18 **Abstract**

19

20 Formaldehyde is a carcinogenic substance for humans. Exposure to formaldehyde may  
21 also cause eye and respiratory tract irritation, as well as skin sensitization. The main  
22 indoor sources of formaldehyde are wood-pressed products, insulation materials, paints,  
23 varnishes, household cleaning products and cigarettes, among others. Although this  
24 chemical is a well-known indoor pollutant, data on indoor concentrations of  
25 formaldehyde are still scarce in some countries. In February 2014, 10 homes in  
26 Catalonia, Spain, were randomly selected to collect indoor (bedroom and living room)  
27 and outdoor air samples. Ten additional samples were also collected at different  
28 workplaces (e.g., offices, shops, classrooms, etc.). Formaldehyde air levels found in  
29 homes ranged from 10.7 to 47.7  $\mu\text{g}/\text{m}^3$ , from 9.65 to 37.2  $\mu\text{g}/\text{m}^3$ , and from 0.96 to 3.37  
30  $\mu\text{g}/\text{m}^3$  in bedroom, living room, and outdoors, respectively. Meanwhile, at workplaces  
31 indoor air levels ranged from 5.86 to 40.4  $\mu\text{g}/\text{m}^3$ . These levels are in agreement with  
32 data found in the scientific literature. Non-carcinogenic risks were above the threshold  
33 limit ( $\text{HQ}>1$ ), and carcinogenic risks were not acceptable as well ( $>10^{-4}$ ). Despite the  
34 current study limitations, the results confirm that formaldehyde indoor levels are a  
35 matter of health concern, which must be taken into account by policy makers and  
36 regulatory bodies.

39 risks

40

41 **Introduction**

42

43 Formaldehyde is a natural compound formed in vegetal residues decomposition and  
44 combustion processes. It is also a normal component of blood, being essential in human  
45 metabolism for the biosynthesis of purines, thymidine, and some amino acids. <sup>[1-4]</sup> At  
46 room temperature, formaldehyde is a colorless gas with an acrid and irritating odor,  
47 highly reactive and flammable. Due to its properties and reactivity, formaldehyde is  
48 used as precursor for more complex compounds. <sup>[5]</sup> Urea-formaldehyde resins,  
49 representing about 46% of formaldehyde world consumption, are used as adhesive in  
50 particle board and plywood production and color preservative in clothes. The other  
51 formaldehyde-derived resins are used for products applications in automobile  
52 components, fiber glass insulation, laminates, and surface coatings. <sup>[6]</sup> Finally, other  
53 applications for formaldehyde derived products compounds are paints, varnishes,  
54 textiles, fungicide, fertilizers, preservers, and cosmetics, among others. <sup>[7-11]</sup>  
55 Formaldehyde does not accumulate in the environment due to its low half-life.  
56 However, it is continuously released or formed, leading to a long-term exposure for  
57 populations living near emission sources or production activities. <sup>[12]</sup> Furthermore,  
58 formaldehyde can also be formed in a reaction of ozone with unsaturated volatile  
59 organic compounds (VOCs). <sup>[13,14]</sup>  
60 Despite its widespread use, formaldehyde is classified as a carcinogen (Group 1) by the  
61 International Agency for Research on Cancer (IARC), and as a known human  
62 carcinogen by the US National Toxicology Program. <sup>[3,4]</sup> Formaldehyde causes cancer  
63 of the nasopharynx and leukaemia and a positive correlation between formaldehyde  
64 exposure and sinonasal cancer has been showed. <sup>[4]</sup> Short-term exposure symptoms  
65 include eyes and respiratory airways irritation, with a concentration-dependent increase  
66 of tearing, sneezing, coughing, nausea, dyspnoea and finally death. <sup>[15]</sup> Long-term

67 exposure to elevated formaldehyde levels results in airway and eye irritation, as well as  
68 in degenerative, inflammatory and hyperplastic changes of the nasal mucosa. <sup>[15]</sup>  
69 Formaldehyde can be found in the air of most, if not all, homes and buildings. <sup>[1,4,</sup>  
70 <sup>7,8,11,16-20]</sup> However, there is a lack of data in the scientific literature regarding  
71 formaldehyde and other (e.g., xylene, toluene, benzene) indoor pollutant levels in a  
72 number of countries, including Spain. <sup>[18]</sup> For that reason, the present study was aimed  
73 at determining air formaldehyde levels in homes and workplaces in Catalonia, Spain, as  
74 well as assessing the associated human health risks.

75

## 76 **Materials and methods**

77

### 78 *Sampling*

79

80 In January/February 2014, forty air samples were collected in Tarragona County,  
81 Catalonia, Spain. Ten homes were randomly selected and three samples, one in  
82 bedroom, one in living room and another one outside the building (terrace or balcony)  
83 were collected in each house. Ten more samples were collected at different workplaces  
84 including kindergarten, shops, classrooms, and offices. The researchers requested to the  
85 residents (homes) and workers (workplaces) to continue with their normal activities  
86 during the sampling. Details about sampling points are given in Table 1.

87 An Airchek 2000 sampling pump (SKC Inc., Eighty Four, PA, USA) was used for air  
88 collection. Samples were collected by passing air through sorbent tubes containing 2,4-  
89 dinitrophenylhydrazine-coated silica gel. Flow rates were set at 1 L/min, with a  
90 sampling duration of 8 h. Total air volumes were approximately 480 L. After collection,  
91 samples were frozen and kept at  $-20^{\circ}\text{C}$  until analysis. The temperature during the

92 sampling ranged between 19 and 23°C, and between 9 and 17°C, in indoor and outdoor  
93 environments, respectively. The indoor and outdoor ranges of relative humidity were  
94 32-58% and 32-63%, respectively.

95

#### 96 *Analytical method*

97

98 Formaldehyde was desorbed from tubes with 2 mL of acetonitrile in an ultrasonic bath  
99 for 30 min. The analysis was performed by high pressure liquid chromatography with  
100 ultraviolet detection (HPLC-UV), using a C-18 column. <sup>[21]</sup> The initial mobile phase  
101 was acetonitrile:water (50:50). The gradient program for acetonitrile, given as time-  
102 concentration percentage, was the following: min. 0.1 – 50%, min. 5 – 50%, min. 20 –  
103 80%, min. 25 – 100%, min. 48 – 50%, min. 52 – stop. Calibration was done by using  
104 standard solutions of DNPH derivatives of aliphatic aldehydes in acetonitrile. Blank and  
105 replicates were analysed every batch of samples for QC/QA. The detection limit was 0.2  
106 µg/m<sup>3</sup>.

107

#### 108 *Human health risk assessment*

109

110 The formaldehyde concentrations were used to assess the inhalation risk for human  
111 health through inhalation. The numeric expressions were taken from the United States  
112 Environmental Protection Agency (US EPA) RAGS methodology. <sup>[22]</sup> Inhalation  
113 exposure levels ( $Exp_{inh}$ ) (in µg/(kg·day)) were calculated according to the equation 1.

114

$$115 \quad Exp_{inh} = \frac{\sum_i (C_i \times IR_i \times F_i) \times EF}{BW \times 365} \quad (1)$$

116

117 where  $C_i$  was the concentration of formaldehyde in air (in  $\mu\text{g}/\text{m}^3$ ) in each location,  $IR_i$   
118 was the inhalation rate (in  $\text{m}^3/\text{day}$ ),  $F_i$  was the day time fraction spent (unitless),  $EF$  was  
119 the exposure frequency (in day/year),  $BW$  was the body weight (in kg), and 365 was a  
120 conversion unit factor (in day/year).

121 After exposure evaluation, the associated non-carcinogenic and carcinogenic risks were  
122 assessed. Inhalation risks were calculated based on the inhalation dosimetry  
123 methodology. <sup>[20]</sup> In contrast with the old intake methodology, in which inhalation rate  
124 and body weight were key parameters, the new method suggests that the amount of  
125 chemical reaching the target site through inhalation, is directly related to the exposure  
126 concentration (EC), being not a simple function of inhalation rate and body weight. <sup>[20]</sup>

127 Exposure concentrations (EC) were used for the assessment of non-carcinogenic and  
128 carcinogenic risk, meanwhile  $Exp_{inh}$  informs regarding exposure levels of the population  
129 to formaldehyde. Once the EC was assessed, the characterization of non-carcinogenic  
130 risks consisted of the calculation of the Hazard Quotient (HQ), which is defined as the  
131 relation between the predicted exposure concentration and the inhalation reference dose  
132 ( $RfD_{inh}$ ). Cancer risks were assessed by multiplying the predicted exposure  
133 concentration by the inhalation unit risk (IUR). The  $RfD_{inh}$  and the IUR were obtained  
134 from the risk assessment information system. <sup>[23]</sup> The equations to determine the risks  
135 were the following (equations 2 to 4):

136

$$137 \quad EC = \frac{\sum_i (C_i \times F_i) \times EF \times ED}{AT \times 365} \quad (2)$$

138

$$139 \quad HQ = \frac{EC}{RfD_{inh}} \quad (3)$$

140

141  $Cancer\ risk = EC \times IUR$  (4)

142

143 where  $C_i$  was the concentration of formaldehyde in air (in  $\mu\text{g}/\text{m}^3$ ) in each location,  $F_i$   
144 was the day time fraction spent (unitless), EF was the exposure frequency (day/y), ED  
145 was the exposure duration (in years), AT was the averaging time (in years), BW was the  
146 body weight (in kg), 365 was a conversion unit factor (in day/y),  $RfD_{inh}$  was the  
147 inhalation reference dose of formaldehyde (in  $\mu\text{g}/\text{m}^3$ ), and IUR was the inhalation unit  
148 risk (in  $\text{m}^3/\mu\text{g}$ ).

149 The uncertainties associated to the human exposure and health risks were also assessed  
150 by means of Monte-Carlo simulations, which were done by applying the Crystal Ball  
151 4.0 software (Decisioneering, Inc.), and considering 100,000 iterations. Each modelling  
152 parameter was expressed as a probability distribution function so that a probabilistic  
153 distribution was obtained as a result. Detailed information of the probabilistic  
154 parameters is shown in Table 2.

155

### 156 *Statistics*

157

158 Data analysis was carried out by means of the statistical software package SPSS 20.0.  
159 The level of significance was set at a probability level lower than 0.05 ( $p < 0.05$ ). To  
160 evaluate significant differences between formaldehyde levels groups in the different  
161 locations, the Levene test was applied to verify the equality of variances. ANOVA or  
162 Kruskal Wallis tests were subsequently applied depending on whether the data followed  
163 a normal distribution or not, respectively.

164

165 **Results and discussion**

166

167 *Formaldehyde levels*

168

169 The concentrations of formaldehyde in sampled air are depicted in Figure 1, with the  
170 correspondent median, maximum, and minimum values, as well as the 25<sup>th</sup> and 75<sup>th</sup>  
171 percentiles. Formaldehyde mean levels in samples of indoor air were 27.3  $\mu\text{g}/\text{m}^3$  (range  
172 from 10.7 to 47.7  $\mu\text{g}/\text{m}^3$ ) and 22.5  $\mu\text{g}/\text{m}^3$  (range from 9.6 to 37.2  $\mu\text{g}/\text{m}^3$ ) in bedrooms  
173 and living rooms, respectively. Similar levels were found in indoor air at workplaces,  
174 with a mean concentration of 21.8  $\mu\text{g}/\text{m}^3$ , ranging from 5.9 to 40.4  $\mu\text{g}/\text{m}^3$ . Outdoor level  
175 in houses (terrace or balcony) was significantly ( $p < 0.05$ ) lower than indoor levels, being  
176 the average outdoors 1.6  $\mu\text{g}/\text{m}^3$  (range: 1.0-3.4  $\mu\text{g}/\text{m}^3$ ). No significant differences  
177 ( $p < 0.05$ ) were obtained between indoor formaldehyde levels (bedroom, living room and  
178 workplaces). A positive significant correlation of indoor formaldehyde concentrations  
179 ( $p < 0.01$ ) was found between bedrooms and living rooms (Pearson's correlation  
180 coefficient: 0.855). This could be due to the common sources of emission or/and  
181 diffusion of formaldehyde indoor levels through house rooms. No correlation between  
182 formaldehyde indoor and outdoor levels was found. Generally, outdoor formaldehyde  
183 does not contribute to indoor pollution (or the contribution is minor) since ambient  
184 levels are usually rather low. [24]

185 Indoor and outdoor formaldehyde levels are consistent with those reported in other  
186 countries. In a recent review, Sarigiannis et al. [18] found that typical indoor  
187 concentrations ranged from 10 to 50  $\mu\text{g}/\text{m}^3$ , being 46 and 37  $\mu\text{g}/\text{m}^3$  in bedrooms and  
188 living rooms, respectively. In the same review, Sarigiannis et al. [18] also pointed out  
189 that indoor formaldehyde levels in residential buildings of North and Central European

190 countries were higher ( $29.8 \mu\text{g}/\text{m}^3$  (range from  $4.8$  to  $115 \mu\text{g}/\text{m}^3$ )) than in Southern  
191 European countries ( $12.7 \mu\text{g}/\text{m}^3$  (range from  $5.2$  to  $32.9 \mu\text{g}/\text{m}^3$ )). In turn, Nielsen et al.  
192 <sup>[19]</sup> reported that usual indoor levels in US and Europe homes are within  $20$ - $40 \mu\text{g}/\text{m}^3$ ,  
193 while ranges of outdoor levels are between  $1$  and  $4 \mu\text{g}/\text{m}^3$ . According to Salthammer  
194 <sup>[11]</sup>, formaldehyde concentrations in urban areas may usually reach  $40$  ppb ( $49.2 \mu\text{g}/\text{m}^3$ )  
195 and  $15$  ppb ( $18.5 \mu\text{g}/\text{m}^3$ ) in indoor and outdoor environments, respectively. However,  
196 these “normal” concentrations should not be considered as safe.

197 Recent data, not included in the abovementioned reviews, are summarized in Table 3.  
198 Excepting some point cases, such as remodelled dwellings in China, or mobile homes in  
199 USA, the results (Table 3) are in agreement with the levels found in the current study.  
200 In Spain, Alves et al. <sup>[25]</sup> found concentrations around  $4$ - $6 \mu\text{g}/\text{m}^3$  in two sport facilities,  
201 and below  $2 \mu\text{g}/\text{m}^3$  in outdoor air. Similarly, when evaluating the performance of two  
202 different passive samplers, Villanueva et al. <sup>[26]</sup> reported a mean indoor air level of  $6.7$   
203  $\mu\text{g}/\text{m}^3$ . According to our results, indoor air concentrations of formaldehyde in Catalan  
204 homes and workplaces seem to be higher than those found in other locations of Spain.  
205 Levels of formaldehyde in outdoor air have been generally reported to be  $<0.001$  and  
206  $<0.02 \text{ mg}/\text{m}^3$  in remote and urban environments, respectively. <sup>[24]</sup> In Spain, outdoor  
207 formaldehyde levels analyzed in a national park were below  $2.6 \mu\text{g}/\text{m}^3$ , <sup>[27]</sup> and from  $2.0$   
208 to  $7.9 \mu\text{g}/\text{m}^3$  around a municipal solid waste treatment plant in the metropolitan area of  
209 Barcelona. <sup>[21]</sup> The fact that in both studies higher levels were found in summer than in  
210 winter, could be explained by a major biogenesis of the vegetation and a higher  
211 photochemical oxidation of hydrocarbons. <sup>[3,24]</sup>

212

### 213 ***Human health risks***

214

215 In the present study, the exposure scenario for risk assessment only considered the  
216 adult exposure through air inhalation in the following sites: i) bedroom, while subjects  
217 are sleeping, ii) living room, for other home activities, iii) workplace, during labour  
218 time, and iv) outdoors, during outdoor activities. Other activities such as cooking or  
219 travelling (by car, bus, train or subway) were not considered due to the short time spent  
220 by the Catalan general population on them. <sup>[28]</sup>

221 For the general population, inhalation exposure levels ( $Exp_{inh}$ ), using mean values, was  
222  $3.94 \mu\text{g}/(\text{kg}\cdot\text{day})$ . From the total, 53% of the contribution to total inhalation exposure  
223 came from the indoor activities at home (excluding sleeping), 26% during sleeping and  
224 19% at workplace. Only 2% of the total exposure corresponded to outdoor activities,  
225 partly because of the low levels detected and short time spent outdoors. After applying a  
226 Monte Carlo simulation, inhalation exposure levels ( $Exp_{inh}$ ) ranged from 0.77 to 21.3  
227  $\mu\text{g}/(\text{kg}\cdot\text{day})$ , being the mean value  $4.16 \pm 1.61 \mu\text{g}/(\text{kg}\cdot\text{day})$ .

228 According to the scientific literature, the main route of formaldehyde exposure is air  
229 inhalation. <sup>[24]</sup> However, other exposure pathways, such as dermal contact with textiles  
230 and personal care products, could be also important. <sup>[29-31]</sup> Claeys et al. <sup>[32]</sup> estimated the  
231 dietary formaldehyde ingestion by the Belgian population as  $0.10 \text{ mg}/(\text{kg day})$ .  
232 However, it must be taken into account that not all formaldehyde is bioavailable, and  
233 that it is not carcinogenic via oral route.

234 Regarding non-carcinogenic risks, two different  $RfD_{inh}$  were used to calculate HQ, one  
235 from the US EPA ( $9.83 \mu\text{g}/\text{m}^3$ ) and another from the Office of Environmental Health  
236 Hazard Assessment (OEHHA) ( $9 \mu\text{g}/\text{m}^3$ ). <sup>[23,33]</sup> HQ are twice times higher than the  
237 safety limit ( $HQ=1$ ) independently on the  $RfD_{inh}$  used. Using a Monte Carlo simulation,  
238 HQ mean value was  $2.17 \pm 0.62$  (ranging from 0.57 to 8.15). More than 97.5% of the

239 trials performed in the Monte Carlo simulation were above the safety limit (HQ=1) (Fig.  
240 2).

241 For carcinogenic risks, two different IUR were again proposed,  $1.3 \cdot 10^{-5}$  by the US EPA  
242 and  $6 \cdot 10^{-6}$  by the OEHHA. <sup>[23,33]</sup> The results, applying a deterministic methodology with  
243 the mean values, were  $2.66 \cdot 10^{-4}$  for US EPA's IUR, and  $1.23 \cdot 10^{-4}$  for OEHHA's IUR.  
244 Both values were above the threshold considered as acceptable ( $10^{-6}$ ), and above the  
245 range considered as assumable ( $10^{-6}$ - $10^{-4}$ ). <sup>[34]</sup> Applying the probabilistic methodology,  
246 the mean cancer risk was  $1.94 \cdot 10^{-4}$  (range:  $4.72 \cdot 10^{-5}$ - $9.45 \cdot 10^{-4}$ ). More than 95% of the  
247 simulations were above the  $10^{-4}$  threshold, which indicates an unacceptable  
248 carcinogenic level (Fig. 2). Similar findings were also reported for employees who  
249 worked in the laboratories of an adhesive manufacturer producing formaldehyde and  
250 urea-formaldehyde resin in Thailand. <sup>[35]</sup>

251 According to the guidelines from different countries, most of them focused on  
252 occupational protection regulations (Table 4), the exposure levels of formaldehyde  
253 range from  $0.02 \text{ mg/m}^3$  (8-h exposure in the US), to  $2.5 \text{ mg/m}^3$  (8-h exposure in the  
254 UK). Regarding short-term exposure, the recommendations range from  $0.123 \text{ mg/m}^3$  (1  
255 h-exposure) in Canada to  $2.5 \text{ mg/m}^3$  (15 min-exposure) in the US and the UK. The  
256 results on human health risks obtained in the present study clearly show that the daily  
257 inhalation of formaldehyde for the Catalan population, predominantly resulting from the  
258 indoor environments, is higher than threshold levels. For similar reasons, Koistinen et  
259 al. <sup>[36]</sup> considered formaldehyde as a chemical of concern when levels exceed  $1 \text{ } \mu\text{g/m}^3$ .  
260 The number and ubiquity of formaldehyde emission sources, as well as the high time  
261 ratios spent indoors, must lead public authorities to consider formaldehyde a pollutant  
262 of concern.

263

264 **Conclusions**

265

266 Formaldehyde air levels found in Catalan homes ranged from 9.65 to 47.7  $\mu\text{g}/\text{m}^3$ , and  
267 from 0.96 to 3.37  $\mu\text{g}/\text{m}^3$ , in indoor and outdoor air, respectively. At workplaces, indoor  
268 air levels ranged from 5.86 to 40.4  $\mu\text{g}/\text{m}^3$ . These levels are in agreement with those  
269 found in the scientific literature. However, the human health risk assessment clearly  
270 show that the current daily exposure to formaldehyde is too high. For most of the trials,  
271 non-carcinogenic risks were above the threshold limit ( $\text{HQ}>1$ ), and that carcinogenic  
272 risks were also not acceptable ( $>10^{-4}$ ). Despite the current study limitations (i.e., number  
273 of samples, not all daily activities or potential formaldehyde sources included), the  
274 results confirm that formaldehyde indoor levels should be regarded an issue of concern  
275 that must be taken into account by policy makers and regulatory agencies.
