers are increasingly finding high-quality NLP useful to help analyze. In this talk, I'll argue for an alternative: an open repository of linguistic annotations that scholars can use to train statistical models for processing natural language in a variety of domains, leveraging information from complementary sources (such as the works of Shakespeare) to perform well on a target domain of interest (such as the works of Christopher Marlowe). What this repository critically relies on is the expertise of the individuals who simultaneously are the consumers of NLP for their long-tail domain and are in the uniquely best position to create linguistic data to support their own work—and in doing so, can help develop an ecosystem that can support the work of others.

Les capsules vidéo de MemoRekall: la conjugaison des approches intra et inter-documentaire au service de la médiation numérique des arts de la scène

Clarisse Bardiot
clarisse_bardiot@mac.com
University of Valenciennes, Belgium

En 2004, la Tate Modern se dote d'un nouveau département intitulé *time-based media art*, lequel regroupe des œuvres se caractérisant par leur durée. Dans ce glissement de l'espace au temps, de nouveaux « objets » intègrent les collections muséales, parmi eux les performances. Pourtant, objet immatériel, éphémère, non reproductible, la performance est considérée comme impossible à collecter/collectionner. (Bishop, 2014). Seules restent les traces (photographies, captations vidéo, diagrammes, objets...), les reliques, acquises par les musées et parfois élevées au rang d'œuvres d'art. Soit la documentation mais non l'œuvre elle-même dont l'ontologie résiderait dans le *hic et nunc* de la (re)présentation et la coprésence des acteurs et des spectateurs (Phelan, 1993). Comment préserver une œuvre par nature éphémère, réputée attachée au corps de l'artiste, pour l'intégrer dans une collection permanente et être en mesure de la re-présenter au public ? Quels protocoles mettre en œuvre, quelles conditions réunir pour faire en sorte de répéter à l'infini « ce qui ne reste pas » (Van Imschoot, 2005) ? Ces questions sortent du cadre du musée. Elles concernent l'ensemble des arts de la scène, tant la possibilité du répertoire, de la reprise ou de la reconstitution.

Dans ce contexte, la documentation joue un rôle crucial. Sans elle, impossible de re-présenter une œuvre, de la « remonter » (Laurenson & van Saaze, 2014 ; Bénichou, 2015). Les technologies numériques permettent une réappropriation des contenus sémiotiques des documents, et en particulier de la captation vidéo qui jouit d'un statut à la fois privilégié et controversé. La captation vidéo a été avant la capture de mouvement la réponse à l'archivage de ce document qu'est le corps de l'interprète. Provoquant maints débats depuis les années 60, souvent considérée comme une « trahison » de l'œuvre originale (Melzer, 1995a, 1995b), elle s'est aujourd'hui banalisée. La captation vidéo est devenue un document parmi d'autres, au côté des partitions, des carnets de notes, des photographies, des croquis de scénographies, des documents de production, etc. Pour pallier les insuffisances ou les biais de la captation vidéo, deux types de stratégies sont développées : intra-documentaire (annoter la captation) et inter-documentaire (connecter la captation à un corpus documentaire plus vaste).

L'approche intra-documentaire : annoter la captation vidéo

La captation vidéo est rarement autosuffisante et appelle le commentaire, l'analyse, le décryptage. Comme le montre le récent numéro spécial de *Performance Research* intitulé *On An/Notations*, le phénomène est loin d'être marginal et concerne non seulement la pratique des chercheurs mais aussi celle des éditeurs, des artistes et du public (deLahunta, Vincs & Whatley, 2015). L'annotation désigne « toute forme d'ajout visant à enrichir une inscription ou un enregistrement pour attirer l'attention du récepteur sur un passage ou pour compléter le contenu sémiotique par la mise en relation avec d'autres contenus sémiotiques préexistants ou par une contribution originale » (Zacklad, 2007 : 34). Elle est intra-documentaire au sens où, en marge du document – ici la captation vidéo –, elle en est solidaire tout en proposant un enrichissement, un développement, un complément sur un point ou une séquence précise.

Plusieurs initiatives pour créer des applications dédiées aux besoins spécifiques des arts de la scène se sont développées récemment. L'un des axes exploré est la création de logiciels d'annotation vidéo avec de nombreuses approches, témoignant d'un rapport à l'archive et au document loin d'être univoque (Bardiot, 2015a ; 2015b).

L'approche inter-documentaire : connecter la captation vidéo

La captation suscite également une autre approche, qualifiée d'inter-documentaire (Briet, 1951 : 13). Dans le cas de la captation, l'approche inter-documentaire consiste à connecter le document vidéo à un ensemble d'autres documents (textes, images, sons, en ligne ou hors ligne). Ces « autres » documents permettent de combler les lacunes de la captation, d'élargir le cadre de l'image au contexte, au processus de création, à la parole de toute l'équipe artistique, à la réception du public, de préciser des aspects qui ne sont qu'évoqués. La captation ne devient pleinement intelligible qu'au sein d'un écosystème documentaire qui permet d'établir des correspondances, de corréler les informations, de mailler les traces, soit d'en révéler le contenu sémiotique. L'approche inter-documentaire souligne l'interdépendance entre les documents d'un même corpus ou « dossier documentaire ». Ces derniers ne peuvent uniquement se composer d'un ensemble de pièces cohérentes : il faut également établir des relations *entre* les documents.

Les *Dance Capsules* des spectacles de Merce Cunningham et les *Choreographer's Score* d'Anne Teresa De Keersmaeker sont deux exemples récents relevant d'une approche inter-documentaire. Au lecteur de réagencer les documents, de les articuler les uns par rapport aux autres, de trouver son propre chemin au travers d'un corpus hétéroclite et interdépendant, au travers d'un « dossier » dont la captation peut éventuellement être un élément saillant, mais jamais autonome.

Les capsules de Mémorekall

Approches inter-documentaire et intrad-ocumentaire ne sont pas exclusives l'une de l'autre et la frontière est parfois poreuse. Elles peuvent être utilement combinées et jouer simultanément de différents rapports au document, entre approfondissement et connexion. Elles offrent différentes strates de navigation à l'intérieur et à l'extérieur de la captation vidéo et permettent la réappropriation des corpus documentaires non seulement par les artistes et leurs équipes mais aussi par les conservateurs et le public.

Dans le contexte d'un projet plus vaste (Rekall), et avec le souhait de prolonger mes réflexions sur l'ingénierie documentaire liée à la conservation des arts de la scène via l'instrumentation informatique et le développement d'interfaces homme-machine, j'ai conçu en collaboration avec Guillaume Marais, Guillaume Jacquemin et Thierry Coduys une application en ligne, MemoRekall, mise en ligne en septembre 2015. *Open source* et gratuite, MemoRekall permet d'enrichir une captation vidéo en conjuguant les démarches inter et intra-documentaire, l'annotation et la connexion à d'autres ressources documentaires. Au fur et à mesure de la consultation le lecteur découvre annotations et autres documents, qu'il peut ouvrir et consulter à sa guise, pour revenir ensuite au film. Le temps structure l'ordre d'apparition documentaire, même s'il est également possible d'accéder aux différents contenus par leur organisation spatiale dans l'écran et de s'affranchir ainsi de toute chronologie. Le résultat est une « capsule » (nous empruntons le terme à Cunningham) qu'il est possible d'intégrer à n'importe quelle page web. La capsule comprend la captation ainsi que l'ensemble des annotations et des documents liés (ou des liens lorsqu'il s'agit de ressources en ligne). Elle offre une lecture augmentée de la captation au sein d'un environnement multimodal et peut être actualisée à volonté. L'élaboration d'un outil numérique tel que MemoRekall, et la réalisation de capsules à des fins de conservation, ont pour ambition de déduire de l'articulation des documents l'intention artistique de l'auteur de l'œuvre et d'aider ainsi à établir l'authenticité d'une ré-interprétation via la documentarisation.

L'interface comprend quatre espaces principaux : à gauche, une barre de menu, avec des boutons pour ajouter notes, documents ou liens vers des ressources en ligne, ainsi que quelques fonctions de paramétrages (choix d'un auteur et d'un titre, copyright, export en xml, code d'*embed* pour l'intégration dans une page web) ; au centre, la captation vidéo (provenant de Youtube ou Vimeo) et une *timeline* avec les points d'entrée des annotations et des documents connectés ; à droite, une colonne rassemble l'ensemble des documents liés par ordre d'apparition. Les documents peuvent être de n'importe quelle nature : textes, images, sons, vidéos. Ils sont téléchargés par le créateur de la capsule sur le serveur de MemoRekall. Les ressources en ligne sont disponibles sous forme de liens hypertextes et ne sont pas copiées sur le serveur de MemoRekall, dans le respect des droits d'auteur. Documents téléchargés et liens internet peuvent être annotés dans une fenêtre en pop up. Les manipulations s'opèrent directement dans le navigateur internet et sont sauvegardées automatiquement.

MemoRekall propose une lecture multi-documents, temporelle et spatiale, d'une œuvre, à partir de son enregistrement vidéo. Si cette application peut être utilisée dans de nombreux contextes, elle a avant tout été créée pour les besoins spécifiques du *time-based media art* et tout particulièrement des arts de la scène. MemoRekall se situe au carrefour de la valorisation de documents culturels numériques existants, de la création de contenus culturels enrichis et de la mise en place d'espaces critiques et collaboratifs. MemoRekall est à la fois un outil de création, de conservation, de critique d'art et de publication, offrant divers scénarios d'usages : conservation, exposition/publication en ligne, diffusion, médiation numérique, éducation aux médias... Il s'adresse à différents bénéficiaires, privés, collectifs ou publics. En fonction de chaque scénario, le statut et la nature des annotations comme des documents liés sont différents. Nous avons utilisé MemoRekall dans des classes pour familiariser les élèves (du collège à l'université) avec l'analyse de spectacle, dans des théâtres pour la médiation numérique des œuvres auprès de différents publics, avec des artistes pour documenter leur processus de création ou un spectacle achevé.

Binary Truths: Developing a Linked Data Model for Historiographical Arguments

M. H. Beals
m.h.beals@lboro.ac.uk
Loughborough University, United Kingdom

Introduction

This paper will argue that historical linked data should not be used solely as means of storing facts but also as a means of improving historiographical discourse by formalising rhetoric, clarifying premises and evidence, and allowing for a distant reading of historical interpretations.

The need for such formalizations can be seen in the following interaction between two historians. An argument is made by one historian with a selection of evidence to support it. Another historian responds with a counter argument and counter evidence. The first becomes frustrated; the second did not understand their argument and their new evidence is irrelevant. The second is equally frustrated as the first has not properly addressed their concerns and instead glosses over them to return to his or her original argument. To the outside observer the conflict appears intractable; neither side is willing to concede the other's points and modify their interpretation of the event or process. This is not a case of academic stubbornness; it is historiographical switchtracking.

Switchtracking (Stone and Heen, 2015) is the result of two similar but non-identical conversations taking place at the same time. In the above, both historians are discussing a single historical problem but have interpreted that historical problem in slightly different ways, responding to each other with own their interpretation of the question in mind. By leaving their specific goals implicit or relying upon ambiguous terminology they have allowed their arguments to be easily misconstrued or misidentified (Godden, 2013). For example, the historical problem "What caused the Salem Witch Trials?" might not only lead to different interpretations—community conflicts, economic disparity, rye-ergot poisoning, religious fanaticism—but also different incarnations of the question itself:

- "What were the causes of the Putnam accusation?" or
- "Why did the Salem Witch Trials begin with the Putnam accusation?" or
- "Why did the Putnam accusation escalate into a wider hysteria?"

The different interpretations that arise from these similar but non-identical questions can lead to historians speaking at cross-purposes and unnecessarily hinder our wider understanding of historical events. The simplest solution is to better define the premises and hypotheses of a given study. However, the challenge of providing a defined, testable hypothesis, combined with the semi-narrative writing style preferred by historians, often precludes this level of clarity. Limited by a perpetually incomplete evidence-base, fuzziness is assumed and allows if not promotes poorly aligned debates.

Linked data may provide a two-fold solution to this problem. Traditionally, clarity and reproducibility in historical research has relied upon three methodological pillars: the quotation, the citation, and the acceptance of interpretive interoperability. The first two work in tandem, providing clear links to or examples of the precise evidence used. Limitations of publishing space have previously reduced the comprehensiveness of these pillars but now the ability to provide targeted hyperlinks and sustainable datasets online allows for a much greater degree of precision. However, the use of page and line numbers, hyperlinks, DOIs, and other edition indicators are inconsistent across the history publications. Likewise, citation standards and allusion conventions differ between publications, subfields, and other communities of practice. It would be difficult, and arguably undesirable, to suggest homogeneity. Without this, however, it is impossible to prevent switchtracking and the misinterpretation as to which precise evidence is being used for which purpose.

The integration of a linked data layer, a meta-document attached to a piece of historical writing, could serve as a remedy to this problem. Bringing together existing ontologies for describing geographical, biographical, and chronological data as well as digital or digitised documents provides a straightforward means for creating strong, definite links between historiography and the data that underpins it. Because such a layer could vary in depth of detail, it could begin with the basic citation information expected of traditional footnoting, but flexibly add layers of detail that would be infeasible in traditional journal or monograph typesetting.

Linked data is already in common usage in certain historiographical and heritage circles, usually in the publication of discrete datasets or in cataloguing digital, digitised and traditional archive collections (Meroño-Peñuela et al., 2013). However, their integration with specific piece of historiographical writing is more complex. At their most basic level, they differ little from traditional citation practises and the added value of precision may not fully compensate for the additional effort in producing this metadata layer. Instead, it is the interpretation of that evidence, and the analytical linkages made by historians, that provide the most significant opportunity for developing historical research. Within the historical and heritage community, linked data is often considered to be limited to 'fact-based' information and cannot convey or represent the analytical frameworks that the narrative provides. Indeed, as of writing, there appears to be only one complete ontology for expressing rhetorical logic, which is poorly maintained with no clear evidence of it being employed in academic debate (Dumontier, 2014). Moreover, it focused upon highly structured logical expression; historical research often relies upon highly fragmented data, requiring vary degrees of informed speculation, which, when undocumented, is the primary cause of switchtracking.

Creating an ontology that can provide definite relationships between evidence, premises, correlations, causations, formal logical deductions and speculative interpretations would allow historians to maintain the semi-narrative writing style expected of historical research but add a layer of unequivocal—if less poetic—statements that provide unambiguous statements of their argument and its components. Beyond serving as a mechanism for researchers to refine their argumentation, presenting a complex historiographical interpretation as a collection of interconnected relationships—literal and rhetorical—would allow for a computational comparison of arguments; similar conclusions could have their evidences combined whereas contradictory interpretations would have a clear set of evidences and premises from which to begin an investigation of divergent views.

This paper will therefore discuss the issues surrounding the creation of an ontology that combines well established ontologies regarding historical evidences and document provenance alongside rhetorical relationships between premises and conclusions. It will demonstrate how one might create a graphical representation of a narrative text and vice versa. The paper will be presented in both semi-narrative long form and RDF triples.

The Pushkin Digital Project

Gabriel Belyak
gabriel.belyak@gmail.com
Saint Petersburg State University, Russia

The Russian academic approach towards editing of the nineteenth-century classics, in general, inherits German critical editing tradition. Typically, the edition will include three basic sections: 1) critically prepared definitive text of the work, 2) full critical history with the list of all the discrepancies between its versions 3) commentaries including a description of the manuscript and printed sources of the text, history of its creation, a detailed historical and literary commentary based on all the existing research about it, and finally explanatory notes to the text.

All the works of Dostoyevski, Chekhov, Turgenev and other XIX classics are published this way.O nly one of the 19th century classics still does not have his collected works academically edited. This exception is Pushkin, whose exclusive place in Russian culture can be compared to Shakespeare's in English, Dante's in Italian or Goethe's in German culture. The reasons behind this phenomenon are simply historical. The first attempt to publish a complete critical edition of Pushkin's works was interrupted by the revolution and the civil war, and the second was distorted by the personal order of Stalin. The third attempt is being carried out now, when the government's interests disregard any cultural values. The work towards finally making this edition is conducted at the Institute of Russian Literature of the Russian Academy of Sciences (Pushkin House). Today there are only four volumes published but the amount of copies is 500 in average, and they are marketed almost exclusively in St. Petersburg and Moscow.

The theme of this conference is Access. Low availability of any printed edition today can be easily compensated by publishing it online. However, when we speak about critical editions, the problem of accessibility obtains an entirely different aspect. To use all the information the existing critical edition of Pushkin's works provides, its readers should have a special philological training. and if they have one, in order to actually conduct any work with the materials provided they will require access to Pushkin's autographs, books, magazines of the Pushkin's era and to all researches and papers upon which the commentaries are based. And it goes without mentioning that readers are expected to have a grasp of the main cultural realities of Pushkin's epoch, and to be aware of Pushkin's social and political surroundings. All this makes an anticipated number of readers for this edition only slightly higher than the number of experts who participated in its preparation. Unfortunately, all this can be applied to almost all annotated critical editions. Yet it is obvious that the information they contain can be interesting and useful for every reader. The question is how to make academic publication available for everyone without compromising the scope and depth of its material? And that is the main challenge that stands in front of Pushkin Digital Project.

Developing this project we were thinking not only about how to publish Pushkin's manuscripts, their decipherment and critical descriptions along with the text and the commentary; our ambition was to create an edition that unlike its prototype, which required a certain scientific competence of its reader, would, on the contrary, be able to form such a competence. Our electronic publications were to be addressed not only to researchers and students, but to anyone who would like to have a deeper look into Pushkin's world.

To accomplish that goal, we chose a simple and understandable architecture, consisting of three main operational modes: Text - Commentaries - Manuscripts. Each of these three sections has an autonomous meaning, and could be the sole object for a special digital edition. However, within the framework of our project, it was imperative for all three parts to be closely linked and cross-referenced creating an informational entity, where the text, its history and its context are inseparable from each other.

The Text section of the edition contains the definitive text of the work with two main interacting tools. One tool gives the user the ability to read all the commentary notes upon the text (which may include some external links to music associated with the text and images relevant to this fragment). The other shows all the lines that had any variations along the creation of the text and links to the digitised sources of these variations in section Manuscripts.

The section Manuscripts is a digital representation of autographs and/or printed sources with full transcription and the estimated chronological sequence of author's editings. When working with Pushkin's manuscripts, the presence of a full transcription has a special value due to the extreme intricateness and illegibility of Pushkin's drafts (less than a dozen specialists in the world are able to read it). This section contains a detailed paleogeographic description of each manuscript together with the history of its creation.

The Comment section - is the most voluminous section of the website. Academic historical and literary commentary on Pushkin's works is formed as a reflection and synthesis of all existing studies upon the subject (there is a special department of the Pushkin House dedicated to accounting, describing, and cataloging every book referring to Pushkin or his works (there is no digital version). In the paper edition, this section appears as a coherent and undivided text sometimes up to hundreds of pages. Without knowing its structure and contents in advance, an unprepared reader will easily get lost in it,, and this is if the reader wasn't already scared away by the scientific language in which the text written. Therefore, the digital version of this section was not only rewritten but also splitted into smaller thematic divisions, to allow the reader to navigate easily through all available material and to find quickly what he was looking for. Another problem of the paper edition was a wast amount of proper names, titles and concepts encountered in the commentaries,the meaning of which could be unknown, so that the commentaries themselves needed to be annotated. For the sake of educational functionality, they were to be expanded with an array of background information presented as hyperlinks. That enabled us to engage the full texts of the studies (articles and books), the material of which was reflected in the commentary, as well as those literary texts (including rare editions of XVIII-early XIX century), that the commentaries indicated as significant to the main text. After finally adding audio, different illustrations, and explanatory materials for all the names, facts and places that may be unknown we came from digitising a specific edition of Pushkin's works towards creating an academical encyclopedia for each text included in it.

An encyclopedia of this kind not only extends the perception of the unprepared reader, gradually luring him or her further and further towards the development of the material and teaching a scientific approach towards the text, but at the same time it provides a specialist with all the background and tools required for further studies. Thus, the problem of access to academic publications is solved not in one but in two of its aspects: providing both accessibility and apprehensibility (obtainability) at the same time.

In conclusion, we would like to underline that everything written above is a description of a developing project. At the moment, we have only four dramatical pieces available on our website (the so called Small tragedies). How long would it take to prepare a publication of Pushkin's complete works, we do not now. But in this process, we will certainly face many new problems, which on the larger scale can be described as finding an adequate digital equivalent for different pieces of academical knowledge. To accomplish that task or at least to find a proper vector towards it, it is imperative to become a part of the DH community whose main concerns are in the same field.

Using Methods of Computational Linguistics for Resolving the “Homeric Question”

Abstract

The 'Homeric Question' today is no longer a question about Homer as a person, but a question of the genesis and history of the early Greek epic texts. It is still unresolved. Three mutually incompatible Homer theories (Analysis, Neoanalysis and Oral Poetry Theory) compete, which are based only on manual selections of the text, and this fact seems to be part of the problem. In this paper, we report on the development of a toolbox providing methods of computational linguistics intended to improve our capacity to examine texts in their entireity.

Introduction

The Greek epics, traditionally associated with Homer and Hesiod, play a special role among the early texts of Europe. Not only does European literature begin with these poems, but they also mark the transition from oral tradition to written texts. This intermediate position poses very special problems to every philologist, which are best known under the name 'Homeric Question' (going back to Friedrich August Wolf's Prolegomena ad Homerum, 1795): Have these texts been orally composed and later written down (as Oral Poetry Theory claims)? Or are they poems written by a single great poet experienced in oral tradition (as Neoanalysis maintains)? Or do they combine different passages stemming from different times and poets, compiled later (as Analysis assumes)? The core question is: How can we know?

All three theories present evidence for their findings, but this evidence consists of preselected material – obviously selected according to the principle to present what fits best to the own theory. In order to improve our view, it is useful to look at the complete data instead. That is why as early as the 1970s, the University of Regensburg launched a computer aided project aiming at providing the linguistic data needed for an overview. The project was founded by Ernst Heitsch and Xaver Strasser, and its conception and aims are precisely described in Strasser's dissertation thesis (1984).

Oral texts (as we know from Parry, etc.) are constructed not from single words (Lemmata), but from repeated word connections, which the oralists call 'formulae', but a neutral observer would better call 'iterata' (= lat. 'repetitions'). It has been known that repetitions are a key component of testing Homer theories since the 19th century, but at that time there was no reliable way to collect all of the required data. The Regensburg Project created the first complete directory of Epic repetitions (iterata), based on a lemmatized concordance of all Epic word forms. In the "Regensburger Iteratenverzeichnis" (RIV), which is still unpublished, 'iterata' are defined as semantic and syntactic meaningful phrases that occur at least twice in the corpus. It is e.g. possible a) to find passages that are interlinked by the usage of the same iterata throughout the corpus, and b) to have meaningful information about the usage (e.g. frequency, compactness) of words and phrases.

Therefore, the RIV offers the possibility of collecting and presenting all iterates of a certain type, i.e. of specific frequencies or distributions over the epic texts.

The new possibilities have been used for collecting and researching a complete group of iterata: the so-called 'Singulaere Iterata der Ilias', i.e. those repetitions which remain unparalleled in the Iliad. The results have been published in four dissertations (Ramersdorfer, 1981; Csajkas, 2002; Blößner, 1991; Roth, 1989). This group of repetitions is of special interest, because the *Iliad* is the largest and (according to common opinion) oldest of our epic texts. Therefore, an Oral Theory would expect that it is very small, because why should 'old formulae' be so rare in our oldest and largest text? However, this group contains 3,739 Iterata (out of 18,961 Iterata in sum), and in addition, linguistic and semantic research gives evidence in many cases that Oral Theory assumptions do not really explain the facts. It looks as if the claims of the Oral Theory are fundamentally based on (wrong) generalizations of some (correct) results. But also the Neoanalyst position is weakened by demonstrations that, in some hundred cases at least, passages of the *Iliad* presuppose the knowledge of 'younger' texts. These results do not only diminish the weight of widely spread theories, but offer concrete data on which new, and more reliable, theories can be built (cf. Blößner, 2006).

Since these examinations, the methods of Computational Linguistics have improved a lot as has the processing power of today's computer hardware. This paper presents an approach to finding further subsets of iterata that continue and extend the idea of improving Epic theories.

Extending the idea of the 'Singulaere Iterata of the Iliad'

The search aims at finding passages in the text which react to each other. With these results, existing theories can be tested and better ones can be built.

Searches of this kind are applications of the scholars' implicit knowledge. So in order to be able to create a computer assisted system this expert knowledge has to be transferred to describable rules and algorithms. The idea of the 'singulaere Iterata', e.g., defined a "conspicuousness" of a phrase that has an unexpected distribution (contrary to the expectation of some theories). This heuristic was proven valid by the results of the four dissertations mentioned above.

Next we will present some ideas that have a well-known foundation within Computational Linguistics but also can be seen as an extension of the 'singulaere Iterata' idea.

The SIoI compares frequencies between two corpora, the Iliad and the complete corpus but the Iliad, where one frequency is very rare (one). So it can be seen as a subset of the **frequency list comparison**, which searches for terms that differ largely between two (or more) corpora. This method uses the frequency class which for a given corpus *K* and a term *t* is defined as

$$HK_t^K = \left\lfloor 0.5 - log_2 \frac{freq_t^K}{freq_{\alpha^K}^K} \right\rfloor$$

where $freq_t^K$ is the frequency of *t* in *K* and α is the most frequent term in *K*. Now one could search for Iterata *I* where

$$HK_I^{notIliad} \gg HK_I^{Iliad}$$

which obviously extends the SIoI.

With the method of the frequency list comparison one could especially search for iterata that are rare in the *Iliad* but frequent outside of it, but it is hard to decide whether they are of significance regarding the search for parallel passages. So we could use the density of the occurrences outside of the *Iliad* as a filter for this class of Iterata. A well-known metric for this question is the **Chi-squared** test which for partitions *R* (e.g. overlapping passages of 300 verses ignoring book boundaries) of a corpus *K* and an iteratum *I* is according to (Rayson et al., 2004) defined as:

$$\chi_I^2 = \sum_R \frac{\left(freq_I^R - exp_I^R\right)^2}{exp_I^R}$$

A high Chi-squared value now suggests that this iteratum is compact in the sense that many of its occurrences are close to each other in respect to the overall corpus.

Another approach to a density filter is the **log-likelihood-ratio** as proposed in (Dunning, 1993) that according to (Moore, 2004) is also valid for rare events (in this context iterata with low frequency). For partitions *R* of a given corpus *K* and an Iteratum *I* it is defined as:

$$\begin{aligned} sig_I^{R,K} &= 2 \cdot \left[\left(freq_I^R \cdot \log \frac{freq_I^R}{exp_I^R} \right) + \left(freq_I^{K/R} \cdot \log \frac{freq_I^{K/R}}{exp_I^{K/R}} \right) \right] \\ exp_I^R &= freq^R \cdot \frac{freq_I^K}{freq^K} \\ exp_I^{K/R} &= freq^{K/R} \cdot \frac{freq_I^K}{freq^K} \end{aligned}$$

Again the expected occurrences of an iteratum in a given passage are compared to the actual frequency. But also the same metric is applied to the rest of the corpus aside from the considered passage. Again a high log-likelihood-ratio value indicates that the iteratum is compact in this passage. Also it is possible to find passages where an iteratum is more frequent than expected.

An issue may arise as this metric is rather complicated from the perspective of a scholar in the humanities and it remains to be well explained; issues like this have been addressed in the ”ACID for the Humanities" of the DARIAH project (Büchler, 2013) and also in the conclusions of Bestgen, 2013.

First results and conclusions

The ideas presented above have been fully implemented, and this implementation has been used in first applications. It has been suggested to use the Chi-squared test and log-likelihood-ratio to test the validity of an assumption of the Oral poetry, which says that the singer could choose freely from a given set of phrases while performing. This should lead to a rather equal distribution of highly frequent terms. Using our implementation, first results raise concerns regarding the validity of this Oral poetry thesis as the analysis shows that there are many high frequency Iterata that are also “compact” in some parts of the works. Further and more philological work has to be done by analyzing those iterata to find out whether there are semantic reasons for this, and to be able to explain the passages that differ strongly. In general, we expect that the further development of our implementation and its application to different theses proposed by the Homer theories will lead to new insights into the problems named the 'Homeric Question'.

Rewards: Books, Boundedness and Reading in Participatory Culture

Kathi Inman Berens
kathiberens@gmail.com
Portland State University, United States of America

As a professor whose appointment encompasses both electronic literature and printed book publishing, I think a lot about interactive reading and reward systems. Reward systems are fundamental to videogames, where the consequences of reader/gamer choice materialize the stakes of interpretation (Juul, 2005). Computational reader response critics like Bell, Ensslin, Bouchardon and Saemmer frame their discussions of reading as medium-specific and, as I have argued, device specific (Berens). This emergent subfield is "literary interface criticism" (Pold), informed by comparative textual studies (Hayles and Pressman), performance studies (Fletcher), and interface criticism (Galloway; Critical Code Studies Working Group; Chun).

The book publishing world is only now, in the age of mobile-first web access, beginning to reckon with the implications of readers' daily exposure to pervasive, quotidian experiences of interactive reading and gaming environments in video games and social media. These entail nonhuman disruptions in the value chain of traditional industrial book production and distribution. John Maxwell observes that "large swaths of DH [digital humanities] practice overlap or are adjacent to practices in [book] publishing (e.g. markup, database design, user experience design, editing), yet publishing studies and the digital humanities often appear to run at right angles to one another. There is surely an opportunity for complementary work here." My object in this talk is to articulate points of contact between DH and book publishing. Literary interface criticism offers a window onto interactivity and reward systems that extend how we understand the actions of reading: physical, cognitive, social. A book's medium-specific affordances (random-access device; portable; cheap; no Digital Rights Management) are attractive. But how might books take advantage of digital interactivity to provide more rewarding interaction than the "reflowable content" of an e-reader platform?

"Playable books"—the subject of my monograph-in-progress—are part of the "complementary" space Maxwell identifies between book publishing and DH. A playable book is a story object that can be held in human hands, requires physical interaction between human and computer to render, and outputs a story experience that can be "bound" or is otherwise finite. A printed book with interactive elements is playable (see, for example, Tyehimba Jess's *Olio* and Zachary Thomas Dodson's *Bats of the Republic*); a novel displayed on an e-reader is not; an improvised, participatory story in social media is not. (My monograph situates playable books in both literary games and fanfiction archives and databases: such situation is beyond the scope of this short paper–see Note).

In this paper I compare reading's reward structures in one bestseller and a popular, socially dynamic e-literature. I suggest how physically playful digital interactivity could inform mainstream book production and marketing. *Selp-Helf*, a 2015 *New York Times* bestselling book published by Gallery Books (an imprint owned by Simon and Schuster) is a successful YA [young adult] title. It is designed for hands-on, playful interaction; and its author, YouTube sensation Miranda Sings [Colleen Ballinger] sparked such a successful pre-sale campaign that her book débuted at #1 on the *Publisher's Weekly* Nonfiction Hardcover list, and #1 on the *New York Times*' Advice, How-To and Miscellaneous list, where it remained for eleven weeks. But *Selp-Helf* is just one piece of a successful transmedia campaign spanning a Netflix series *Haters Back Off*, a fifty-seven city comedy tour, and several musical albums. Interactivity, in this case, is spread among various media. Book publishing gets a small slice of the pie.

How might mass market book publishing increase its relevance in the contemporary media ecology? I present a short reading of *Ink After Print* (2012), an interactive story machine installed in public spaces such as a rock festival and public libraries, as a way of suggesting what next-generation story interactivity could look like for book publishers who currently funnel their social activity around book into social media campaigns they don't own, because they are hosted in platforms that dictate the terms of interactivity and serve their own agendas. A book like *Selp-Helf* has potential to benefit from reading rewards that are materialized in the book interface itself rather than a paratextual social media campaign.

Rationale & Analysis

Ink After Print is a full-body, playable literary interface. Exhibited at rock festivals, public libraries and train stations (in a French copy of the Danish original), *Ink* brings full-body haptics to the unbound book in ways that resonate with the embodied online social marketing of YA [young adult] titles. Both *Ink* and *Selp-Helf* ask the reader to do real things in the world, and leave traces of those activities in the literary interface, whether it's navigating through the sea of words in "Ink" and printing the results, or posting photos of oneself when meeting the YA author, or dressing up as a character (in this case, teen girls dressing as Miranda Sings.)

In both cases, writer/readers or "w/readers" (Landau, 1999) are having authentic experiences with literary interfaces. "Spreadable media" (Jenkins, Ford and Green, 2013) is a byproduct that empowers Ballinger's fans to use her book as a springboard to articulate their own perspectives on identity and gender. Use of digital skills is the precondition for fan interaction. Jenkins reminds us that *audiences* are individuals, "produced through measurement and surveillance, usually unaware of how the traces they leave can be calibrated by the media industries." *Publics* are collectives that "actively direct attention onto the messages they value" (166). An entire subculture of book fans—often of young adult literature—is using books as totems around which to build worlds made by and through participatory media; *Selp-Helf* is one strong example. *Selp-Helf* and other YA books like it are centerpieces of book-specific media microecologies with particularized rules of conduct, aesthetics, and dynamic interaction. "Playability" focuses through the book, but exceeds the bounded dimensions of the book itself.

As more book marketing focuses on live events captured for and refracted through social media, this paper proposes that book interactivity should do more to engage the actual practice of reading to draw audiences into memorable relationships with the works. Analysis will focus on how the physical aspects of unbound book reading disclose new quantitative and qualitative shifts in mass market book reading practices.

Book publishers, loathe to develop content that they can't expressly monetize, run cheap social media campaigns in platforms they don't own like YouTube, Twitter, Instagram and Snapchat. That's where book publishers should look to literary experimental pieces like *Ink* for how to create "eventness" (pace Bahktin) around distribution and play beyond social media. This would involve investment in digital-first book design and possibly a reading apparatus that could be physically moved location to location. Such techniques could scale, having a few select interactive reading "shows" that are captured in and for the social media audiences. Book publishers have built the expectation among YA readers that social media is their gathering space. Following the example of *Ink After Print*, publishers could offer actual, embodied, interactive reading experiences.

Ink After Print provides a rich context for readers to experiment with their affective experience of boundedness. The mechanics of *Ink* gameplay are sufficiently challenging that readers might feel a sense of reward in assembling a poem using the hand-held "books"; in this sense, the printed receipt is token of achievement. But it is also a highly portable object and a potential gift: to the ephemeral community of others playing *Ink After Print*, where you can share your poems with others who have played; and to the virtual community where Ink "receipts" are stored in the blog. When I curated a media arts show and exhibited *Ink*, I observed readers also folding their receipts into small objects that they then shared with others. The untrackability of what people do with their *Ink* "receipts" stands in stark contrast to the databased traces of participation left by fans of *Selp-Helf*. While *Ink* does output to a blog, its outputs focus on the words themselves, not the user identity. In this sense, *Ink* resists the types of identity quantification that feeds and funds corporate sponsorship of social media platforms.

Note

[1] Working groups of note in this space are: the Games and Literary Theory group founded by Espen Aarseth, and the Critical Code Studies Working Group. Books of note: Astrid Ensslin's Literary Gaming; Timothy Welsh's Mixed Realism: Videogames and the Violence of Fiction; Anastasia Salter, What Is Your Quest? From Adventure Games to Interactive Books; the excellent collec-tion Analyzing Digital Fiction, edited by Alice Bell and Astrid Ensslin. Alice De Kosnik's Rogue Archives, and Amy Earhart's Traces of the Old, Uses of the New discuss the effect of fan archives and tribute sites that (as Earhart shows) are subject to abandonment, decay and obsolescence.

Classifying aesthetic forms – a methodology at the heart of art history

The transformation of aesthetic styles has been at the heart of art history since its inception as a scholarly discipline in the late eighteenth century. Analyzing the single artifact and the carefully curated corpus have been the techniques for crafting hermeneutic understanding for such processes of change. Recently new instruments based on statistical techniques empower us for a fresh take on bodies of sources once disregarded as second tier complementary sources such as for instance very large corpora.

The Neoclassica research framework

The *Neoclassica* research framework (Donig et al., 2016) was conceived to provide scholars with new instruments and methods for analyzing and classifying artifacts and aesthetic forms from the era of Classicism (ca. 1760–1860). The neoclassic movement was of almost global scale—affecting architecture and design from Sidney to New York, and from Athens to the outreach of the Russian Urals—while relating to a common reference in classical antiquity, therefore making it an ideal topic for studying processes of stylistic transformation.

It accommodates both traditional knowledge representation as a formal ontology and data-driven knowledge discovery, where cultural patterns will be identified by means of algorithms in statistical analysis and machine learning, having in particular the potential to uncover hitherto unknown patterns in the source data. The outcomes of the top-down and the bottom-up approach will be united in a consistent, unified formal knowledge representation.

Motivated by the need to combine object classification with domain knowledge representation, the ontology focuses at the moment on artifacts (in particular furniture and architecture) and their components. Following the preliminary hypotheses that aesthetic forms in furniture and architecture are in closest communication with each other due to constructional commonalities and their shared reference of the Classic, we decided to start developing the knowledge discovery module of *Neoclassica* by classifying artifacts in digital images.

Knowledge discovery

In this paper, we report on our efforts for using deep learning for classifying artifacts in digital visuals. We chose a deep learning approach for our classification method because of its current superiority over other methods and still rising accuracy over the last years in nearly all image classification and object detection challenges.

Initially, we compiled a body of images both from commercial sources such as auction houses, antique dealers and other public sources. Due to the complex copyright situation, this corpus can not be redistributed. In order to make our experiment reproducible and since the *Metropolitan Museum of Art* (MET) has released 375,000 images in the public domain (The Metropolitan Museum of Art, 2017). we assembled a corpus of 379 artifacts relevant to our research. We processed this corpus with the same algorithm as the original proprietary corpus and released the data together with the source code (The Neoclassica Project, 2017).

Classifier description

The main classifier for our experiments is a *Convolutional Neural Network* (CNN). It classifies an input image as a whole.

In a first step, we applied a standard implementation of a CNN (namely *VGG19* (Russakovsky et al., 2015)). The results were not satisfactory for our needs. It classified the type of the object depicted in the image with an accuracy of 0.37.

In a second step, we opted to employ pre-training, a common technique for improving accuracy in neural networks. We experienced that available pre-trained classifiers for generic image classification proved ineffective in our case. Most of them are trained on a specific subset of *ImageNet* (Deng et al., 2009), containing 1000 classes. These classes are broadly spread around everyday objects like dogs and planes. This led us to assume that the amount of very different classes that don't occur in our corpora interfere with the classification. Following that hypothesis, we decided to train the algorithm on a specific subset compiled from *ImageNet* mainly containing different furniture objects like tables, chairs, and cabinets. They sum up to 35,000 images. The first training step with these images resulted in an accuracy of 0.54 of classifying the object correctly.

First layout

The first corpus contained 2,129 images representing 300 European period artifacts mostly in a colored format of highly diverging quality and resolution. They depict the objects fully, partially or are close-up shots of specific forms. We coarsely annotated these images by manually labeling them on the level of folders. The concepts applied during this labeling process are directly taken from the *Neoclassica* ontology and describe concepts for types of artifacts. These concepts were derived from period sources.

The depth of the class hierarchy was partly reflected by the folder structure. The folder labeled "Chest of drawers" contains all instances of this class. Their labels in turn reflect the names of all the sub-classes in the most extensive specification (e.g. semainier, Wellington chest, commode scriban).

After pre-training, the next step was fine-tuning with this corpus. The accuracy was 0.44, the F1 measure 0.44.

Second layout

The second corpus was assembled from open data released by the MET. It contains 1,246 images representing 379 European and American period artifacts ranging roughly from 1780–1840 including some transition pieces, drawings, and prints. They also depict the objects fully, partially, or are close-up shots of specific forms. We used the titles provided by the MET and manually aligned them with the *Neoclassica* ontology.

The overall mean accuracy over all classes was 0.36, the F1 measure 0.21. For the computation of these numbers, all results that are non-computable (due to only having one image in either the train or test set) were removed. These low numbers result from the existence of two many artifacts represented by only one image, thus making a split in training and testing data meaningless. However, applying pre-training using same *ImageNet* corpus as in the first layout yielded a mean accuracy over all classes of 0.59 and a F1 measure of 0.58.

In order to achieve better results and since the classifier classifies the image as whole, we excluded all images that did not depict the whole artifact. We kept multiple copies of the same image if they were used to describe a different but similar object. We split the images depicting multiple objects so that the resulting images represent only one artifact. We also processed these images so that neighboring objects were covered with solid colors. The images that could not be split (e.g. room interiors) were excluded from the corpus.

Using the same settings with the curated corpus and with pre-training we achieved an accuracy of 0.77 and an F1 measure of 0.76.

Challenges

While pre-training and improving the curation process helped us to raise the accuracy, we assume that there is room for improvement.

Parameters to be taken into consideration include the small size of corpora and how to overcome this limitation since this limits the effectiveness of a neural net. Additionally, since pre-training has been proven to enhance the results, it is rational to assume that a pre-training corpus better suited to period artifacts would improve the results further. Third, our experiment was affected by the limitation of the standard implementation of the CNN which classifies the image as a whole and not parts of it.

Outlining parts inside an image and classifying them is a difficult task for machine learning methods. Recently, a new type of neural net emerged that tackles this challenge: *Regional CNN* (RCNN). It is implemented most prominently in an algorithm called *MultiPath Network* (Zagoruyko et al., 2016).

Current improvements: Using a Regional CNN

We are manually annotating regions within the images with classes from the ontology for training a RCNN that locates objects.

The implementation of the RCNN is divided into two steps. First, it detects objects in the image and draws their outline as a polygon. The second step is classifying the outlined objects using the included standard CNN.

Preliminary results of *MultiPath Network* with default pre-trained settings show that the first step of the RCNN already outlines objects in our corpora within reasonable limits. The corpus for pre-training is *COCO* (Lin et al., 2014). Naturally, specific domain objects are not located and the class names are too generic. For our purpose, fine-tuning on a custom annotated corpus is essential. An RCNN requires a more detailed corpus. The exhaustive task of manually draw the objects' outlines within an image promises higher quality in locating objects (first step) and is necessary to classify the objects according to the ontology (second step).

Future work

We decided to take two steps in the near future for improving our results.

First, we are compiling a new corpus to train the RCNN with, avoiding pitfalls like inconsistent quality, heterogeneous image rights and an inadequate distribution of image per class. Here we would like to go a dual approach. Together with domain experts, we intend to collate a corpus from the large repository of a major auction house, providing us not only with a selection of artifacts' images but also with texts to be used in multimodal analysis.

On the other hand, this kind of artifacts may exhibit provenance issues (e.g. heterogeneity or lack of provenance). We will thus compensate for such issues by digitizing a major corpus of neoclassical artifacts forming an ensemble and comprising artifacts in multiple modes having evolved in close reference to each other. Therefore, we have entered a partnership with the Dessau-Wörlitz UNESCO world-heritage site, an almost untouched complex of manor houses and their furnishings in early neoclassical style.

Regarding the annotations, we are developing our own semantic annotation and ontology population tool since January 2017. The tool will create an annotated corpus. The actual annotation process will be conducted in cooperation with emerging domain experts from the chair of Visual Culture and Art History at the University Passau.

A Database of Online Book Response and the Nature of the Literary Thriller

Peter Boot
peter.boot@huygens.knaw.nl
Huygens ING, The Netherlands

Introduction

The study of literature has traditionally focused on the literary work, and sometimes its author, rather than on the response that works evoked in their readers. The arrival of the computer in the study of literature has not really changed that – perhaps unsurprisingly, as reader response has never been systematically recorded. The fact that readers have begun to document their reading and reading response on websites is therefore very fortunate (Gruzd and Rehberg Sedo, 2012, Maryl, 2008: 390-406). Booksellers' sites such as Amazon and review sites such as Goodreads, as well as weblogs, forums and general-purpose social media sites provide access to first-hand reading reports. Though most research on these sites focusses on (behavior of) users (Nakamura, 2013: 238-243, Thomas and Round, 2016: 239-253), we are beginning to see them being used in literary research (Finn, 2011) .

This paper presents the Online Dutch Book Response (ODBR) database, that was designed to facilitate research into book response. At present, the database holds reviews and other response items from an online bookseller as well as from four Dutch-language mass review sites, including, where available, the information about books, reviewers and sites necessary to put the reviews into context.

To show one type of research that the database supports, the paper displays a clustering of reviews by genre, based on frequently used words. I discuss the clustering and what it suggests for further research.

Content: mass review sites, reviews from booksellers' sites, weblogs

While the ODBR database was designed to hold any kind of (online) book discussion, at the moment it holds 280,000 response items from four mass review sites: three from the Netherlands (hebban.nl, dizzie.nl and watleesjij.nu) and one from Flanders (lezerstippenlezers.be). It also holds 313,000 items from the main online bookseller in the Netherlands, bol.com, and 36,000 brief expert reviews. We are currently working on downloading about 400 book blogs.

Mass review sites are sites where the main focus is on book reviews uploaded by the sites' users. The best known example is Goodreads (goodreads.com) (Thelwall and Kousha, 2016: 972-983). Hebben.nl, for example, is currently the largest mass review site in the Dutch-language area. It is in many respects like Goodreads: users post reviews, they can follow other users and they can create book lists. Other users can respond to the reviews or vote them up or down. There are moderated reading clubs on specific books. Apart from the user-contributed content, Hebban also holds a fair amount of editorial material, among other things expert reviews, blog posts, interviews and giveaways.

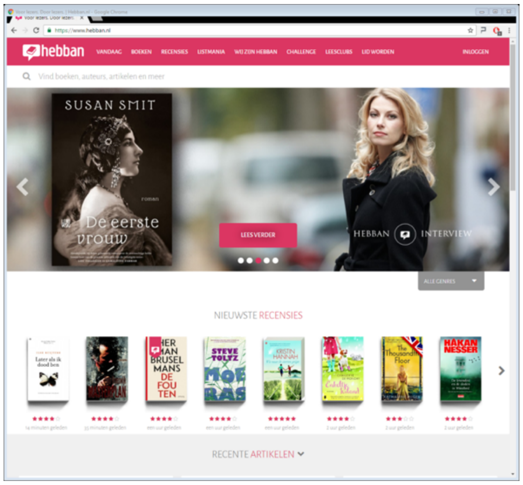

Figure 1. Front page of Hebban.nl

The other three sites are largely similar. Lezerstippenlezers.be ('readers tip off readers') is somewhat simpler in that it lacks the social functions of the other sites. Noteworthy about dizzie.nl is among other things that the site was downloaded for inclusion into the ODBR database only days before it was closed down. The site administrators explicitly stated in their final announcements that no archive would be kept. The ODBR database may be the most complete record of the site's existence. Since then, watleesjij.nu has also been closed down.

Database design and content

The purpose of the database is to facilitate research into online book response. It should be able to store the response texts as well as information about the response's context. Response items are not just reviews. They include book lists, expert reviews, blog posts and review responses and other response types. Ratings and tags are also stored in the database. Figure 2 shows the main entities in the database.

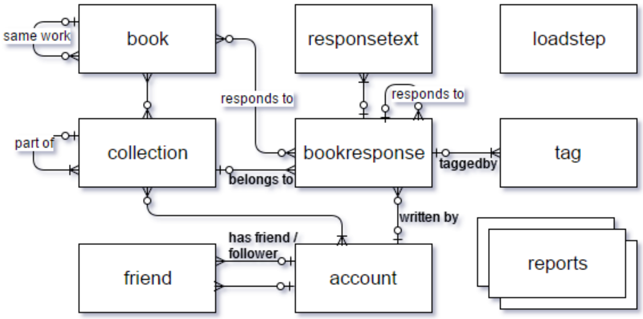

Figure 2. Main entities in ODBR database

The database now contains the following numbers of records: 146,800 books, 58,000 user accounts, 40,000 friendships/followers, and 628,800 book responses. The types of the responses are given in Table 1.

Article type	Number
article	4584
articleresponse	7445
blog	6122
blogresponse	2536
bookdesc	149002
expertreview	36634
list	10280
listresponse	2380
PM	14021
quote	3389
review	382998

Table 1. Article types in ODBR database. PM: private message; Bookdesc: book descriptions provided by sites. The 'response' items (blogresponse, etc.) are responses to a response: a blogresponse is a response to a blogpost.

This large collection of book response items and context information creates many different possibilities for research. First of all, the response texts facilitate the investigation of response to individual books, authors and genres. The texts show the norms that readers apply as well as the way reading affects them. The availability of expert reviews alongside general readers' responses creates the possibility to study differences between (semi-)professional and lay reading. Other types of content enable different lines of research. Information about friends and followers can help investigate the influence of the social environment in reading choices and book appreciation. As many writers use the book review platforms to get in touch with their (potential) readers, the collected data can also provide insight into their marketing strategies. Information about the book lists that readers create (for instance 'to read', 'read in 2014') shows which books are perceived as similar, prompting the question whether they will also be rated similarly. The integration of the discussions and the context information from multiple sites in a single environment that facilitates integrated querying is something that, as far as I know, has not been done before.

Unfortunately, because of copyright and privacy concerns, the database is not accessible over the web. Researchers who are interested in accessing its content are asked to contact the author.

Clustering by genre

Of the research possibilities that the ODBR database offers, here I discuss just one example, an investigation in the word use in reviews by genre. This is an interesting subject, as word usage can be considered as an indication of how people respond to books. I will show a clustering of the genres by word use, which should give a first indication of which genres are perceived by readers as similar.

Dutch publishers use a shared system for classifying their books. This so-called NUR code (an abbreviation meaning Dutch-language Uniform Categorization) covers aspects of format as well as genre. On some of the downloaded sites, books were assigned NUR codes. As the load process of the database tries to merge the book information from multiple sites, NUR codes are available for 75% of the reviews. In the computations, reviews were merged by NUR code. Relative frequencies were computed for all words, these frequencies were then transformed into z-scores. The Euclidean distances between the frequency vectors for the 200 most frequent words were computed and formed the basis for the clustering dendrogram in Figure 3. The figure only shows NUR codes for which there are more than 500 reviews available. For other choices for most frequent words and distance measure, the clustering is largely similar.

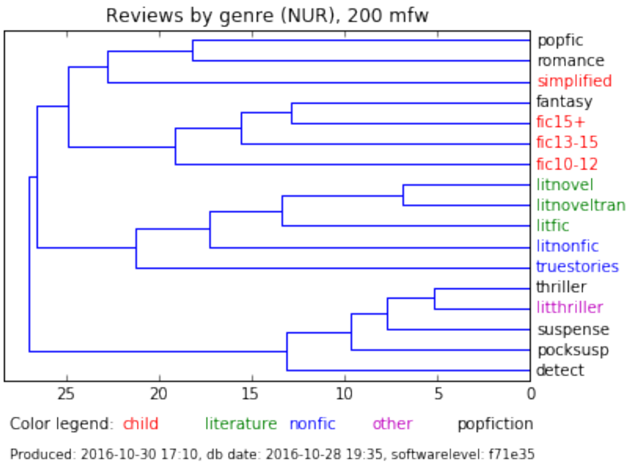

Figure 3. Dendrogram of NUR codes, based on distances between word usage in the corresponding reviews. The colors of the NUR labels reflect a higher-order grouping of genres (see legend)

A number of interesting groupings appear: the literary novel, original and in translation, groups nicely with other literary fiction. At a higher scale literary fiction groups with literary nonfiction and, interestingly, with true stories. Fantasy groups with youth literature, maybe a reflection of its popularity among younger readers. A group of general popular fiction and romance is also close to youth literature. Perhaps the most remarkable in the clustering is the location of the literary thriller. It sits squarely on one branch with the other suspense books such as the regular thriller and the detective. Those who doubt whether the 'literary' in the literary thriller is more than a marketing label, will see their views confirmed by this clustering.

Looking for an explanation, we can drill down to look at the individual words underlying the dendrogram and see for example how readers of (literary) thrillers talk about plot and plot lines, as one would expect. They also speak about 'main characters'(plural), while people who discuss literature use the singular 'main character'. That suggests an interesting difference between literature on the one hand and (literary) thrillers on the other. To praise a book, readers of literature use 'beautiful' and 'nice', readers of (literary) thrillers use 'good' or 'great'. For other observations I am still looking for an explanation. Why, for example, do people who discuss literature use more personal pronouns? That question, like many others, requires further investigation.

Conclusion

Until now, most humanities-oriented researchers that have worked on online book discussion sites and communities have taken a qualitative approach (Fister, 2005: 303-309, Foasberg, 2012). The ODBR database is meant to facilitate quantitative research into online book discussion and, through the lens of online book discussion, into literature, both with respect to its effects on readers and as a social phenomenon. The rich data model and the large quantity of available data should provide support for both language and network oriented research approaches.

Libraries and Digital Research: Sharing the Incubator

As humanities scholars embrace digital research and more content is digitized, tools and methods such as text mining and spatial analysis become increasingly more vital, especially to graduate students who are at a formative stage in their careers. Librarians and library staff are keen to support these researchers and meet the growing demand. To address this demand, UCLA librarians developed DResSUP (Digital Research Start Up Partnerships), a six-week summer program designed to create partnerships between library staff and researchers. At our institution, a core group of library staff have the expertise to engage with digital research projects beyond the initial phase of data discovery. Therefore DResSUP was initially built around this core group, allowing us to build a local community of practice and test our capacity for supporting digital projects. We have purposely kept the program small; working with a cohort of four to six graduate student "partners" each summer. Our strategy was, no doubt, also influenced by discussions of sustainability in the Digital Humanities community (see, for example, Maron and Pickle, 2014). What if we built a new program as though we were already in the sunset period? How could we minimize costs, maximize impact, build deep connections with researchers, respect ethical issues of graduate student labor, and facilitate engagement between library staff and researchers? We knew about minimal computing, but could we create a "minimal program" and still have an impact?

The goal of the program is to provide graduate students with skills and methods to continue the projects on their own. Rather than doing projects for them, we focus instead on teaching students to start with a small sample of their own dataset, working it through the research data lifecycle: collecting, cleaning, and analyzing/visualizing data, supplemented by a workshop on project management and the specific tools that are applicable to the students' research projects. In the second half of the program, we focus on the execution of their individual projects, building prototypes and adjusting workflows that allow them to complete their projects independently.

After successfully offering this program for the past two years, we are expanding the program in ways that we hope will increase the library's capacity to support digital scholarship, which will make the program more sustainable over time and allow us to reach more researchers. Perhaps because we took a low-profile, grassroots approach, and because of general resistance to "reskilling" or "retooling" efforts, the most surprising response to DResSUP for us has been the enthusiasm and curiosity of our library colleagues. As they have learned more about the program, they have expressed interest in participating. However, at the same time, they raised legitimate concerns about their ability to support advanced digital research methods. Recognizing that they face a steep learning curve, one that will require additional resources to surmount, we have designed an expansion to the program, developing a second track for professional development for librarians.

Similar to Columbia University Library's Developing Librarian and Indiana's Research Now librarian training programs, we will take a project-based approach to professional development for librarians. But, rather than developing a separate program, librarians will participate in the extended DResSUP program, starting earlier in the year, gradually merging with the summer DResSUP graduate students. We will begin working with a small cohort of librarians in January 2017, who will follow the same curriculum as the graduate students. By Summer, the librarian cohort will have a plan for a collaborative digital research project.

Our short paper will begin by presenting DResSUP as it has functioned the past two years and our plans for the next three years, based on preliminary findings from this second librarian track of DResSUP which, by DH2017, will be well underway. We reason that by building capacity in our library community among permanent staff we can extend and grow DResSUP in ways that are beneficial to both researchers and those responsible for building and maintaining the infrastructure that supports those endeavors. We will then discuss results from an open-ended questionnaire that we have designed to surface some of the issues around collaboration between librarians and digital humanities researchers (Siemens et al, 2011) and provide concrete suggestions for faculty, library administrators, and library staff members. Typically, the library's role in a digital project is negotiated when faculty are writing grant proposals and seek assistance with a required data management plan. We will argue that this strategy puts librarians at a disadvantage, having to function as gatekeepers in a bargaining process when researchers are hard pressed to stretch precious resources between their research goals and an institution's needs to cover the costs of supporting research functions.

Finally, we will discuss the ways in which merging professional development for librarians with graduate students provides advantages by focusing library engagement efforts at an earlier stage, i.e., when graduate students begin research for their dissertations or when they begin working as research assistants. We will argue that graduate students function as vectors for spreading the message that librarians can provide valuable expertise: they teach undergraduate students, their peers, and their faculty. In this way, librarians can expand their impact, by focusing strategically on graduate students.

I Built an App to Revitalize a Language: Now What?

Nicolle Bourget
nbourget299@telus.net
Royal Roads University, Canada

Summary

Indigenous communities are using technology to document languages and support language maintenance and revitalization activities. My research examined how technology has been incorporated into Upriver Halq’eméylem language programs. Participants identified that ICT is being used successfully as a supplementary tool in coordination with specific learning strategies and activities such as story-telling, games, and looking up a word or concept but that the ICT is not being used outside of those specific learning activities. The study indicates that ICT can be a valuable tool in the effort to revitalize a language; however, technology to revitalize languages needs to be carefully planned with post-implementation activities and oversight to ensure that the language continues to grow.

A Real-World Problem

Linguists estimate that 50-90 percent of the 6,000 to 7,000 known languages in the world will disappear in the 21st century (Grenoble, 2011) with Harrison (2007) estimating that loss is occurring at a rate of one language every ten days. Endangered languages are often spoken primarily, or only, by Elders and as fluent Elders are lost, so is the language. Indigenous languages in Canada are not exempt from language shift; indeed, only 50 of the more than 60 Indigenous languages known to have been spoken in Canada exist today and most of these languages are classified as either endangered or already extinct (Kirkness, 1998). Only three (Norris, 1998) or four (Kirkness, 1998) of these languages are expected to survive.

The loss of an Indigenous language is associated with the loss of Indigenous knowledge and culture. Such knowledge systems incorporate social and historical dimensions including social relationships, cosmology or world views, oral history, place names, spiritual relationships, ecological knowledge, oral literatures, and philosophies (Battiste, 2008; Berkes, 1993; Hinton, 2008a, 2008b; Kipp, 2009). These knowledge systems are embedded within the language and the loss of the language results in the loss of the knowledge systems. Language is important to the health of the community and language revitalization has been identified as playing “a vital role in community growth, healing, education, development, strong families and reconnection to the past” (First Peoples’ Heritage, Language and Culture Council, 2010: 7). Language loss and revitalization is a global, real world problem.

Challenges

Challenges to language revitalization include lack of ideological clarification (Dauenhauer and Dauenhauer, 1998); disagreement as to recording or sharing language (Adley-SantaMaria, 1997); differences in personal beliefs (Kroskrity, 2009); economic impacts (Adegbija, 2008; Hornberger and King, 2008; Kroskrity, 2009); the perceived status of a language and the self-esteem of speakers; and feeling shame and embarrassment about the language and culture (Dauenhauer and Dauenhauer, 1998).

The digital divide is another potential barrier to language revitalization. The digital divide separates individuals and communities who have access to technology and those individuals and communities that do not. Exacerbating the issue of the digital divide is that language programs may inadvertently become technology projects which “often focus on providing hardware and software and pay insufficient attention to the human and social systems that must also change for technology to make a difference” (Warschauer, 2004: 6). Discussions around the digital divide must include the technical aspects such as access to technology and problems with infrastructure as well as the social aspects including education in the technology, gender, age, language, economics, and literacy (Warschauer, 2004).

Technology

Information and communication technology has been used with languages since the late 1800s, when audio recordings of Indigenous peoples were made on wax cylinders (Makagon and Neumann, 2008). These recordings allowed for unidirectional activity; that is, individuals could listen to the recording but could not interact with it. Today, the advances in ICT can provide an interactive, bi-directional experience in which users can interact either with the technology or other users. Language can also be captured in context with cultural activities allowing for a deeper understanding of the language. Multimedia applications are becoming increasingly easy to create and allow for the integration of video, audio, pictures, and text, as well as interaction with human beings. Access to databases and dictionaries provides teachers, administrators, and learners immediate access to language at the word, grammatical, and contextual levels. However, Tyler (2002) notes that:

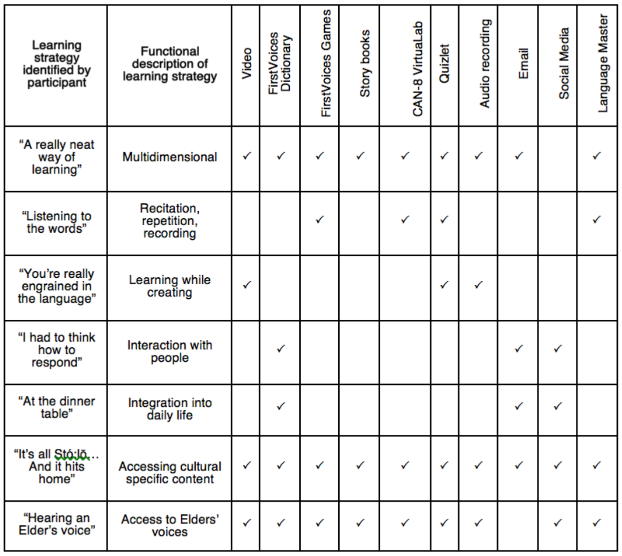
> *"The Internet provides people with a technology that allows them to engage in activities that they have already had ways to engage in but provides them with some added efficiencies and opportunities to tailor their interactions to better meet their needs. However, there is nothing fundamentally different about the Internet that transforms basic psychological or social life.* " (204)

If we apply this statement to Indigenous language programs, technology will be most successful where the language is already being used and where the language is not being used, technology will not increase the usage as is the case of the Upriver Halq'eméylem language community. An endangered language requires very different strategies than a thriving language, and these strategies should determine how digital technologies are used. For example, a community with a thriving language may use technology to encourage conversations between geographically dispersed individuals, to increase the use of language through written communication using email or chat functions, or to provide exposure to the language by posting information on social media sites or blogs. A community with an endangered language may choose to use technology for documentation and archiving so that the language is not lost forever.

My research attempted to understand the effectiveness of technology within an established language program with the goal of providing additional information to help communities that are either considering a language program or have one in flight that uses technology.

Findings

The Upriver Halq'eméylem language community began to use ICT in the mid-1900s to document their language. Over time, the community continued to incorporate ICT and today ICT is an integral tool in the teaching of the language. Table 1 identifies the ten technologies identified as being used with the Halq'eméylem language along the top row and the learning strategies used in the first column.



Learning strategy identified by participant	Functional description of learning strategy	Video	FirstVoices Dictionary	FirstVoices Games	Story books	CAN-8 VirtualLab	Quizlet	Audio recording	Email	Social Media	Language Master
"A really neat way of learning"	Multidimensional	✓	✓	✓	✓	✓	✓	✓	✓		✓
"Listening to the words"	Recitation, repetition, recording			✓		✓	✓				✓
"You're really engrained in the language"	Learning while creating	✓					✓	✓			
"I had to think how to respond"	Interaction with people		✓						✓	✓	
"At the dinner table"	Integration into daily life		✓						✓	✓	
"It's all Stó:lō... And it hits home"	Accessing cultural specific content	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓
"Hearing an Elder's voice"	Access to Elders' voices	✓	✓	✓	✓	✓	✓	✓		✓	✓

Table 1: Intersection between ICT and learning strategies as identified by participants

Understanding the how the learning strategies intersected with the technology used provided key information as to how the technology supports language learning. Participants identified that ICT is being used successfully as a supplementary tool in coordination with specific learning strategies and activities such as story-telling, games, and looking up a word or concept but that ICT is not being used to support Halq'eméylem learning activities outside of those specific learning activities. Additionally, participants indicated that ICT that enables human to human interaction has significant potential to contribute to developing fluency but only if the language is already being used.

Table 1 highlights that ICT is rarely used with the Halq'eméylem language outside of learning situations such as classrooms. This does not seem to be related to any digital divide issues as participants confirmed that they and other community members use ICT on a regular basis for non-language related activities. There may be multiple reasons why participants do not use ICT with the Halq'eméylem language; however, Burton suggested that the primary reason that Halq'eméylem specific ICT is not used by community members is because people do not use the language:

> *"But the thing about the technology, the thing about everything, classes, education, language planning, everything that we try to do, it's like we're trying to support something that's not happening. So, if people were talking to their aunt and their grandmother or a couple that said we're going to make Halq'eméylem a part of our life and so on, then the technology and the classes could help them. But if all you have is the technology, then that's not going to solve the problem. The problem is a social problem, or a personal problem."* (personal communication, July 11, 2013)

Technology will be most successful where the language is already being used and, where the language is not being used, technology will not increase the usage as in the case of the Upriver Halq'eméylem language community. Technology to revitalize languages needs to be carefully planned with corresponding plans to introduce the technology and then post-implementation activities and oversight to ensure that the language continues to grow.

Makers by Mail: Providing Makers Technologies to All

Christina Boyles-Petersen
christina-boyles@uiowa.edu
University of Iowa, United States of America

Lindsay Kistler Mattock
lindsay-mattock@uiowa.edu
University of Iowa, United States of America

Andrew Boyles-Peterson
andrew-petersen@uiowa.edu
University of Iowa, United States of America

This paper explores the development of Makers by Mail, a model for a mobile makerspace targeting graduate and undergraduate Digital Humanities scholars. While makerspaces (fablabs, hackerspaces, creative spaces) have steadily developed in libraries, university campuses, and community spaces over the past few years, these centers of innovation are often rooted in a particular place. Even mobile makerspaces, like the DHMakerBus, reach a limited audience by requiring users to gather in a particular place at a specific time. In response, we propose a new model for mobile makerspaces that emphasizes prototyping as pedagogy. This method involves shipping small, physical computing technologies and instructions to users using flat-rate priority mail boxes. Designed to support experiential learning - learning through making - the makerspace focuses on the computer processes that go into making rather than the products produced by them. As such, it emphasizes the process of making itself, whether successful, failed, or flawed.

Using an online checkout system, these kits are available for the cost of shipping (and the replacement cost of any lost or damaged parts). Training is provided through print materials as well as through the teaching commons on the Makers by Mail website. The mobility and affordability of these kits creates a new user experience for those involved by making digital tools accessible to individuals in traditionally unreached groups—rural and socioeconomically challenged communities. This model, therefore, gives a diverse group of users the opportunity to access advanced digital tools and, in the process, engages participants in critical making and maker culture, allowing them to gain confidence in coding, building, and digital literacy.

In *Debates in the Digital Humanities* Alexander Reid suggest that most graduate students have had little exposure to digital technology during their undergraduate education, “enter[ing] his or her graduate education as a novice in regards to the digital" (357). His assessment applies to our broader community of Eastern Iowa. Our initial findings suggest that many of the students approach technology with anxiety due to their lack of experience with computer programming. To address our users’ lack of technological expertise, we are scaffolding projects using a variety of technologies, including: littleBits, Raspberry Pi, and Arduino boards. These tools were selected for their mobility, accessibility, and affordability. Each of these factors allows for implementation of the makerspace in unconventional venues—secondary schools, adult education classes, and community events. Additionally, projects developed for each of these tools can be scaffolded, gradually increasing participants’ comfort and literacy with digital toolsand technologies.

This paper will report on the first phase of development of the Makers by Mail project. Over the first year of development, Makers by Mail kits were used in a variety of settings, from public makerspace events, to conference workshops, and in classrooms across the University of Iowa. In this second year, we are pursuing partnerships with community partners outside of Iowa City and beyond the borders of the state, including the University of Kansas, Grinnell

College, and the Williamsburg Public Library. For this paper, we will focus on the use of the kits as part of coursework for students in the University of Iowa School of Library and Information Science and humanities students enrolled in the Public Digital Humanities Certificate. These three case studies will illustrate the pedagogical potential of the kits and demonstrate three different modes of engagement with the technology.

Case 1: Teaching Digital Literacy with Raspberry Pi

All students enrolled in the Library and Information Science MA program must complete Computing Foundations in their first term of study. This course is designed as an introduction to many of the technologies that the students will encounter and engage with during their course of study at SLIS. The course provides a broad introduction to many technologies that Digital Humanities scholars utilize as well: XML, HTML, Python, and LAMP server-based platforms. For this audience we utilized a flipped classroom, using Raspberry Pi computer kits for a series of guided projects. By the end of the term, students had a working LAMP server with self-hosted websites and had engaged with encoding documents in XML, transformed XML into HTML with XLST, and interrogated those documents using Python scripts. This kit was designed not only to familiarize students with the technologies they are likely to encounter in practice, but to build key digital competencies in coding and working at the command line - skills necessary for engaging with Digital Humanities methodologies as well.

Case 2: Digital Humanities Project Development with Arduino

The second case reports on the use of Arduino kits for students enrolled in the university’s Introduction to Digital Humanities seminar. This course is designed to introduce students to digital humanities methodology and requires that they propose, research, develop, and launch a digital project. In this class, students use Arduino kits to create a data visualization of their research projects. Although initially skeptical, students demonstrated excitement once they had the opportunity to experiment and play with the technologies. By the end of the term, they developed creative and functional Arduino projects on topics including book censorship, digital art, and Walt Whitman. In doing so, they acquired both literacy with physical computing technologies and new understandings of data visualization.

Case 3: Designing Makers by Mail Kits

Our final case illustrates the philosophy of Makers by Mail and offers insight into the design and development of our kits. As part of the Digital Environments course (an elective course for DH Certificate students), students were asked to work with humanities faculty from the University of Iowa and other community partners to develop kits for targeted audiences. Over the first few weeks students were introduced to the concepts of critical digital pedagogy, design thinking, and values in design. They were then asked to apply theory to their practice by prototyping and developing kits and lesson plans to be implemented in specific classrooms and included on the Makers by Mail website. These kits included two Digital Shakespeare kits, a sound surveillance kit to pair with Hamlet, as well as a scene mapping kit using Arduino boards.

Methodology

In each of these cases, we assessed the increased digital literacy, competency, and confidence of the students through a series of surveys, journaling exercises, and participant observation. At the beginning and end of the term, each student completed a survey that asked students to rate their experience and comfort level with a variety of technologies (from computers, to cell phones, makers tech, and wearables), along with a series of open-ended questions gauging expectations and general feelings about technology. In Computing Foundations, students were also given a pre- and post-questionnaire designed to test and gauge the students' digital literacy.

Throughout the term, students were asked to keep a process log and reflective journal; this metacognitive strategy provided an opportunity for students to reflect on their thinking and learning process and produced multiple data points to track student progress throughout the semester. Finally, all students were required to submit one final reflection at the end of term, summarizing their experience and the major takeaways from the course.

Conclusions

Regardless of the student's indicated level of experience at the beginning of the term, all students reported an increase in their comfort and ability to engage with digital technology, from physical computing technologies like the Arduino to more traditional technologies like the Raspberry Pi computers. We argue that the self-contained nature of the kits and the pedagogy built into the technologies afforded students opportunities to play, tinker, and experiment, and that this trial-and-error experimentation and prototyping allowed students to critically engage with digital technologies in a way that the black-boxed, pre-packaged devices that students typically engage with do not. Further, the mobility of the kits offered opportunities for students to gain a sense of ownership of the technologies, transporting the kits from the classroom to their personal spaces and working without the constraints of a place-bound makerspace.

The use of the kits not only affords opportunities for makers to build confidence creating and experimenting with digital tools but also provides students with opportunities to critically engage with technology and build digital literacy skills that address other key aspects of DH education, including: working in interdisciplinary teams, applying digital practices, managing projects, and explaining technology (Rockwell and Sinclair 182-183). Ultimately, we argue that this model can be emulated in other educational settings as a new model for DH pedagogy that is more accessible and more collaborative than traditional makerspaces.

Scaffolded Hermeneutica for Literary Scholars with Novice Technical Skills

Jeremy Browne
jeremy_browne@byu.edu
Brigham Young University, United States of America

Hermeneutica

In *Hermeneutica*, Geoffrey Rockwell and Stéfan Sinclair (2016) argue for an approach to the digital humanities that deemphasizes the tool and positivist notions of proof. Their proposed approach, also called **Hermeneutica**, champions tool accessibility over tool sophistication. Similarly, scholarly play is legitimated as a useful step in developing research questions and as a means to reconsider established notions within literary disciplines. The aim of Hermeneutica as a methodology seems to be the generation of interesting humanistic questions as much as the resolution of open questions.

Rockwell and Sinclair demonstrate the difference between Hermeneutica and typical DH approaches by quoting from Gary Wong's 2009 blog post:

> [Typical DH] takes the worst part of the scientific papers (really really long sets of tabular data in the body of the text) and the worst part of papers from the humanities (really really complicated language where simple language would have done) and puts it in one. If this is what the cooperation of computational text analysis and traditional literary analysis yield, I am scared.

Because Hermeneutica attempts to join the **best parts** of these fields, it has the potential to turn DH into a discipline that is more useful for the vast majority of non-DH humanists. It could be the means of accelerating the mainstreaming of DH methods and bringing us to the eventual point where all humanities are digital—a destination Claire Clivaz described succinctly (DARIAH, 2016).

Voyant

One feature that distinguishes Hermeneutica from many other DH approaches is its companion set of tools meant to demonstrate its application. Voyant Tools, now referred to simply as Voyant, is a web-based, modular suite of tools meant to be "worth thinking **with**" (Rockwell and Sinclair, 2016: 10, original emphasis). The goal is to accommodate playful exploration of text and sharing of corpora across the web. It is not designed as an industrial-grade text analysis tool, but as a "toy" that allows scholars to uncover new questions and gain new appreciation of texts.

Current limitations of Hermeneutica

A fundamental component of Hermeneutica is that the scholar views text through the lens of Voyant (or other computational text analysis tools), and then synthesizes that experience with their prior knowledge of the text and its milieu. A problem that Voyant addresses, but does not solve, is that many scholars who know the most about specific texts lack the technological skills that would be considered pre-novice in DH circles. Voyant allows everyone with a text and a browser to explore word frequencies, collocations, etc., but it presupposes that the text is available and clean enough for use. In order for Hermeneutica to appeal to non-DH humanities scholars, these issues of text availability and the lack of user skill must first be addressed.

On the issue of text availability, it is not often that scholars wish to analyze text that is rare or missing. More often they are interested in text that is protected by various copyright laws, which prohibit posting the text to public websites such as Voyant. Thankfully, in the Unites States at least, Google Books' recent court victory (Stohr, 2016) now permits scholars to publish online the analysis results derived from copyrighted texts, so long as the original text is not recoverable by the user. To this end Rockwell and Sinclair developed Voyant 2's "non-consumptive" mode which restricts access to tools that allow full-text views.

While such developments represent Rockwell and Sinclair's amenability to meet the ever-evolving needs of Hermeneuticans, accommodating users' lack of technology skill is beyond the scope of their involvement. For example, it is not reasonable to expect the Voyant developers to be concerned over issues of text acquisition or text preparation. Rather, those concerns—while critical to expanding the pool of potential Hermeneuticans—are issues of local implementation. Similarly, it makes sense that Voyant would offer the ability to link to a corpus after uploading the text, but uploading the text and keeping track of various versions of corpora is beyond the scope of Voyant. A local practice of adding some structure around the Voyant suite ought to make Hermeneutica useful to a far greater audience than it is now.

Scaffolding

In the field of instructional design, such structure is called **scaffolding**. Specifically, scaffolding refers to the process of providing learners adequate introduction and examples before allowing them to attempt a task on their own (Bruner, 1978). For **scaffolded Hermeneutica**, DH-savvy professionals can work to acquire, clean, and upload text to Voyant (and other tools), and then provide public listings of the resulting corpora.

Examples of scaffolded Hermeneutica

We have implemented this scaffolded Hermeneutica approach in our Office of Digital Humanities beginning with the Cormac McCarthy Corpus Project (CMCP). The CMCP includes 13 Voyant corpora of McCarthy's 10 novels: one for the complete works, one for each novel, and two for novels (*The Orchard Keeper* and *The Road*) where the narration has been segregated from the dialogue. But the linchpin of scaffolded Hermeneutica is the CMCP's publicly-accessible website that organizes these Voyant corpora. The website is built on WordPress with the Pods content management plugin, and contains information on McCarthy's work, descriptions of Voyant (and other tools), and listings of links to the Voyant corpora. An essential feature of the website's structure is the ability to accommodate revisions to the current corpora as well as the addition of other tools in the future. Already, there is a non-Voyant sentence structure search tool attached as a beta-testing option.

A rough version of the Cormac McCarthy Corpus Project was presented at the 2015 conference of the Cormac McCarthy Society. The reaction to these tools being available for public use was strongly positive. One attendee referred to the website as "a game-changer."

The same scaffolded Hermeneutica is being implemented on two other projects: *Machado à longa distanciâ* and The Modernist Short Fiction Project. Preliminary demonstrations of the approach have yielded similar reactions to what we observed with the CMCP. Non-DH scholars become excited rather than anxious when the digital analysis tools are scaffolded to provide them ready access. In fact, these demonstrations turn into play sessions where non-DH scholars repeatedly request for certain words to be added to the frequency charts and other Voyant panels.

Conclusion

Hermeneutica and Voyant represent the greatest potential for growth in DH not because they are the most technologically or theoretically **advanced** developments, but because they are the most **accessible** to non-DH scholars. Still, they don't quite reach the ground level of technology skills possessed by most researchers in the humanities. The scaffolded Hermeneutica approach proposed in this paper seems to span that gap to make Hermeneutica more accessible.

Puns and Intertextuality: A Digital Approach to Greek Wordplay in Latin Literature

Background

As one of the defining features of Latin literature, the influence exerted by the Greek linguistic and textual traditions has remained a key focus of the Classics. One of the manifestations of this intersection of cultures is in the topic of wordplay, or puns. Authors such as Vergil and Lucretius have been shown to utilize the metrical rules of pronunciation to embed Greek word forms in their poetry, and in the process, reference others works of literature and convey ideas beyond the superficial level of the text. While the influence of Greek writings upon Latin literature has received considerable scrutiny, the use of Greek puns has received only limited inquiry. Previous studies on puns, notably those of Snyder (1980) and Ahl (1985) are limited in scope and focus mainly on the relationship of Latin puns to Latin literature. Furthermore, studies which focus on Greek puns within Latin are limited primarily to writing about specific examples or a specific Latin author, such as O'Hara (1996) and his discussion of Greek word use in Vergil. Similarly, the recent (2013) compilation of studies edited by Kwapisz, Szymanski, and Petrain examining Greek and Latin wordplay does not look at the intersection of the two. Building upon previous strategies for data mining including the Tesserae Project, this paper seeks to offer a digital means to cross-reference Latin literature with Greek texts in order to find puns.

The program

Since the formation of our collaboration, we have produced software capable of detecting potential candidates for Greek puns. To achieve this end, we first set out to account for the rules of pronunciation within Latin poetry by referencing works such as Halporn et al. (1980), with issues such as elision and the lack of pronunciation of certain syllables addressed within the software. We then looked to set equivalence of pronunciation between Greek and Latin letters and groups of syllables, such as diphthongs. This was accomplished through examining transliterated Greek names and words which appear in Latin literature and using grammars including Smyth (1920). Additionally, certain Greek vowels and consonants which could correspond to multiple vowels, consonants, or syllables in Latin were also considered.

Accounting for these rules, we developed a processing system whereby Greek pronunciation equivalence is run through strands of Latin text. The software begins by reading one chosen Latin text in .txt format and then reading one or more Greek texts in .txt format, with all texts requiring UNICODE encoding for proper registration within the identification system. Once a Latin and Greek text(s) have been selected, the file paths are passed asynchronously into the model for processing. Both texts are then processed at the same time on different threads and the calling method waits for the completion of both methods.
